

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

AUTHORIZATION.

Resolution passed by the National Eclectic Medical Association at the annual meeting, in Cleveland, Ohio, June 19, 1879:

Resolved, That this Association adopt THE AMERICAN DISPENSATORY as its STANDARD AUTHORITY.

ALEXANDER WILDER, M. D., *Secretary.*

"AUTHORITY to use for comment the *Pharmacopæia of the United States of America* (1890), Seventh Decennial Revision, has been granted by the Committee of Revision and Publication."

AUTHORITY to print selections from the *National Formulary*, has been granted by the Council of the American Pharmaceutical Association.

PREFACE.

When the undersigned, in 1880, promised his venerable friend, Prof. King, to revise the pharmaceutical and chemical sections of the American Dispensatory if it became necessary, he did not underrate the magnitude of the undertaking, and when the publishers finally decided to issue the new edition he approached the task with apprehension. It soon became evident that the work was even greater than he had anticipated, and that the pharmacy and chemistry of the book could not be revised, but must be rewritten. In consequence, in addition to his own labors, almost the entire time of Dr. Sigmund Waldbott, Librarian of the Lloyd Library, has for a long period been devoted to bibliographical research. Had it not been for the care and patience of this gentleman and the books of reference at his command, the efforts of the undersigned would have been sadly ineffectual especially in the matter of foreign chemical and historical data. The writer can not forbear adding that monetary considerations could not have induced him to undertake this enterprise, and that no material return whatever accrues to him from this publication. The exacting researches necessary have been undertaken on his part altogether as a work of love, his uttermost desire being to fulfil his promise and to credit the memory of Prof. King. If these objects have been attained, and the pharmaceutical and medical professions are also benefited by his efforts, he will be amply repaid.

J. U. L.

In addition to the entire medical section of this work, the undersigned has undertaken the portion embracing botany, botanical history, and botanical description. Most of the material pertaining to the older Eclectic practice, found in former editions of this work, has been properly credited and retained. Many of the personal statements, and all of the uses, ascribed to special formulæ of the late author, Prof. John King, M. D., have been retained intact; in a few cases, where personality demanded, his initial (K.), or the full name (John King), have been appended. The aim, however, has been to modernize the therapy of the book, and with this object special pains have been taken, whenever possible, to give fully and clearly the specific indications and uses of each remedy. A dispensatory must of necessity be largely a compilation. The uses of a remedy that is not approved by the compiler, but which is indorsed by many physicians, may consequently demand recognition which might properly be excluded from a work on materia medica intended to voice only the author's experience. The aim has been to avoid commending excessive doses, though, in order to conform to the views of some authorities, large doses of some remedies

(iii)

have been recorded. This is especially true of many compounds used according to old-style practice.

The influx of a large number of new remedies, synthetic or otherwise, has necessitated reference to some of their reputed therapeutic properties. We have therefore ascribed to them such values as have been reported by physicians through periodicals, pamphlets, and other works. In this connection it may be stated that we have not neglected to record the uses of many semi-professional proprietary compounds and the patented chemicals now in considerable favor with many physicians, especially of the regular school. Concerning these remedies, our remarks, however, have been necessarily very conservative.

Liberal use has been made of the various Eclectic Journals, State and National Transactions, and Eclectic Annuals. We have drawn freely from Webster's *Dynamical Therapeutics*; Scudder's *Specific Medication, Specific Diagnosis, and Diseases of Children*; Locke's *Syllabus of Materia Medica and Therapeutics* (Felter); and Watkins' *Compendium of the Practice of Medicine*. We also wish to acknowledge our especial obligations to the editorials of Prof. Bloyer, in the *Eclectic Medical Journal* and the *Eclectic Medical Gleaner*; the contributions of Profs. Freeman, Thomas, and Wintermute; the editorials of Prof. Ellingwood in the *Chicago Medical Times*, and the contributions of Prof. Fearn and others in the *California Medical Journal*. To these and all others who have directly and indirectly assisted in the therapy of the book, the writer herewith extends his sincere thanks.

H. W. F.

ACKNOWLEDGMENTS.

The authors of the present revision of King's American Dispensatory take pleasure in extending the following especial acknowledgments and thanks:

To the Committee of Revision and Publication of the *Pharmacopœia of the United States*, for permission (through Dr. Charles Rice) to use the *United States Pharmacopœia* for comment; to the Council of the American Pharmaceutical Association (through Messrs. W. S. Thompson and G. W. Kennedy) for permission to use formulæ of the *National Formulary*; to Messrs. Fritzsche Bros. for the use of Powers' *Essential Oils* and Schimmel's *Reports*; to Prof. Attfield (Chairman of Committee), for permission to abstract from the *British Pharmacopœia*; to Mr. Curtis G. Lloyd, for permission to use article on Coffee. For illustrative cuts credit is due William Wood & Co. (*Johnson's Medical Botany of North America*); Messrs. Parke, Davis & Co. (*Pharmacology of the Newer Materia Medica*); D. Appleton & Co. (*American Cyclopædia*); Messrs. Eli Lilly & Co. (*Lilly's Bulletin*); Messrs. Funk & Wagnalls (*Standard Dictionary*); Messrs. Johnson & Johnson (*Belladonna*, by Dr. F. B. Kilmer); Messrs. Frederick Stearns & Co. (*Illustrated Catalogue*); Dr. John King Scudder (*Eclectic Medical Journal*); J. U. and C. G. Lloyd (*Drugs and Medicines of North America*),

and Messrs. Boericke & Tafel and Dr. Charles F. Millsbaugh (*Millsbaugh's American Medicinal Plants*). With deep appreciation do we recall the cordial manner in which the late Prof. Flückiger extended the privilege of his publications, a favor we gladly accepted and freely used. It would be impractical to attempt to mention herein all the journals and standard works, both foreign and American, that have been consulted in the preparation of this publication; these when drawn from are especially credited in the text, but we can not forbear naming a few to which we are especially indebted:

Prof. S. P. Sadtler, *Handbook of Industrial Organic Chemistry*.

Husemann & Hilger, *Pflanzenstoffe*, etc.

Prof. Henry Trimble, *The Tannins*.

THE AMERICAN DISPENSATORY.

ABIES CANADENSIS.—HEMLOCK SPRUCE.

The bark and the prepared resinous exudate of the *Abies canadensis*, Michaux. (*Pinus canadensis*, Linné; *Picea canadensis*, Link; *Truga canadensis*, Carrière).

Nat. Ord.—Coniferae.

COMMON NAMES.—*Hemlock*, *Hemlock spruce*.

Botanical Source.—This common forest tree seldom rises above 75 feet, with the trunk large in proportion, straight, and covered with a rough bark. The branches are brittle and nearly horizontal, with pubescent twigs. The leaves are about half an inch in length, linear, obscurely fine-toothed, glaucous beneath, in two opposite rows. The cones or strobiles are very small, ovoid, terminal, and drooping, with a few rounded, entire scales. The foliage of this tree is delicate, bright-green above and silvery-white underneath; its timber is very coarse-grained—(G. W.).

History and Chemical Composition.—The Hemlock spruce is a well-known indigenous tree, abounding in the forests of the Northern States and Canada. The tree is found in the same latitudes and elevations as the *A. balsamea*. It flowers in May. The juice or oleoresin, known as *Canada pitch*, or incorrectly as *Gum hemlock* (for a description of which see *Pix Canadensis*), oozes from the tree, without any incisions being made, and concretes upon its external surface; the bark is removed from the tree, cut into large fragments, and boiled in water. As the resin ascends to float upon the water, it is removed by skimming and thrown into cold water. It is then placed in a coarse linen bag, and boiled a second time, to remove its impurities—(*Jour. Phil. Col. Pharm.*, Vol. II, p. 20).

It is also collected by cutting into the live tree small cotyloid depressions, into which the oleoresin exudes and from which it may be easily collected. The bark contains a large amount of tannic acid, and on this account is extensively employed by tanners, who also use an aqueous extract of the bark known as "*extract of hemlock bark*." It contains also a volatile oil, known commercially as *oil of hemlock* or *oil of spruce*, which may be obtained by boiling the boughs in water. This oil from the leaves, known also as *pine-needle oil*, has, according to Schimmel & Co. (*Semi-Annual Report*, Oct., 1893), a specific gravity of 0.907 at 15° C. (59° F.), and an optical rotation of $-20^{\circ} 54'$; and its known constituents are *pinene*, *bornyl acetate*, and *cadinene*. Two preparations now largely used are *Kennedy's White Pinus Canadensis* and *Kennedy's Concentrated Extract of Pinus Canadensis*. The latter is red, and is used both externally and internally; the former is white, does not stain, contains alum and zinc sulphate, and is designed for external use only.

Action, Medical Uses, and Dosage.—A strong decoction of the bark of this tree is beneficial in *leucorrhœa*, *prolapsus uteri*, *prolapsus ani*, *diarrhœa*, etc., administered internally, and used in enema; it is likewise of service as a local application in *gangrene*, and in *aphthous*, and other *oral ulcerations*.

The essential oil of this tree, the oil of hemlock, has occasionally been used by pregnant females to cause miscarriage, but serious effects are apt to follow therefrom. As a liniment this oil has been used in *croup*, *rheumatism*, and other affections requiring a stimulating local application. The essence (oil) of hemlock is diuretic and highly stimulant. Dr. W. K. Everson states it to be a

superior remedy in gastric irritation to allay vomiting in *cholera morbus*, etc. The dose is 5 or 10 drops in water, every 10 or 20 minutes, until relief is afforded.

The alcoholic preparations of this drug usually pass under the name of *Pinus canadensis*. Such preparations are of much value where a mild stimulant and astringent is required, and especially in *catarrhal disorders* of the mucous tissues, with marked pallidity and relaxation. It is likewise of value in *passive hemorrhages*, and is useful topically in *scalds* and *burns*. Tincture, 5 to 30 drops; specific *Pinus canadensis*, 2 to 10 drops, preferably in equal parts of water and glycerin; the oil, 2 to 5 drops.

Specific Indications and Uses.—General asthenic state, with feeble digestion, vascular weakness, and pale mucous membranes; broncho-pulmonary irritation, with profuse secretions; coughs and colds; renal torpor; pyrosis and gastric irritation, with vomiting and diarrhoea; some cutaneous affections. Never to be used in inflammatory or sthenic conditions.

ABIES NIGRA.—BLACK SPRUCE.

The branches of the *Abies nigra*, Michaux, and the essence obtained from the same.

Nat. Ord.—Coniferae.

COMMON NAMES.—Black spruce, Double spruce.

Botanical Source and History.—This tree grows in the northern parts of this continent, and in elevated situations in the Middle States, especially in the woods of mountainous districts. It is a pyramidal tree and attains the height of from 40 to 80 feet, having short, erect, rigid, very dark-green leaves. The cones are 1 or 2 inches long, ovate, reddish-brown in color, with their scales rounded, entire, wavy, and toothed at the apex.

Action and Medical Uses.—An aqueous decoction of the young branches, strained and concentrated, forms the well-known Essence of Spruce, which enters into the formation of Spruce Beer, an agreeable and salutary summer beverage, possessing diuretic and anti-scorbutic properties, and valuable on board ships. Spruce Beer may be made as follows: Take of ginger, sassafras bark, and guaiacum shavings, each, 2 ounces; hops, 4 ounces; essence of spruce, 10 ounces; water, 4 gallons; mix them and boil for 10 or 15 minutes, then strain. Add 10 gallons of warm water, 3 quarts of molasses, and 12 fluid ounces of yeast, and allow it to ferment. While fermentation is going on, put the fluid in strong bottles and cork them well.

ESSENCE OF SPRUCE is a viscid, molasses-like liquid, having a somewhat sour and bitterish, astringent taste.

ABRUS.—ABRUS.

The seeds and root of the *Abrus precatorius*, Linné.

Nat. Ord.—Leguminosæ.

COMMON NAMES.—Wild liquorice, Indian liquorice, Jequrity.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 77.

Botanical Source.—A twining shrub, bearing rose-colored papilionaceous flowers, clustered in long, one-sided racemes. The shrub attains a height of from 10 to 15 feet. The leaves are compound, abruptly pinnate, borne on a short petiole, and are divided into from 20 to 30 linear or oblong leaflets of a pale-green color, glabrous, entire and obtuse. The fruit is a long, oblong, rhomboid legume, containing from 4 to 6 seeds. The pod is a little over an inch in length, and terminates in a short beak.

History.—In India the root is official as a substitute for liquorice root, though Dymock (*Mat. Med. Western India*) denies the statement made by Ainslie and others that the root exactly coincides with that of common liquorice, and that it is sold for that drug in the Bengal bazaars. He states that the root bears but little resemblance to the liquorice root, but that the leaves are sweeter and may yield a fairly good extract. He further says that true liquorice root can be so easily collected and is so abundant as an article of commerce in Bombay that the substitution of abrus for that drug would be both inexpedient and expensive. This plant

is known in Bengal as *gunj*, *gunja*, *goontch*, *kunch*, and *gurgonje*, and is called *ratti* in Hindustan. Though varying slightly in weight, the seeds are used by the Indian goldsmiths as standard weights, 1 *gunja* being equal to about 1.84 gr. Troy. According to Dutt a *gunja* is equal to 2 grains of wheat, 8 of barley, 4 of rice, or 18 mustard seeds. *Abrus* seeds are the agents by which the Chamâr or "Native Skinner" caste of India carry on the felonious poisoning of cattle for the purpose of securing their hides. This is done by means of small spikes, called *sui* (needles) or *sutari* (awls), which are prepared by soaking the awl in a thin paste of the water-soaked, pounded seeds, and then drying the weapon in the sun, after which it is oiled and sharpened upon stone, affixed in a handle, and then used to puncture the skin of the animal.

Abrus has been used for centuries by the Hindus, who employ the seeds as an external application in skin affections, ulcers, and to excite artificial inflammation in fistulæ. Sanskrit authors mention both the white and red seeds, and describe the root as an emetic. Mahometan writers speak of its aphrodisiac qualities. As early as 1592 Alpinus found the Egyptians using the seeds for beads, and occasionally eating them, though they considered them unwholesome as food. It is asserted that Indian singers chew the leaves of the white-seeded variety for the cure of hoarseness. The seeds, under the native name of *jequiriti* or *quequiri*, were introduced into modern medicine from Brazil, where they have long been in use among the natives as a remedy for pannus and trachoma. The shrub is indigenous to India and Brazil, and is naturalized largely throughout the tropics. The drug was introduced into England in 1862, where it excited but little attention until revived by DeWecker in 1882.

Description—**SEMEN ABRIS**.—Crab's eye, Prayer beads, Jumble beads. *Jequirity* seeds are about one-fifth inch long, subspherical, hard, and of a glossy-scarlet color, with the exception of a black spot surrounding the hilum. They have a taste somewhat resembling common beans and are without odor. Dymock mentions white, purple, yellow, and blue seeds, of which only the white is common.

RADIX ABRIS.—The root is twisted, long, and cylindrical, varying from $\frac{1}{2}$ to 1 inch in thickness; reddish-brown externally, the internal or woody portion being yellowish. It is porous and breaks with a short, fibrous fracture. The bark is thin. The root has but little odor, that being somewhat disagreeable at first, but is bitter and acrid to the taste, afterward slightly sweetish, resembling, to a slight extent, that of common liquorice root.

Chemical Composition.—According to Berzelius, a substance closely resembling *glycyrrhizin* may be obtained from the leaves and branches. The root contains both this principle and sugar. By treating the seeds with boiling alcohol Warden (1882) obtained an inert, white, crystalline body, slightly soluble in cold water, which has been named *abric acid* ($C_{12}H_{22}N_2O$). A mixture of proteid principles, of a light slate color, called *abrin*, was also obtained by Warden, of Calcutta, which, according to Buffalini (1886), is a violent cardiac poison. This body is found also in the root and stems. Rigaud and Dusart (1883) succeeded in getting an alkaloid from the seeds (thought, however, to be a decomposition product), which contain also a fixed oil, lecithin, and cholesterin. No irritating principle has yet been isolated from the seeds unless it should prove that two proteid bodies, one a paraglobulin, the other an albumose, are the active agents. According to Sattler the violent action of *jequirity* depends upon a "pathogenic micro-organism," developed in the infusion, which has the physiological property of vegetating upon the conjunctiva, thereby developing a ferment which is capable of producing the artificial inflammation. Warden and Waddell, however, believe the activity to be due, not to a bacillus, but to a soluble ferment embodied in *abrin*, as they have found the latter substance to be much more active than the seeds. *Abrin* is probably the same body as Bruylant's and Vinneman's (1885) *jequiritin*. Moist heat is said to render it inactive. Whatever may be the exciting agent, it is known that the infusion used must be at least a day old, as the freshly-made preparation is totally incapable of producing the purulent condition known as "*jequirity ophthalmia*."

Action and Medical Uses.—The seeds when taken into the stomach of man are said to be wholly inert. Large quantities of them are eaten by the Hindus to prevent fecundity. Half a seed rubbed in a little water, thrown into the thigh of

a cat, caused the death of the animal in less than 24 hours (Warden). Jequirity kills the lower animals, acting somewhat like septicæmia, not unlike that produced by serpent venom. An infusion of the strength of 1 to 20 instilled into the eye of a rabbit produced a violent inflammation, resulting in complete destruction of that organ and gangrene of the lids. A false membrane was created with much œdema and corneal ulceration. The salivary glands became swollen, destructive suppuration of the maxillary glands taking place. Hypodermatically injected under the skin of animals, it produced gangrenous abscesses, and when thrown into the blood induced "virulent tonical phenomena" (Carnil and Berlioz, 1883). The infusion applied to the human eye several times a day will in a few hours produce an active conjunctival irritation, followed within 20 hours by severe inflammatory action, accompanied with such great swelling and œdema that the lids can not be voluntarily separated. This is accompanied with pain and rise of temperature. On about the third day suppuration ensues and continues copiously until about the eighth day, when it begins to subside. The whole period of action covers about two weeks, leaving the cornea somewhat hazy.

Abrus is a dangerous drug, and is employed only in eye disorders requiring the substitutive action of a violent drug inflammation to overcome the existing pathological inflammation. For this purpose it is employed in *scrofulous pannus* and *granular ophthalmia* or *trachoma*. In the latter disease it should only be used in old cases. It should, however, be very cautiously used, and only after all other means have been exhausted, for it not only provokes violent conjunctival inflammation, but is likely to destroy the corneal structures. It has been used successfully in *ulcers* and *corneal abscesses*. *Stricture of the nasal duct* has been reported by Murrell from the use of this drug. It is contraindicated, according to Dr. Kent O. Foltz (*Dynamical Therapeutics*), in *recent granular conjunctivitis* exhibiting velvety surfaces or having but slight secretion, or when there is a *corneal slough*; also in *dacro-cystitis* and *phlegmonous inflammations of the tear-passages*.

An emulsion prepared from the red hulls of 200 decorticated jequirity beans macerated in a small quantity of water for 24 hours and then triturated to a smooth paste in a mortar, adding sufficient water to make 800 grains of the finished product, was found of service by Shoemaker in the treatment of *ulcers*, *lupus*, and *epitheliomatous growths*. The emulsion was applied with a brush. Several modes of preparation of the seeds for use in ocular therapeutics are given, one of which is to rub in a mortar 9 seeds in an ounce of cold water, after which an ounce of hot water is added. Allow the solution to stand 24 hours and cool, and then filter. At Will's Eye Hospital, Philadelphia, 9 grains to the ounce are employed, with the addition of 4 grains of boric acid to prevent decomposition. Some oculists prefer to use abrus seeds in an impalpable powder.

Related Drug.—*Cassia Absus*, Linné, furnishes flattish, shining-black, ovate-oblong seeds, which have been used in India like jequirity. A plaster prepared from them is used on *wounds* and *sores* particularly of the penis. For *purulent conjunctivitis*, the seeds are prepared by enveloping them in dough and placing within an onion and baking. One grain is employed. Dr. G. Smith, of the Madras Eye Infirmary, declares it a dangerous and painful application to *granular lids* and other *ophthalmias* (Dyuoock).

ABSINTHIUM (U. S. P.)—ABSINTHIUM.

The flowering tops and leaves of the *Artemisia Absinthium*, Linné. (*Absinthium vulgare*, Lamarck).

Nat. Ord.—Compositæ.

COMMON NAME.—Wormwood.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 156; Woodville, *Med. Bot.*, 22; Willdenow, *Sp. Plant.* III., 1844.

Botanical Source and Description.—Wormwood is a perennial plant, sending up in the spring, from a stout rootstock, several bushy, herbaceous stems, somewhat woody at the base and from 1 to 4 feet in height. These die down as winter approaches, but the strong, woody base (above the root) remains several years, each year giving off new shoots. There are two kinds of leaves—radical and stem leaves; the former being from 6 to 8 inches long, the latter from 1 to 3 inches. The stem leaves are nearly orbicular in outline and deeply incised, giving

rise to that form of leaf known botanically as bi- or tri-pinnatifid. The flowers are borne in a paniculate raceme, are tubular, hemispherical, pale-yellow or buff in color, numerous and nodding. The whole plant, except the woody portions, is covered with a whitish, silky pubescence, giving to it a beautiful silver-gray color. To the touch it is exceedingly soft and velvety. The odor is strongly aromatic, being intensified when the herb is bruised; and to the taste the plant is intensely bitter, with a persistently bitter aftertaste. Cultivation renders it milder to the taste and less disagreeable to the sense of smell. The *U. S. P.* thus describes this drug: "Leaves about 5 Cm. [1.97 in.] long, hoary, silky-pubescent, petiolate, roundish-triangular in outline; pinnately two- or three-cleft, with the segments lanceolate, the terminal one spatulate; bracts three-cleft or entire; heads numerous, about 3 Mm. [0.12 in.] long, subglobose, with numerous small, pale-yellow florets, all tubular and without pappus; odor aromatic; taste persistently bitter"—(*U. S. P.*).

History.—Wormwood is distributed throughout various parts of Europe (being plentiful in the Crimea), Siberia, and the highlands and mountainous districts of Barbary. It is found also in Newfoundland and the United States, being naturalized throughout the mountainous elevations of the New England States. It is cultivated in gardens both in this country and on the continent. In Germany it is employed as a substitute for hops in the making of *Wermuth beer*, and used by the French in preparing the liquor *absinthé*, an alcoholic cordial containing the oil of wormwood and other aromatics, as melissa, anise, marjoram and angelica, in the form either of oils or extracts. The plant should be gathered during its flowering period, which is from June to September, the best time probably being throughout July and August. The woody stalks should be rejected. The dried herb fully retains its virtues, which are imparted to both alcohol and water. Wormwood steeped in vinegar and water has long been popular among the laity as a local application for injuries.

Chemical Composition.—Braconnot (1815) found in this plant two azotized substances, one intensely bitter, the other insipid; a volatile oil, an intensely bitter resin, a green resin (probably chlorophyll), albumen, woody fibre, starch, potassium absinthate and nitrate, and *absinthic acid*, which, however, subsequently proved to be *succinic acid*. The plant also contains acetic and malic acids. The odor of wormwood is due mainly to a dark-green (sometimes yellowish or brown) oil, of an acrid taste, and possessing in a high degree the odor of the plant. It is known in commerce as *Oleum Absinthii*, or oil of wormwood. This oil consists principally of *absinthol* ($C_{10}H_{16}O$), which yields *cymene*, water, and a resinous body when heated with chloride of zinc or phosphorus pentasulphide (Wright). A larger quantity of oil is obtained from the dried than the green plant, the amount being also diminished by circumstances of growth, yielding a lesser quantity when the plant is cultivated or when grown in warm regions (Zeller). By proper means it may be obtained colorless, and should be protected from the light and the atmosphere, which impart to it a darker hue and render it somewhat syrupy and viscid. The peculiar bitterness of wormwood is due to *absinthin* ($C_{15}H_{20}O_4$, Senger, 1892), a substance isolated in an impure form by Caventou in 1828. Mein (1834) obtained it in white prismatic crystals.

Absinthin.—**PREPARATION:** Precipitate a decoction of *Artemisia Absinthium* with tannic acid in slight excess. Wash the precipitate in cold water and then digest with excess of litharge. Dry the mixture and exhaust the powder with boiling alcohol, filter, treat with animal charcoal, filter again and evaporate. The residue assumes a crystalline form in time. If not pure it can be obtained nearly white by dissolving in alcohol, treating with animal charcoal, filtering and evaporating again.

Action, Medical Uses, and Dosage.—Physiologically both oil of wormwood and extract of absinth act upon man as nerve depressants. Less than drachm doses produced in rabbits and dogs tremors, spasmodic muscular action of a clonic character, intoxication, and loss of sensibility. Larger doses (from 1 to 2 drachms) produced violent epileptoid seizures, in some instances resulting fatally. Small doses administered to man act as a gentle stimulant, larger doses produce headache, while still larger doses induce cerebral disturbances and clonic hysteroidal convulsions (Lancereux). Victims of *absinthism* are subject to disturbed rest,

with disagreeable dreams, awakening in the morning with sickness and vomiting. A chronic intoxication ensues that is more fearful in its effects than that resulting from the abuse of alcoholics. A conspicuous feature is the tendency to epileptoid attacks. Both physical and mental power is seriously impaired and the sexual system weakened to such an extent that virile power is lost in the male, while a premature menopause is a common result in the female. It is also said to produce a peculiar hyperæsthesia, most marked in the integument of the hypogastrium.

Absinthium possesses decided medicinal qualities, acting with considerable force upon the cerebrum and the sympathetic nervous system. It has been employed with success for the expulsion of the *intestinal parasites*—*ascaris vermicularis* and *lumbricoides*. Previous to the introduction of cinchona it was largely employed in *malarial intermittents*, and was at one time a popular remedy for *jaundice*. In small doses it is a stimulant tonic, improves the appetite, and is useful in atonic states of the gastro-intestinal tract, as *atonic dyspepsia*, especially when due to alcoholic excesses, in *flatulent colic*, and in *obstinate diarrhæa*. Large doses are apt to irritate the stomach and increase the action of the heart and arteries. It has been employed with good results in *amenorrhæa* and *leucorrhæa* when due to debility. It is principally used, however, as a warm fomentation for *sprains*, *bruises* and *local inflammations*. For this purpose it may be steeped in water, or better in vinegar and water, and applied as hot as can be borne. It has also been advised as an external application in chronic affections of the abdominal viscera, either in the form of tincture, infusion, or poultice. Its tonic properties are marked. Combined with a fixed alkaline salt, it is said to prove powerfully diuretic. The oil is narcotic. Of the infusion (3i to Oj), 1 to 2 fluid ounces; of the oil, from 1 to 5 drops; the powder, 10 to 20 grains.

Related Species.—*A. tridentata*, Nutt.; *Sage brush*. Hab. U. S., from Rocky Mountains westward. The wild sage is deserving of notice. In the western states it is reputed by physicians to be a good emmenagogue, and is in common use by the people as a remedy for *putrid angina*, *arthritic rheumatism*, and *diphtheria*. The oil, mixed with olive oil to form a liniment, is largely employed by them in *erysipelas*, *contusions*, *sprains*, and *swellings* (Ed. E. M. J., 1877, p. 237). According to Dr. Roberts (E. M. J., 1877, p. 415) the oil is a valued remedy in *flatulent colic*, and the leaves used as a fomentation for *abscesses* promote the rapid formation of pus and impart such a healthy tone to the parts that the disease is quickly brought to a termination with the least possible destruction of tissue. An infusion is used by the Indians for *colds*, *headache*, and to expel *intestinal parasites* (Palmer). *A. trifida*, Nuttall, and *A. arbuscula* are dwarf species having like properties.

A. filifolia, Torrey.—Called *Southern wood* in its habitat, U. S. west of Rocky Mountains. Used by the Indians for *tumefactions* and *bruises*. Contains an essential oil valuable for liniments (Palmer).

A. Ludoviciana, Nuttall; *Western mugwort*.—N. W. U. S., from Great Lakes to Pacific Ocean and southward. The fruit of this and the next species used by the Indians as an article of food. This species in infusion is supposed to promote the growth of the hair, and is employed by the Pah Utes to facilitate *labor*, and as a remedy for *epistaxis* (Maisch, *Amer. Jour. Pharm.*, Vol. LII, p. 69).

A. Dracunculoides, Pursh.—Illinois to Pacific coast northward to British dominions, and southward to Arizona and Arkansas. Fruit used as food by the Indians. The bruised plants act as a topical irritant, and an infusion of them produces diaphoresis.

A. Drancunculus, Linné; *Tarragon*.—Cultivated in southern Europe, Tartary, and Siberia. A bitterish, aromatic, anise-odorous plant, the volatile oil of which is chiefly anethol ($C_{10}H_{12}O$).

A. Maritima var. *Stechmanniana*, Besser; *Wormseed*.—Europe and Asia. In saline soils, along seacoasts and in salty marshes. Source of Santonin (*Pharmacographia*).

A. Abrotanum, Linné; *Southern wood*; *Old man*.—Hab. southern Europe and western Asia. Cultivated in gardens in North America. An aromatic bitter, with the odor of lemons, and is said to contain *abrotins*, a crystallizable alkaloid (Craveri).

A. vulgaris, Linné; *Mugwort*.—Europe, northern Asia and northern Africa. Naturalized and cultivated in the United States. The root, which contains volatile oil, tannin, and an acrid resin, is used for medicinal purposes in Europe. Emmenagogue and German remedy for *hysteria* and *epilepsy*.

A. Pontica, Linné; *Roman wormwood*.—Hab. central Asia and southern Europe. Used as a substitute for common wormwood, though not esteemed so valuable.

A. frigida, Willdenow; *Sierra salvia*, *Mountain sage*.—Colorado. Probably contains some absinthin (F. A. Weiss, 1890).

A. Chinensis. } Source of Chinese *Moza*.
A. Indica. }

A. Abyssinica, Olivier; *Tshuking*, *Zerechit*.—Abyssinia. The bitterish, aromatic flowers contain a bitter principle, tannin, and essential oil (Dragendorff).

ABSTRACTA.—ABSTRACTS.

For a period preceding 1880, a class of compounds known as powdered solid extracts came into more or less conspicuity largely through the efforts of manufacturing pharmacists.

Powdered extracts were made by reducing an ordinary solid extract by evaporation to a concentrated condition, and then thickening the mass with a harmless powder, or the respective powdered, crude drug, and then drying the mixture, or by drying the extract intact, as necessity prompted.

The Pharmacopœial Committee of 1880, aiming to supply a class of official preparations embracing the qualities of powdered solid extracts, introduced a line of similar preparations under the name *Abstracta* or *Abstracts*.

These were made by evaporating percolates of the respective drugs, and incorporating the residue of each with enough milk-sugar to bring to a standard, in which one part of the dried mixture represented two parts of the drug.

Abstracts did not become popular, and neither replaced the commercial powdered extracts nor established themselves in the graces of the medical or the pharmaceutical professions. This failure was mostly due to the fact that the Pharmacopœia is a follower, and seemingly can not create a trade-demand if none exists. At the same time it was found that some of the formulæ were not practical; for example, as when an attempt was made to dry the oily percolate of *Nux vomica*. The succeeding Pharmacopœial Committee (1890) wisely dropped the list.

ACACIA (U. S. P.)—ACACIA.

"A gummy exudation from *Acacia Senegal*, Willdenow" (U. S. P.). The concrete juices of other species are also included under the commercial name Gum Acacia.

Nat. Ord.—Leguminosæ.

SYNONYMS: *Gum arabic*, *Gum acacia*, *Gum mimosa*, *Gummi mimosæ*, *Gummi arabicum*.

ILLUSTRATION: *Acacia Senegal*, Bentley and Trimen, *Med. Plants*, 94; *A. vera*, Willdenow, *Spec. Plant*, iv., 1805.

Botanical Source.—The trees and shrubs yielding this gum are numerous, and all have leaves of the bipinnate variety and long spikes or globular heads of flowers, generally of a yellow color. They are more or less thorny, from the fact that the stipules are often transformed into spines. They all delight in dry, sandy situations, and will often be found where other shrubs and trees can not exist.

The *Acacia Senegal* of Willdenow (*A. verec* of Guillemain and Perottet and *Mimosa Senegal* of Linné) is a moderate-sized tree, usually about 20 feet high. It has a crooked stem with a grayish bark, and is much branched, the limbs being scattered over or covered with a purplish or yellowish-green bark. The leaves are smooth and bipinnate, the pinnæ in two pairs, with a gland between them. The leaflets are oblong-linear and arranged in eight or ten pairs. The spines are sharp and in two pairs. The flowers, which are small and yellow, are densely crowded on axillary, stalked, globose heads, usually two together. The fruit is a smooth, compressed, moniliform legume, of a light-brown color, and usually about 5 inches long, containing about 6 flattish seeds.

The *Acacia vera*, Willdenow (*A. arabica* of Willdenow; *A. nilotica*, Desfontaines; *Mimosa arabica*, Roxburgh). A small, undersized tree or shrub, which occasionally, however, attains a height of about 40 feet, with a trunk from 3 to 4 feet in circumference. The thorns are stipulary, sometimes long, sometimes short, or almost wanting. The flowers are small, yellow, and in globose heads. Each flower has a five-cleft corolla and numerous, distinct stamens.

Botanical History.—The *Acacia Senegal* inhabits Africa from Senegal eastward to Egypt. It is called *Hashab*, and yields the most valuable gum, that coming from Dejera, in Kordofan, being the best product. It is known as *Hashabi* gum. The gums yielded by this species are known as the Kordofan and Senegal gums. It constitutes large forests north of the River Senegal.

Acacia vera (*A. arabica*). Near the Nile this tree is known as the *Santi* or *Sont*, Egyptian thorn, or Egyptian gum arabic tree. It inhabits Egypt, Arabia,

India, and is found abundantly as far south as Abyssinia, and westward to the regions of the Senegal. It produces an inferior brownish or reddish gum.

Jackson (*Account of Morocco*, 8d ed., p. 137) says:

"Of the trees from which gum arabic is obtained, and which inhabit the southern parts of Asia and the upper portions of Africa, the *A. arabica* is the most common. Several species are said to yield the gum, and probably contribute to supply that found in commerce, but that above-named furnishes the principal part of it. The gum flows naturally from the bark of the trees, in the form of a thick and rather frothy liquid, and speedily concretes in the sun into tears; sometimes the discharge is promoted by wounding the trunk and branches. The secretion is most abundant in dry, hot seasons, and among old stunted trees, especially after a rainy season has softened their bark, and rendered it apt to split during the succeeding hot weather. The more sickly the tree appears the more gum it yields; and the hotter the weather the more prolific it is."

Description and Tests.—The *U. S. P.* thus describes *Acacia*: "In roundish tears of various sizes, or broken into angular fragments, with a glass-like, sometimes iridescent fracture, opaque from numerous fissures, but transparent and nearly colorless in thin pieces; nearly inodorous; taste insipid, mucilaginous; insoluble in alcohol, but soluble in water, forming a thick, mucilaginous liquid. *Acacia* should be slowly but completely soluble in 2 parts of water. This solution shows an acid reaction with litmus paper, yields a gelatinous precipitate with basic lead acetate T.S., ferric chloride T.S., or concentrated solution of sodium borate, and does not reduce alkaline cupric tartrate V.S. The powder is not colored blue (absence of starch) or red (absence of dextrin) by iodine T.S."—(*U. S. P.*).

The best quality of gum arabic—that known as Kordofan gum, Turkey gum, or White Sennar gum—is perfectly colorless, of a shining, conchoidal, vitreous fracture, opaque in mass, but transparent in small fragments, hard but pulverable, inodorous, and of a faintly sweetish and viscous taste. It is generally in tears, round or angular, and seldom larger than a hazel nut. The very pale, yellowish-white, yellowish-red, or brownish tears belong to the second quality, and may be rendered colorless by the action of sunlight, or when treated with chlorine water. The specific gravity is from 1.33 to 1.52. It almost invariably forms a white powder.

Cold or hot water dissolves its own weight of gum arabic, forming a thick mucilaginous solution, and from which the gum may be obtained by evaporation, or by precipitation with excess of alcohol; the concentrated solution may be kept much longer than the dilute, which latter, especially in warm weather, undergoes the acetous fermentation. The gum is also soluble in solutions of the pure alkalies, lime water, and dilute acids. Alcohol does not dissolve it, neither does ether or the oils. When boiled with sulphuric acid an unfermentable variety of sugar is formed; but with nitric acid it passes into mucic, malic, and finally into oxalic acid.—(*Ed.*) Treated with a solution of the neutral perchloride of iron, the mucilage of gum arabic becomes a light reddish jelly; with a solution of borax it forms a firm, colorless jelly, which is liquefied by powdered sugar; and, with a solution of sugar, it furnishes, by desiccation, a clear, hard, amorphous mass. Its decomposition is readily effected by the strong acids. The gums known as Gedda, Jiddah, and Turic gums were varieties of Kordofan gum.

Gum arabic does not deteriorate if kept dry, but its concentrated mucilage, after a long time, will become sour (acetic acid). Hot water is said to hasten this fermentation, if employed in making the mucilage. Dilute solutions of the gum become moldy. A few drops of sulphuric acid added to it—the solution being poured off from the resultant precipitate of calcium sulphate—is said to prevent this change—(*Am. Jour. Pharm.*, 1872).

Varieties—**SENEGAL GUM.**—This gum is one of the chief productions of the French colony of Senegal, being gathered by the Moors and negroes in the section north of the river of that name. It is gathered from November to July and shipped to Bordeaux, France, and some of it reaches America. It occurs in larger pieces than the Kordofan gum, and is often oblong or vermiform in shape. While some of it is colorless most of it is yellowish, reddish, or brownish in color. It is stated that it is sorted into several grades in America. Several species of *Acacia*,

among them the *A. Senegal*, abounding in large forests, yield this gum. It breaks less easily, and seldom exhibits the fissures observed in the best variety, and while differing in appearance from the Egyptian gum, though being obtained, in part at least, from the same species, it does not exhibit different optical or chemical properties from those of the better variety. It was introduced by the Dutch, though its commerce is now controlled by the French.

MOROCCO GUM, Mogador or Barbary gum.—This gum is derived from the *A. nilotica*, Desfontaines (*A. arabica*, Willdenow), and derives its name from the port (Mogador) from which it is shipped from Morocco. It is gathered in July and August in the provinces bordering on Morocco, and in part from Timbuctoo. This gum comes in moderately large tears, occasionally worm-shaped, vitreous within, and crackles when exposed to a warm temperature. It has a nearly uniform, faintly brown, or dusky color, and is fissured externally. It dissolves completely in water.

CAPE GUM.—Exudes spontaneously, from the *A. horrida*, Willdenow, or very common Doornboom tree of South African forests. It is produced as tears or fragments, of a pale-amber color. It is shipped from Cape Colony by way of the Cape of Good Hope, and is regarded as an inferior gum.

AUSTRALIAN GUM, Wattle gum.—This gum occurs in large globular, transparent tears or masses, which are hard and of a pale yellow, amber, or brown color. It dissolves completely in water, producing a mucilage which is very adhesive, and less liable than other gums to crackle when dry. Tannin from the bark is apt to be present on this gum. It is the product of several species, among them *A. pycnantha*, Benthams; *A. decurrens*, Willdenow (*A. mollissima*, Willdenow), and *A. homalophylla*, A. Cunningham, the fragrance of the latter earning for its wood the name of "violet wood."

INDIA GUM, East India gum.—A gum has been introduced into commerce termed *Gum of India*, which is used for dressing cloths, etc. Being cheaper than gum arabic it is used to adulterate this gum, but it is unfit for pharmaceutical purposes. It reaches London in cases of about 535 pounds; the picking is done in France, where the whitest tears are mixed with gum arabic and gum Senegal. The method to detect this adulteration is to mix 30 grains of the suspected article with a pint of cold water, and allow the mixture to rest. In place of a homogeneous solution, a thick, transparent, tenacious magma is obtained, insoluble in a large amount of water. Though called *India gum* it all goes from Africa to Bombay, and from thence is shipped to other parts.

SUAKIN GUM, Savakin gum, Talca or Talha gum.—A very brittle gum, usually semi-pulverulent, obtained from the *A. stenocarpa*, Hochstetter, and the *A. Seyal* var. *fistula*, Schweinfurth. It is composed of colorless and brown gums, mixed, and is collected near the western shore of the Red Sea and delivered at the port of Suakin, from which it derives its name. It is sometimes partially insoluble, but gives a pasty magma with water.

SENNAAR GUM, Sennari gum.—A gum resembling Kordofan gum in beauty, but less valuable, is gathered on the Blue Nile and exported by the way of Sennaar. This gum is known by the native term *Hashabi el Jesire*. It is quite common in commerce.

MEZQUITE GUM.—Dr. G. G. Shumard introduced to the profession a species of gum discovered in Texas and New Mexico, and which answers the purpose of gum acacia, forming a beautiful mucilage with water. It exudes spontaneously from the Mezquite tree, in a semifluid state, and hardens in a few hours, forming lumps of various sizes and colors, which whiten by exposure to sunlight, and finally become translucent and often filled with minute fissures. It is called *Gum mezquite*, *mezquit*, *muckee*, *musquit*, etc. The tree from which it is obtained is the *Algarobia glandulosa*, Torrey and Gray (*Prosopis dulcis* of Kunth, or *P. juliflora* of DeCandolle). It is from 25 to 40 feet high.

The tree yielding this gum is also found in California and Mexico, and south to Chili and the Argentine Republic. The uses of mezquite gum are identical with those of acacia.

HOGG GUM, Doctor gum.—(Not *Gum Hogg*, or the East Indian *Kathira*, from *Cochlospermum Gossypium*, De Candolle).—This gum occurs in irregular fragments or tears, sometimes transparent and reddish in color, at other times opaque. It is

derived either from *Rhus Metopium*, Linné, or *Moronoba coccinea*, Aublet, possibly from both. Water only partially dissolves it.

CHAGUAL GUM.—From *Puya lanuginosa*, Molina (*Pourretia lanuginosa*, Ruiz et Pavon). *Nat. Ord.*—*Bromeliaceæ*.—A Chilean product, of a thick, mucilaginous consistence and acidulous character, and but partially soluble in water. Borax does not precipitate it from solution, but precipitation may be effected with acetate of lead.

Admixtures.—Gum arabic is often adulterated with the inferior grades of gum, and in powdered form with starch or flour (which, however, will respond to the iodine test), besides fragments of dextrin. The latter may be detected by Trommer's test, which gives a precipitate of cuprous oxide upon standing.

Chemical Composition.—Gum arabic is generally accepted to be a mixture of salts of calcium, magnesium, and potassium formed by the union of these elements with *arabic acid*. The gum is chiefly composed of the calcium arabate. *Arabic acid*, known also as *gummic acid*, forms salts containing an excess of acid. It is considered identical with the *metapeptic acid* of Frémy, and is obtained from a solution of the gum, acidulated with chlorhydric acid, by precipitation with alcohol. Before drying *arabic acid* is soluble in water, but after drying it becomes *metagummic acid*, and refuses to dissolve in either hot or cold water unless they be alkalinized. Both gum arabic and *arabic acid* are known as *arabin*. Continued heating with dilute sulphuric acid changes arabin into sugar, while oxidation by means of nitric acid results in the production of mucic, oxalic, saccharic, and tartaric acids. *Arabinose* ($C_{12}H_{22}O_{11}$) is produced by means of dilute sulphuric acid from those gums which yield none or but little of mucic acid.

Action, Medical Uses, and Dosage.—Gum arabic is nutritive and demulcent, and exerts a soothing influence upon irritated or inflamed mucous tissues, by shielding them from the influence of deleterious agents, atmospheric air, etc. On this account it has been used in *diarrhœa* and *dysentery*, to remove tenesmus and painful stools, in *catarrh*, *cough*, *hoarseness*, *gonorrhœa*, *ardor urinæ*, etc.—(*Coze*.) It may be given almost *ad libitum* in powder, lozenge, or solution, alone or combined with syrups, decoctions, etc. In acute diseases, where it becomes necessary to use the lightest and most readily digested food, there is no article, probably, equal to gum arabic. It may be used for this purpose by dissolving half an ounce of the powdered gum in 5 ounces of water, and sweetening with loaf-sugar, of which a tablespoonful may be given every 2 or 3 hours; in low stages of *fever*, in *typhoid fever*, and wherever a mild stimulant is required, 1 ounce of a saturated solution of camphor in sulphuric ether may be added to the above, and administered in the same way; it is diuretic, promotes the action of the absorbents, and does not materially increase arterial action. Equal parts of pulverized alum and gum arabic form a good preparation to check hemorrhages from small cuts, wounds, etc. Externally, the application of its solution to *burns* and *scalds* has proved serviceable, repeating it until a complete coating is secured. It is likewise much used for compounding pills, lozenges, mixtures, and emulsions; also for administering insoluble substances in water, as oils, resins, balsams, camphor, musk, etc.

MUCILAGE OF GUM ARABIC.—To 4 ounces of finely pulverized gum arabic add, very gradually, a pint of boiling water, and rub the whole until perfectly blended. Dose, *ad libitum*. When gum arabic is adulterated with cherry gum, it is not easy to form a good mucilage; the *cerasin* of the cherry gum will cause it to be ropy. (For the official mucilage, see *Mucilago Acaciæ*).

Related Products.—*Flindersia maculosa*, F. von Mueller (*Elæodendron maculosum*, Lindley). *Nat. Ord.*—*Meleaceæ*. *Spotted tree*, *Leopard tree*. This tree of New South Wales and Queensland is known by the above names on account of its spotted bark. The leaves are greedily devoured by sheep in times of drought. This tree exudes from the stems and branches during the summer months masses as large as pigeon eggs, of a clear amber-colored gum, having a pleasant taste, and which is eaten by the aborigines, and commonly employed by the bushmen for *diarrhœa*. It forms a good adhesive mucilage, and reminds one of a good quality of East India gum acacia. About 80 per cent of *arabin*, but no *metarabin* has been found in it—(*J. H. Maiden, Useful Native Plants of Australia*). The gum is known as *Leopard tree gum*.

CEDAR GUM.—A light-yellow gum derived from the *Red cedar* or *Cedrella Australis* of Queensland. The tears swell and subsequently dissolve in water. It contains no resin, but of *arabin* 68 per cent, and of *metarabin* 6 per cent—(*P. J. Trans.*, 1890).

ACETA.—VINEGARS.

These are official liquid medicines, formed with vinegar as a menstruum and charged by maceration with different medicinal principles. Many medicines contain active principles which are not readily taken up by water or alcohol, or are, perhaps, insoluble in them, but which are freely soluble in vinegar; others again, although soluble in water or alcohol, are not as efficient and energetic thus prepared, as when tinctured in vinegar; on this account, *medicated vinegars* are especially useful in many instances. The vinegar of commerce is very apt to contain impurities and elements which lead to its decomposition; hence, when used as a solvent for pharmaceutical purposes, distilled vinegar or diluted acetic acid should be preferred. The solvent property of vinegar chiefly depends upon its acetic acid, which renders it more especially valuable in the preparation of those agents, especially alkaloids, which are soluble in this acid, or which are rendered more soluble by being converted into acetates. Medicated vinegars are not permanent preparations; and to prevent their spoiling too rapidly, a small proportion of alcohol is usually added to them, which, however, necessarily gives rise to some acetic ether, besides being sometimes liable to cause precipitation; if the same proportion of concentrated acetic acid be substituted for the alcohol, the formation of the ether may be avoided, and the medicated vinegar be preserved equally as well. It is better to prepare this class of compounds only as they are required.

ACETANILIDUM (U. S. P.)—ACETANILID.

FORMULA: $C_6H_5NH.C_2H_3O$. MOLECULAR WEIGHT: 134.73.

"An acetyl derivative of aniline"—(U. S. P.).

SYNONYMS: *Phenylacetamide*, *Antifebrin*, *Antifebrinum*, *Acetylamidobenzene*, *Acetanilide*.

Source and Preparation.—Acetanilid was first made in 1852 by Gerhard. It is prepared by heating to moderate ebullition equal quantities of glacial acetic acid and pure aniline. This should be accomplished in a retort or flask furnished with a reflux condenser, and the operation continued until a small amount of the mixture cools to a solid when taken from the flask. The resulting mass is then subjected to distillation, acetic acid and water first passing over, and lastly the acetanilid, which is subsequently crystallized by treating with boiling water. It is obtained white by subliming the crude acetanilid.

Description.—The Pharmacopœia describes this comparatively new drug as follows: "White, shining, micaceous, crystalline laminae, or a crystalline powder, odorless, having a faintly burning taste, and permanent in the air. Soluble, at 15° C. (59° F.), in 194 parts of water, and in 5 parts of alcohol; in 18 parts of boiling water, and in 0.4 part of boiling alcohol; also soluble in 18 parts of ether, and easily soluble in chloroform. When heated to 113° C. (235.4° F.), acetanilid melts. Upon ignition, it is consumed without leaving a residue. Acetanilid is neutral to litmus paper"—(U. S. P.).

It is also freely soluble in benzin, and sparingly so in disulphide of carbon.

Tests.—"When agitated with colorless, concentrated sulphuric acid, in a clean test-tube, acetanilid dissolves without imparting color to the liquid. On heating about 0.1 Gm. of acetanilid with a few Cc. of concentrated solution (1 in 4) of potassium or sodium hydrate, the characteristic odor of aniline becomes noticeable. On now adding chloroform, and again heating, the disagreeable odor of isonitril (which is poisonous) is evolved. On boiling 0.1 Gm. of acetanilid for several minutes with 2 Cc. of hydrochloric acid, a clear solution results which, when mixed with 3 Cc. of a 5 per cent aqueous solution of carbolic acid, and afterwards with 5 Cc. of a filtered, saturated solution of chlorinated lime (*Calx chlorata*), acquires a brownish-red color, becoming blue upon supersaturation with ammonia. A cold, saturated, aqueous solution of acetanilid, added to ferric chloride T.S., should not affect the color of the latter (absence of aniline salts and various allied substances)"—(U. S. P.).

Action, Medical Uses, and Dosage.—In health the effects of acetanilid are less pronounced than in febrile states. Small doses of acetanilid produce a quieting effect, and the renal and cutaneous secretions are augmented; blood-pressure

is first elevated, then depressed, and cardiac action is decreased in frequency. Moderate quantities act as a vaso-motor and cerebral stimulant. Large doses produce serious symptoms, powerfully depressing the nervous system and circulatory apparatus. Weakness, slight headache, tinnitus aurium, and general malaise, and often a sense of coldness, a peculiar cyanotic hue, collapse, convulsions, and death result from its immoderate use. Whether these symptoms are due to the patient's susceptibility or to impurities in the drug has not been definitely determined. It is claimed that the reduction of temperature when fever is present is due to its action in changing oxyhæmoglobin into methæmoglobin, and its consequent interference with oxidation, which produces the cyanosis. Very large doses increase the urea and uric acid in the urine, destroy the red corpuscles, decrease the alkalinity of the blood, and impart to the urine a deep-brown color, due to the liberation of hæmoglobin from the blood. When death is produced both motor and sensory paralysis ensues, and the heart is arrested in diastole. Among other symptoms noticed from varying doses of the drug are profuse perspiration, rubeoloid eruption, anæsthesia, coma, failing respiration, and loss of reflex action. Even 5 grains have been charged with causing collapse in one case and death in another. The drug is eliminated by the kidneys, and should be avoided in all cases of fatty degeneration, particularly of the heart, kidneys, and liver. Nausea, vomiting, and diarrhoea have been attributed to this drug by some, while others deny such effects.

Acetanilid was originally introduced as a remedy for *pyrexia*, and indeed by many its chief action is asserted to be antipyretic. It has, however, fallen into discredit in many quarters on account of the dangerous collapse and cyanotic condition which it often produces. It should have no place in fevers of a low or typhoid type, and we are admonished that while excellent results have been obtained in *scarlatina*, it should be carefully watched on account of the numerous instances of drug-intoxication observed from its use in children. Very little use is made of the drug by eclectic practitioners in febrile states, the exceptions, perhaps, being in *puerperal fever*, *rheumatic fever*, uncomplicated with cardiac disorders, and in *erysipelas*, in all cases to be used only when the temperature is excessively high. It may be used to control the *hætic fever of phthisis*. Acetanilid is of considerable value in *acute inflammatory rheumatism*, especially in those cases in which salicylic acid and the salicylates are said to be admissible, but fail to do any good. Here it contributes to reduce the swelling and alleviate the pain. It should not, however, be used in this complaint for any length of time, or in large doses. It is particularly useful when the rheumatic affection is ushered in with sharp and severe pain, in which case it should be preferred to opiates. Intense pain from muscular spasm is quickly relieved by it.

Acetanilid finds more favor with us in disorders of the nervous system than in any other class of affections. It is decidedly antispasmodic and analgesic. *Asthma*, *chorea*, some cases of *epilepsy*, *whooping cough*, and *bilious colic* seem to yield to its action, while in various *headaches* of a nervous origin it appears to be of considerable value. In *migraine*, *neuralgic* and *rheumatic headaches*, *sick headache*, *reflex headache*, from uterine disorders, *facial neuralgia*, *sciatica*, *neuralgias* depending on changes in the spinal cord, *neuralgia of tabes dorsalis*, and the pains of *locomotor ataxia*, its beneficial results are gratifying, and it has, in some cases, supplanted morphine in these affections as a pain-reliever. Indirectly, by relieving acute and subacute pain, it acts as a hypnotic, or rather prepares the way for a refreshing sleep. It should be borne in mind that it is a dangerous drug in fatty degenerations and in dilated states of the cardiac ventricles.

Locally, acetanilid has been recommended as a topical dressing for *chancre* and *chancroid*, and as an antiseptic for *wounds*. Here we have not found it of marked value. Dose: From 2 to 10 grains, in powder, capsule, or wafer, every 1 or 2 hours, until 3 doses have been taken; if used in febrile states, every 4 hours. We believe the small dose—even 1 grain—is as effectual as the larger doses when indicated. Great care should be exercised in its use. In cases of collapse, external heat, friction, alcoholic or ethereal stimulation, with sulphuric ether, strychnine, or atropine hypodermatically should be resorted to to sustain the breathing and circulatory organs.

Specific Indications and Uses.—Acute frontal and neuralgic headaches;

diffused headache of a nervous origin; congestive and reflex headaches when not due to gastric disorders or faulty digestion; sick headache; acute pain, with high temperature, provided the heart and kidneys are in good condition. The small dose preferred.

Related Drugs.—Various drugs are now upon the market which contain acetanilid in amounts reaching as high as 90 per cent. They are most generally antipyretics and analgesics, and figure largely as "headache cures." In some of them there has been detected sodium bicarbonate, caffeine salts, bromides, salicylic acid, and the salicylates. Some of these are now largely employed by the profession, and consequently should receive our attention.

ANTIKAMNIA.—This is a proprietary drug, whose definite composition is at present unknown to the profession. It is prepared by the Antikamnia Company, of St. Louis, Mo. Pharmacists have no legal right to make any substance under that name, and physicians can not employ any other than the genuine.

Antikamnia is a white powder. It also comes in tablet form. When dissolved in water, and in the presence of diluted acids, it effervesces. It is largely used as a substitute for morphine in painful states, particularly *rheumatism*, *neuralgia*, *nervous headache*, and *dysmenorrhœa*. Dose: 2½ to 5 grains. Larger doses have been recommended, but should be used with great care.

BENZANILID, *Benzanilide*, *Phenylbenzamid(e)*, *Benzoylanilide* ($C_6H_5.NH.C_6H_5.O$).—This compound is the result of the interaction of aniline, and benzoic anhydride, benzoyl chloride, or benzoic acid. It crystallizes in white, pearly scales, without taste or odor. It refuses to dissolve in water, is sparingly soluble in cold alcohol (1 in 58), and more freely in boiling alcohol (1 in 7). An eruption resembling measles has followed its use, and by continued use the medicine becomes less and less effective. The uses are much the same as for acetanilid, and the dose ranges from 1 to 12 grains.

BROMACETANILID, *Acetbromanilid* ($C_6H_4.BrNH.C_6H_5.O$).—The para-compound of this drug is known as *antiseptin*, and should not be confused with *antiseptin* and *antiseptol*. Neither should it be mistaken for *Ascepin*, a name which has (improperly) occasionally been applied to it. *Ascepin* can be applied properly only to the product known also as "*nascent wintergreen*." (See *Ascepin*.) *Antiseptin* is produced by acting upon acetanilid with bromine, and forms colorless crystalline needles, with neither taste nor odor. It fuses at about 165° C (329° F.). In water it is practically insoluble, sparingly soluble in glycerin, but more freely in alcohol and ether. Its chemical names are *mono-* or *paramono-bromphenylacetamide*, or *paramonobromacetanilid*. This drug is reputed antiseptic, antipyretic, and analgesic, and has been employed in *pneumonia*, *enteric fever*, *consumption*, and locally as a dressing for wounds and hemorrhoids. From ½ to 1 grain, three times a day is the usual dose.

METHYLACETANILID ($C_6H_5.NCH_3.C_6H_5.O$), *Ecalgin* or *Exalgine*.—This compound was first produced in 1874 by Mr. A. W. Hofmann. It may be prepared by slightly heating acetylchloride and monomethylaniline, and subsequent crystallization from boiling water. It may also be prepared by the interaction of sodium acetanilid and iodide of methyl. *Exalgine* forms small, acicular, or prismatic crystals, tasteless, odorless, and colorless. It dissolves readily in boiling water, chloroform, alcohol, and disulphide of carbon. It dissolves with difficulty in cold water (about 1 in 60 parts), and in about 1 in 10 of ether. It fuses in open air at about 100° C. (212° F.), but a couple of degrees lower when covered with water.

Its dose ranges from ½ grain to 5 grains (in diluted alcohol), though 3 grains three times a day is as high as is usually administered. It is employed for *neuralgias* and in *chorea*. It produces poisonous effects, among which are noted disturbed vision, tinnitus aurium, emesis, headache, spasmodic muscular action, jaundice, and cyanosis.

ANTINERVIN, *Salicyl-bromanilide*, *Salbromanilide*.—A proprietary drug, composed of bromoacetanilid and salicylanilid. According to Squibb, it is a mixture of ammonium bromide, and salicylic acid, of each one (1) part, and acetanilid two (2) parts. It has been recommended in *neuralgias* in doses of from 5 to 15 grains.

PHENOLID and **EXODYNE**.—Are compounds resembling antinervin in composition, the chief ingredient of which is thought to be acetanilid.

IODANTIFEBRIN, *Iodacetanilid* ($C_6H_4.INH.C_6H_5.O$).—Flake-like rhombic crystals, soluble in alcohol and glacial acetic acid, but scarcely soluble in water. Its physiological effects are slight, and it is not likely to prove of any value in therapy.

ACETONUM.—ACETONE.

FORMULA: C_3H_6O . **MOLECULAR WEIGHT:** 57.87.

SYNONYMS: *Pyroacetic ether*, *Pyroacetic spirit*, *Acetyl-methylide*, *Di-methyl-Ketone*, *Ether pyroaceticus*, *Spiritus pyroaceticus*.

History and Preparation.—This substance is prepared by the dry distillation of the acetates, and other substances, such as tartaric and citric acids, and from sugar and various other carbohydrates. It is produced in large quantities as a by-product in the making of aniline. To obtain it, either barium-, lead-(4 parts with 1 of burnt lime), or calcium acetate (usually one of the latter two), is subjected to dry distillation in an earthenware retort, and treated fractionally with

calcium chloride to free it from H_2O . Acetone exists in small quantities in the blood, urine, and abundantly in diabetic urine. It is asserted that the odor peculiar to persons suffering from diabetes is due to the exhalation of acetone. To this substance is charged the pulmonary complications and coma in the latter stage of this disease. It is extensively used in the manufacture of chloroform, both in the United States and abroad. For this purpose it is distilled with calcium hypochlorite and water. It is converted into iodoform when acted upon by iodine in the presence of an alkali.

Description.—Boil. pt. $58^{\circ} C$ ($136^{\circ} F.$); sp. gr. 0.7921 at $18^{\circ} C$ ($64.4^{\circ} F.$). Acetone is a limpid, colorless liquid, readily inflammable, burning with a clear, luminous flame. It is miscible with water, ether, alcohol, and volatile oils in all proportions. Its odor is agreeable, ethereal or mint-like, and its taste sharp, burning, and sweetish. It is principally valued for its property of dissolving fats, resins, gun-cotton, and camphors.

J. U. Lloyd has shown that of all the ordinary neutral solvents, acetone stands conspicuous, in that equal bulks of others capable of mixing with any proportion of water form a transparent mixture with all proportions of glycerin, while equal bulks of acetone and glycerin separate the larger share of the glycerin. Prof. Henry Trimble has shown that acetone is the best solvent for tannins, and that it may be used in many manufacturing processes. His predictions are likely to be verified in commerce.

Action, Medical Uses, and Dosage.—Acetone is soporific, intoxicating, and anthelmintic. From 15 to 20-drop doses, administered in sweet spirit of nitre, are recommended in *gout* and *rheumatic complaints*, and for the expulsion of *worms* from the intestinal tract. It was formerly employed to check the secretions and *cough* of pulmonary complaints. It is of but little use as a medicine.

Related Compounds.—**ACETAL**, *Di-ethyl-Acetal* ($C_6H_{14}O_2$, or $CH_3CH[C_2H_5O]_2$).—Molecular Weight, 117.74. Sp. gr. 831 at $20^{\circ} C$ ($68^{\circ} F.$); boil. pt. $104^{\circ} C$ ($219.2^{\circ} F.$). A colorless liquid, produced by the oxidation of alcohol through the agency of sulphuric acid and manganese dioxide, and other means. Acetal has an agreeable odor, somewhat like alcohol, and a persistent, pungent, yet refreshing, taste. It is slightly soluble in water, but dissolves freely in alcohol or ether. It must be preserved from the atmosphere and oxidizers, which change it to aldehyde, resulting finally in the formation of acetic acid.

Acetal acts upon the brain, slowly intoxicating even to insensibility. It lowers blood-pressure, thereby acting as a hypnotic. Its hypnotic effects are followed by depression, heavy sensations in the extremities, and nausea. It kills by asphyxiation. It is but little used. Its hypnotic dose is from 1 to 3 drachms.

ACETOPHENONE, *Phenylmethyl-ketone* ($C_8H_8.CO.CH_3$), *Hypnone*.—This product was prepared in 1857 by Friedel, who obtained it by dry distillation of a mixture of acetate and benzoate of calcium. It was introduced in medicine by Dujardin-Beaumez as *hypnone*. It is now prepared by the interaction of benzoyl chloride and zinc-methyl. It may be obtained in white plate-like crystals, but the form generally employed is *liquid hypnone*. The latter is a highly refrangent, mobile liquid, pungent and disagreeable to the taste, and possessing a mixed odor of orange and bitter almonds, which is persistent. Though non-inflammable, it adds to the inflammability of substances saturated with it. Hypnone refuses to dissolve in water, remaining therein suspended as globules. It dissolves sparingly in glycerin and freely in alcohol, chloroform, ether, benzol, and the fixed oils. It dissolves iodine and bromine with ease, and when treated with chromic acid is resolved into carbon dioxide and benzoic acid. Its density is 1.032. It becomes solid at $14^{\circ} C$ ($57.2^{\circ} F.$), and fuses again at $20.5^{\circ} C$ ($68^{\circ} F.$). A convenient form of administration is in emulsion with peppermint water or syrup, or in oleaginous solution, given in capsules. A syrup may be prepared with 1 drop of hypnone, 16 drops of alcohol, and 100 drops of syrup of orange; an elixir with 1 drop of hypnone and 50 drops each of alcohol and peppermint syrup. It is regarded as a hypnotic, possessing, in rather large doses (6 to 8 drops), a slight anodyne action. There are several objections to its use, chief among which are its tendency to produce gastric disturbance, its unpleasant taste, and the disagreeably persistent odor it imparts to the breath, besides being dangerously depressant. It is not a reliable drug for pain, nor can much be expected of it when insomnia is occasioned by nervous excitation.

ACETUM.—VINEGAR.

SYNONYMS: *Acetum britannicum* (British malt vinegar), *Acetum gallicum* (French wine vinegar), *Acetum destillatum* (distilled vinegar), *Acetum crudum*.

Source and History.—Vinegar is a dilute acetic acid, combined with foreign coloring and flavoring substances, and is prepared by the acetification of cider, malt, or wine, and by the oxidation of alcohol. It is the result of a fermentative

process, known as the *acetous*, by which certain liquids or infusions undergo a change, causing them to have a manifest sourness to the taste. Those fluids which are capable of acetous fermentation possess more or less saccharine matter, as fruits, grain, etc. In order to effect an acetous fermentation a temperature is required, ranging from 21° to 35° C. (70° to 95° F.), which is accompanied with the formation of a remarkable vegetable, of a fungous and microscopic character, consisting of the mycelium of *Penicillium glaucum*, vegetating actively, and increasing by crops of *conidia* or *gemmæ*. By some this vinegar-plant has been named *Torula aceti*. During this process the alcohol of the previous vinous fermentation disappears, and its place is occupied by vinegar. According to Pasteur, this microscopic vegetation is the *Mycoderma aceti* (*Ulvina aceti*, Kützing), and that it is this agent and not the atmospheric oxidation that gives rise to the process of acetification.

Preparation and Description.—Vinegar is prepared from many substances. In France red wines are principally employed; in Britain it is made from different kinds of malt liquor, cider, saccharine fluids, etc.; and in the United States from cider and whiskey chiefly. The Germans have a quick method of making vinegar, by mixing certain proportions of alcohol, water, and honey, extract of malt or ferment, and which, by a certain process is exposed to the atmosphere by distributing it over beech-wood shavings in a large vat, that it may have an extensive surface for oxidation, and is thereby converted into vinegar in from 24 to 36 hours. Vinegar is likewise made by several other processes, some of which require a comparatively short time for its formation. The surface of vinegar is frequently covered by moldiness (*Mucor mucedo*); a small fly (*Musca cellaris*) is apt to infest it; microscopic animals, called vinegar eels (*Anguillula aceti*) are common to vinegar containing mucilage and no sulphuric acid; and, on long standing, or when kept in open vessels, a gelatinous, vegetable substance, called the "mother of vinegar" (*Mycoderma cerevisiæ*), is formed at the expense of the acid, rendering the vinegar turbid and weaker. These matters may be removed by boiling the vinegar, and then filtering it.

Good vinegar has a peculiar and grateful odor, and an agreeable sour taste. Its color depends somewhat on its mode of manufacture; when prepared from malt liquors it is yellowish-red; when from wine it is pale or deep-red, depending upon the white or red wine from which it is made; and when from cider it is pale-yellow. The high-colored vinegars may be rendered colorless by filtration through charcoal, or by distillation in a glass retort.

Adulterations and their Detection.—Crude vinegar contains a small amount of sulphates and chlorides. Consequently barium chloride, which precipitates the sulphates, is not a good testing reagent to detect free sulphuric acid in vinegar, but upon boiling the latter with calcium chloride a precipitate will show the presence of free acid, but not sulphates, in small amounts. When vinegar is free from sulphuric acid, acetate of lead has no action upon it. Copper may be detected by the addition of ammonia in excess, which renders the vinegar blue, nor should metallic copper be deposited on a clean, bright piece of iron immersed in it. Vinegar containing lead gives a yellow precipitate of iodide of lead, when iodide of potassium is added to it; when it is free from lead and copper, hydrogen sulphide causes no precipitate. When the mineral acids are present they may be detected, according to Chiappe, by producing a deep-blue coloration, with an aqueous or alcoholic solution of Paris violet (methyl-anilin-violet).

Action, Medical Uses, and Dosage.—Vinegar forms an agreeable cooling drink in *fevers*, especially when the tongue is red and coated dark or brown; it diminishes inordinate vascular action, allays thirst, neutralizes excess of alkali, and increases the urinary discharge. In *typhus*, *scurvy*, and *putrid diseases* it acts as an antiseptic. In *urinary affections*, attended with a white sediment consisting mainly of phosphate of calcium and ammoniaco-magnesian phosphate, it has been recommended. In *dysentery* and *scarlatina*, vinegar, saturated with common house-salt, has been very beneficial. A large tablespoonful of the mixture must be added to 4 of hot water, of which a tablespoonful is to be taken, as hot as may be, every 2 or 3 minutes, till the whole is consumed. A similar preparation proved very effectual in the treatment of *Asiatic cholera* in Cincinnati during 1849-50, and has likewise been found beneficial as a local application in

external inflammations, contusions, severe injuries to joints, swellings, etc. The vapor of vinegar, inspired with that from hot water from a proper inhaler, is of decided service in most varieties of laryngeal inflammation, tonsillitis, hoarseness, putrid sore throat, diphtheria, relaxed sore throat, and ulceration of the fauces; this inhalation will also be found of great utility in dryness and irritation of the pulmonary tubes during measles and other exanthematous diseases. Diluted, it is a favorite domestic remedy for fumigating the apartments of those ill of contagious diseases; it does not destroy the infection, but renders the atmosphere less disagreeable. Vinegar has been used as a gargle in the same affections of the throat and fauces. It has also been applied locally in some cases of ophthalmia, in epistaxis, several cutaneous diseases, and diluted with water has been used as an injection into the rectum in hemorrhoidal affections, and into the uterus in cases of uterine hemorrhage. Injected into the rectum it destroys ascarides, and as a lotion is said to be fatal to pediculi. Large doses of vinegar induce diarrhoea and impair digestion; small doses, however, favor digestion by stimulating the gastric and salivary secretions and aid in softening otherwise indigestible food. Vinegar is one of the best antidotes to poisoning with the caustic alkalis, as it is always at hand. It is also valuable, in weak dilution, to assist in removing particles of lime from the eye. It forms a valuable adjuvant to cooling lotions. The dose internally is from 1 to 4 fluid drachms; as an injection, 1 or 2 fluid ounces, diluted with twice or thrice its bulk of water (see *Acetum Destillatum*).

Specific Indications and Uses.—The deep-red tongue, with dark or brown coating.

Vinegar Preparations.—*ACETUM DESTILLATUM*, *Distilled vinegar*, *Acetum purum*.

PREPARATION AND DESCRIPTION.—Take of vinegar 8 parts, place in a glass or silver retort, and distill over into a receiver of similar material 7 parts. Dilute the product, if necessary, with distilled water, till the specific gravity is 1.006.

Distilled vinegar is recommended to be prepared from wine vinegar, chiefly on account of its aroma; and it should be prepared in glass or silver vessels, as lead or copper ones are extremely dangerous from the poisonous salts liable to be formed, viz.: the acetate of lead or copper. It is a clear liquid, occasionally with a yellowish tint, and differs from dilute acetic acid in containing a small proportion of alcohol, acetic ether, and mucilage. Excess of alkali added to it, and the solution heated, gives a brown color to the liquor, with a dark precipitate, which is supposed to be the decomposed mucilage. When of good quality distilled vinegar is quite colorless, of a pure acetous odor, frequently somewhat ethereal, but entirely unmixed with empyreuma or other disagreeable taint, and is wholly evaporated by heat. It is rendered unfit for pharmaceutical purposes by the presence of metals or mineral acids.

Distilled vinegar is used for the same purposes as above, and is the solvent to be employed in making the various medicated vinegars of opium, squill, colchicum, etc. Care must be taken, when using vinegar medicinally, not to obtain the spurious and adulterated articles, containing sulphuric acid, hydrochloric acid, nitric acid, copper, lead, etc. One part of acetic acid to 5 of distilled water forms a very good vinegar for culinary and medicinal purposes.

ACETUM AROMATICUM, *Aromatic vinegar*.—Several aromatic vinegars have appeared in various pharmacopœias, some directing the use of oils to give the aromatic qualities, as in the formula of the *German Pharmacopœia*, and others directing the tinctures of the aromatic herbs, as in the *French Codex*. The following formula corresponds to that of the *German Pharmacopœia*: Take 1 part each of the essential oils of cinnamon (Cassia), juniper, rosemary, peppermint, and lavender; 2 parts each of oils of cloves and lemon; 450 parts of alcohol; 650 parts of acetic acid, and 1900 parts of water. An alcoholic solution of the oils is first prepared, the acid, and afterward the water, added, and the whole allowed to stand (with frequent shaking) 8 days, after which it is filtered. This gives a colorless, clear preparation, which will mix, without turbidity, with any amount of water. It has an acetous, aromatic odor. The *National Formulary* gives the following:

ACETUM AROMATICUM (N. F.), *Aromatic vinegar*.—*Formulary number*, 1: "Oil of lavender, $\frac{1}{2}$ cubic centimeter (0.5 Cc.) [8 $\text{m}\bar{\text{p}}$]; oil of rosemary, $\frac{1}{2}$ cubic centimeter (0.5 Cc.) [8 $\text{m}\bar{\text{p}}$]; oil of juniper, $\frac{1}{2}$ cubic centimeter (0.5 Cc.) [8 $\text{m}\bar{\text{p}}$]; oil of peppermint, $\frac{1}{2}$ cubic centimeter (0.5 Cc.) [8 $\text{m}\bar{\text{p}}$]; oil of cinnamon (Cassia), $\frac{1}{2}$ cubic centimeter (0.5 Cc.) [8 $\text{m}\bar{\text{p}}$]; oil of lemon, 1 cubic centimeter (1 Cc.) [16 $\text{m}\bar{\text{p}}$]; oil of cloves, 1 cubic centimeter (1 Cc.) [16 $\text{m}\bar{\text{p}}$]; alcohol, 175 cubic centimeters (175 Cc.) [5 fl $\bar{\text{z}}$, 440 $\text{m}\bar{\text{p}}$]; acetic acid (U. S. P.), 175 cubic centimeters (175 Cc.) [5 fl $\bar{\text{z}}$, 440 $\text{m}\bar{\text{p}}$]; water, a sufficient quantity to make 1000 cubic centimeters (1000 Cc.) [33 fl $\bar{\text{z}}$, 391 $\text{m}\bar{\text{p}}$].

Dissolve the oils in the alcohol, add the acetic acid, and lastly, enough water to make one thousand (1000) cubic centimeters [33 fl $\bar{\text{z}}$, 391 $\text{m}\bar{\text{p}}$]. Warm the turbid mixture, during several hours, at a temperature not exceeding 70° C. (158° F.), taking care that it shall not suffer loss by evaporation. Then set it aside for a few days, occasionally agitating, and filter"—(*Nat. Form.*).

ACETUM ANTISEPTICUM, *Antiseptic vinegar*.—The *French Codex* directs an antiseptic vinegar prepared as follows: Take 15 parts each of Roman wormwood, rosemary, peppermint, sage,

rue, lavender, and absinth; 2 parts each of nutmeg, cloves, cinnamon, garlic, and calamus; 1000 parts of vinegar. Macerate the whole 10 days, and after expressing, add 4 parts of camphor dissolved in 15 parts of glacial acetic acid. Filter.

ACETUM CANTHARIDIS.—VINEGAR OF CANTHARIDES.

Preparation.—Take bruised cantharides, 2 ounces; glacial acetic acid, 2 fluid ounces, and a sufficient quantity of acetic acid to make 20 fluid ounces. Mix with the glacial acetic acid 13 fluid ounces of acetic acid; add the cantharides and digest for a couple of hours at a temperature of 93.3° C. (200° F.). After the mixture has cooled, transfer it to a percolator, and when the fluid has ceased to pass add to the residue 5 fluid ounces of acetic acid. After completion of the percolation, press the residue, filter the fluid so obtained, and mix it with the percolate. Finally, by the addition of acetic acid bring the product to measure 1 pint (Imp.). This agrees with the *British Pharmacopœia*.

Action and Medical Uses.—This preparation is a speedy blistering agent. Applied to the skin lightly it acts as a rubefacient. But if applied in successive layers with a soft brush, vesication results in from one to three hours. It is convenient to apply to uneven surfaces where vesicating plasters are less likely to remain in contact. After application the blister should be dressed with simple ointment applied on cotton-wool, or soft linen. It is a painful application, and has been recommended for vesicating small areas in *superficial neuralgias* and *rheumatic parts*.

ACETUM IPECACUANHÆ.—VINEGAR OF IPECACUANHA.

Preparation.—Ipecacuanha (No. 20 powder), 1 ounce (av.); diluted acetic acid, q.s. for 20 fluid ounces (Imp.). After moistening the drug with a sufficient amount of the acid, macerate 24 hours, then pack the moistened powder in a percolator, and gradually add the diluted acid until 20 fluid ounces (Imp.) are obtained.

Description, Uses, and Dosage.—The foregoing process is in accordance with that of the *British Pharmacopœia*, and yields a yellow-brown preparation retaining permanently the emetic constituents in solution. A feeble, cutaneous irritant and expectorant. The uses are those of *Ipecacuanha*, which see. The dose ranges from 5 to 40 minims.

ACETUM LOBELIÆ.—VINEGAR OF LOBELIA.

Preparation.—Take of lobelia seed, in powder, 4 ounces; diluted acetic acid, 2 pints. Macerate the lobelia seed with the diluted acetic acid, in a close glass vessel, for 7 days; then express the liquor, filter, and add to the filtered product, alcohol (or concentrated acetic acid), 1 fluid ounce. The whole amount of fluid thus procured should measure 2 pints. This medicated vinegar may also be prepared by percolation.

History.—In this old eclectic preparation the alcohol is added to impede the decomposition, and as its quantity is very small, no objection can reasonably be made to its presence. We have known this preparation to retain its activity for two years, when kept well corked and not exposed to the action of light. We use lobelia seed instead of the herb, as employed in the *National Formulary* (see *Related Preparation*).

Action, Medical Uses, and Dosage.—Vinegar of lobelia is an emetic, nauseant, and expectorant, and is a valuable relaxant, in *spasmodic affections*, especially in *spasmodic and congestive disorders of the respiratory tract*. It may be given to fulfil all the indications for which lobelia is administered. Externally, it forms an excellent application in several *cutaneous diseases*, as *salt-rheum*, *erysipelas*, *poisoning by rhus*, etc. Dose, as an emetic, from 1 to 4 fluid drachms, repeated every 15 minutes; as an expectorant, from 5 to 30 drops or more, every half-hour, in elm or flax-seed infusion. One part of vinegar of lobelia added to 1 part, by measure, of syrup, forms a very pleasant preparation for children.

Related Preparation.—ACETUM LOBELIÆ (N. F.). (U. S. P., 1880). *Vinegar of lobelia.* *Formulary number, 2:* "Lobelia, in No. 30 powder, 100 grammes (100 Gm.) [3 oz. av. 231 grs.]; diluted acetic acid (U. S. P.), a sufficient quantity to make 1000 cubic centimeters (1000 Cc.) [33 fl̄, 391 ℥]. Moisten the powder with fifty (50) cubic centimeters [1 fl̄, 331.5 ℥] of diluted acetic acid, pack it firmly in a conical glass percolator, and gradually pour diluted acetic acid upon it until one thousand (1000) cubic centimeters [33 fl̄, 391 ℥] of percolate are obtained"—(Nat. Form.).

ACETUM OPII (U. S. P.)—VINEGAR OF OPIUM.

SYNONYM: *Black drop.*

Preparation.—"Powdered opium, 100 grammes (100 Gm.) [3 oz. av., 231 grs.]; nutmeg, in No. 80 powder, 30 grammes (30 Gm.) [1 oz. av., 25.5 grs.]; sugar, 200 grammes (200 Gm.) [7 oz. av., 24 grs.]; diluted acetic acid, a sufficient quantity to make 1000 cubic centimeters (1000 Cc.) [33 fl̄, 391 ℥]. Macerate the opium and nutmeg in five hundred (500) cubic centimeters [16 fl̄, 435 ℥] of diluted acetic acid during 7 days, frequently stirring; then strain through muslin of close texture, and express the liquid. Mix the residue with two hundred (200) cubic centimeters [6 fl̄, 366 ℥] of diluted acetic acid to a uniform magma, and strain and express again. Mix and filter the strained liquids, dissolve the sugar in the filtrate, and pass enough diluted acetic acid through the filter to make the product measure one thousand (1000) cubic centimeters [33 fl̄, 391 ℥]"—(U. S. P.).

Assay.—"To assay this preparation, transfer 100 Cc. of it to a small capsule, add 4 Gm. of precipitated calcium carbonate, or such a quantity as will be sufficient to neutralize the free acid, and then proceed further as directed under *Tinctura Opii*. It should yield from 1.3 to 1.5 Gm. of crystallized morphine"—(U. S. P.).

Description and Dosage.—This preparation, unfortunately known as *black drop*, now contains 10 per cent of opium, the latter containing from 13 to 15 per cent of crystallizable morphine. It is a dark-brown-red liquid, almost free from the disagreeable taste and odor of tincture of opium and less liable to nauseate the patient. The name *black drop* should be discarded on account of its liability to confusion with *black draught*. The dose is from 5 to 10 drops.

ACETUM SANGUINARIÆ.—VINEGAR OF BLOODROOT.

Preparation.—Take of bloodroot, in powder, 4 ounces; diluted acetic acid, 2 pints. Macerate the bloodroot with the diluted acetic acid in a close glass vessel for 7 days; then express the liquor, filter, and add to the filtered product, alcohol (or concentrated acetic acid), 1 fluid ounce. The whole amount of fluid thus procured should measure 2 pints. This medicated vinegar may also be prepared by percolation.

History.—In this preparation diluted acetic acid is used instead of distilled vinegar. When kept well corked and in the dark, it may be preserved for a long time, though it loses its dark-red color. It is an old eclectic remedy, but a formula is now to be found in the *National Formulary* (see *Related Preparation*).

Action, Medical Uses, and Dosage.—Vinegar of bloodroot is seldom used as an emetic, except in combination with other agents of this class. Its chief employment internally is as an expectorant, hepatic, and alterative. As an external application it is useful in many *cutaneous affections*. Dose, from 10 to 30 drops, in some mucilage or syrup, and repeated 3 or 4 times a day.

Related Preparation.—ACETUM SANGUINARIÆ (N. F.). (U. S. P., 1880). *Vinegar of sanguinaria.* *Formulary number, 3:* "Sanguinaria, in No. 30 powder, 100 grammes (100 Gm.) [3 oz. av., 231 grs.]; diluted acetic acid (U. S. P.), a sufficient quantity to make 1000 cubic centimeters (1000 Cc.) [33 fl̄, 391 ℥]. Moisten the powder with fifty (50) cubic centimeters [1 fl̄, 332 ℥] of diluted acetic acid, pack it firmly in a conical glass percolator, and gradually pour diluted acetic acid upon it until one thousand (1000) cubic centimeters [33 fl̄, 391 ℥] of percolate are obtained"—(Nat. Form.).

ACETUM SCILLÆ (U. S. P.)—VINEGAR OF SQUILL.

Preparation.—"Squill, in No. 30 powder, 100 grammes (100 Gm.) [3 oz. av., 231 grs.]; diluted acetic acid, a sufficient quantity to make 1000 cubic centimeters (1000 Cc.) [33 fl̄, 391 ℥]. Macerate the squill with nine hundred (900)

cubic centimeters [30 fl3, 208 M] of diluted acetic acid during 7 days, frequently stirring; then strain through muslin, and wash the mass on the strainer with enough diluted acetic acid, until the strained liquid measures one thousand (1000) cubic centimeters [33 fl3, 391 M]. Finally filter"—(U. S. P.).

Action, Medical Uses, and Dosage.—Vinegar of squill contains all the medicinal virtues of the squill. It is a clear, yellowish fluid, of a bitter acid taste, and possessing an acetous smell. It is sometimes employed as an expectorant in affections of the air vessels, and as a diuretic in *dropsies* caused by cardiac disease; but, on account of its tendency to decomposition, its principal use is in the preparation of syrup of squill. This preparation represents 10 per cent of squill. Its dose is from 15 to 60 minims, in some aromatic water.

ACHILLEA.—YARROW.

The whole plant, *Achillea Millefolium*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES.—Yarrow, Milfoil, Thousand leaf.

ILLUSTRATION: Bentley and Trimen., *Med. Plants*, 153; Woodville, *Med. Bot.*, 15.

Botanical Source and Description.—Yarrow is a common perennial plant from 1 to 3 feet in height, bearing dark-green, crowded, alternate, bi-pinnatifid leaves. The flowers, which are grayish-white (occasionally rose-colored), are arranged in a flat-top, corymbose head. The odor is peculiar, being pleasantly and highly aromatic, somewhat resembling chamomile. The taste is sharp, bitterish, astringent, and slightly saline.

History.—Yarrow is a common wayside herb, and is also found growing wild in fields, pastures, and waste places throughout the central portions of North America and Europe. It flowers from May to October, during which time it should be gathered (preferably during July), and after rejecting the coarser stems, should be carefully dried. The weight, after drying, is but 15 per cent of the amount collected. The leaves are more astringent than the flowers, the latter being more aromatic than the former. The American plant is said to be more valuable than the European species. *Achillea* was known to the ancients. Pliny states that the generic term, *Achillea*, was named from Achilles, a physician, who was one of the first to use a species of this plant as a vulnerary. Yarrow is sold by the native herbalists of India, like rosemary, where it is used as a bitter and in medicated vapor baths for fevers (Dymock). The Italians employed it in intermittent fevers, and in the Scottish highlands it is made into ointment for wounds. According to Linnæus the Dalecarlians used it as a substitute for hops in the making of ale, believing it to impart to it intoxicating qualities. Both Stahl and Haller used this plant extensively.

Chemical Composition.—Yarrow contains a reddish-brown, active, bitter principle called *achillein* ($C_{20}H_{28}N_2O_{10}$), discovered by Zanon, in 1846 (Liebig's *Annalen*), and shown by Von Planta (1870) to be alkaloidal and identical with the *achilleine* of *Achillea moschata*. Zanon also found an acid which he named *achilleic acid*, and which was subsequently (1857) shown by Hlasiwetz to be *aconitic acid*. A small portion of a volatile oil, dark-green in color, may be obtained from yarrow by distillation with water. Milfoil also contains potassium and calcium salts, resin, gum, and tannin.

Action, Medical Uses, and Dosage.—Yarrow possesses slightly astringent properties, and is tonic, alterative and diuretic, in infusion. Its use in *chronic diseases of the urinary apparatus*, is especially recommended by Prof. J. M. Scudder. It exerts a tonic influence upon the venous system, as well as upon mucous membranes. It has been efficacious in *sore throat*, *hemoptysis*, *hematuria* and other forms of *hemorrhage* where the bleeding is small in amount, *incontinence of urine*, *diabetes*, *hemorrhoids* with bloody or mucoid discharges, and *dysentery*; also in

Fig. 1.

Achillea.

amenorrhœa, *flatulency* and *spasmodic diseases*, and in the form of injection in *leucorrhœa* with relaxed vaginal walls. Prof. T. V. Morrow made much use of an infusion of this herb in *dysentery*. Given in half-drachm doses of the saturated tincture, or 20-drop doses of specific achillea, it will be found one of our best agents for the relief of *menorrhagia*.

The active principle, *Achillein*, has been employed in France and other portions of Southern Europe, as a substitute for quinine in the treatment of *intermittent fevers*. It has also been employed by French physicians to restore *arrested lochial discharges*.

Of infusion (3i to Aqua Oj), 1 to 2 fluid ounces; specific achillea, 5 to 30 drops; volatile oil, 5 to 20 drops. All preparations of achillea are rendered more pleasant to the taste by the addition of a few drops of oil of anise.

Specific Indications and Uses.—To relieve urinary irritation, strangury, urinary suppression; relieves irritation in incipient Bright's disease, capillary relaxation, leucorrhœa with relaxed and irritated vaginal walls, hematuria, gastric and intestinal atony, atonic amenorrhœa, menorrhagia.

Related Species.—*Achillea Ptarmica*, Linné. *Sneezewort*. Naturalized in the Eastern States, growing in hedges, thickets, and moist places. The leaves are remarkably distinct from those of yarrow, being lance-linear, sessile, acuminate and serrate. The flowers are white and arranged in a diffuse corymb. Sialagogue and sternutatory.

Achillea moschata, Linné. *Iva*, *Musk milfoil*. An Alpine plant having the odor of musk, largely used by the Swiss as a sudorific and for its healing qualities. It contains *isoal* ($C_{15}H_{20}O$), a bluish-green or azure, bitterish, mintlike, volatile oil (called *Esprit d'Iva*, at Engadine, where it is extracted); *moschatine* ($C_{21}H_{27}NO_7$), a nitrogenous body; an alkaloidal principle, *achilleine* ($C_{20}H_{25}N_3O_{11}$); and *isoin* ($C_{21}H_{27}O_3$), a yellow, soft bitter, soluble in alcohol. Upon boiling with dilute acids, achilleine yields, besides sugar, ammonia, and an odoriferous principle, *achilleine* ($C_{11}H_{17}NO_4$), a non-bitter, insoluble, deep-brown body.

Achillea ageratum, Linné. *Europe*. This species has tufted, clammy leaves and a disagreeable odor and bitter taste. Used occasionally as a medicine.

Achillea nobilis, Linné. *Europe*. This pubescent species has a stronger taste and odor than common milfoil, and is sometimes used for similar purposes. The *Achillea nana*, Linné, and *Achillea atrata*, Linné, both natives of Europe, are likewise employed medicinally, the latter especially for its stimulating effects in the early stages of fevers.

ACIDUM ACETICUM (U. S. P.)—ACETIC ACID.

FORMULA: $HC_2H_3O_2 = C_2H_5O.OH = CH_3.CO_2H$. **MOLECULAR WEIGHT:** 59.86.

"A liquid composed of 36 per cent, by weight, of absolute acetic acid [$HC_2H_3O_2$, = 59.86] and 64 per cent of water"—(U. S. P.).

SYNONYMS: *Acetyl hydrate*, *Hydrogen acetate*.

Source.—Acetic acid is the most extensively used organic acid, and is obtained either by the oxidation of alcohol and aldehyde, or by the destructive distillation of wood and carbohydrates in general. This yields an impure pyroligneous vinegar, which is subsequently purified. The greater portion of the acetic acid of commerce is now derived from this wood vinegar. As early as 1648 Glauber was familiar with the fact that vinegar could be obtained by the destructive distillation of vegetable tissues, but did not know that the substance so obtained was identical with the vinegar derived from alcoholic products. This identity was subsequently established (1800) by Vauquelin and Fourcroy. In 1802 Thénard proved its existence in products of dry distillation of animal tissues. Stahl proposed in 1700 a method to obtain acetic acid from vinegar by exposing the latter substance to a freezing temperature, separating the ice from the stronger acid; another method he suggested was to neutralize with an alkali and to evaporate, then distilling with an equal amount of sulphuric acid. In 1759 Count de Lauragnais obtained a crystallized acetic acid in a distillate of cuprum acetate, then known as "*copper spirit*." The name *glacial acetic acid* was affixed to this substance by Löwitz (1793), who repeatedly distilled diluted acetic acid with powdered charcoal, and obtained thereby a crystalline acid by subjecting the product to a low temperature.

Preparation and Description.—In order to bring before the reader the processes of the production of acetic acid it will be necessary to allude to the production of crude pyroligneous acid by the destructive distillation of woody sub-

stances. We shall then present the three commercial forms of acetic acid now in common use, viz.: acetic acid, glacial acetic acid, and diluted acetic acid.

I. ACIDUM ACETICUM PYROLIGNOSUM. *Acidum pyrolignosum. Pyroligneous acid, Pyroligneous vinegar.*

Preparation.—Crude pyroligneous acid is one of the principal products formed in the destructive or dry distillation of wood; i. e., in the process of subjecting the wood to a red heat in a closed vessel, so that the air has no access. This is done at present in closed iron retorts, much on the same plan as the destructive distillation of coal is carried on in the manufacture of illuminating gas. The vapors are condensed in suitable vessels, and the incondensable, gaseous products frequently conducted back into the furnace. The liquid obtained separates upon standing into two layers—an upper, aqueous, and a lower, tarry layer, the latter furnishing the material from which creosote is obtained by rectification. It contains benzene and its homologues, naphthalene, retene, phenol, cresol, phlorol, pyrocatechol, guaiacol and homologues, and empyreumatic substances. The upper stratum is the crude pyroligneous acid of commerce, and is separated by mechanical processes. It contains in aqueous solution formic and acetic acids and their homologues, including capronic acid, methyl alcohol, acetone, acetates of methylamine, phenol, guaiacol, furfural, and empyreumatic substances. From this liquid are obtained commercially: Acetic acid, acetone, and methyl alcohol. The first step of separation is that of fractional distillation of the crude pyroligneous acid. The first part coming over (10 per cent) is the alcoholic part, called *wood naphtha*, and consists of methyl alcohol, acetone, and methyl acetate, also containing allylic and other alcohols; then distills the acid part, called *purified pyroligneous acid* or *rectified wood vinegar*, amounting to 75 to 80 per cent. It is a yellowish or colorless acid fluid, possessing a smoky odor, which may be removed by agitating it with 2 or 3 per cent of benzin, and removing the latter by separation and distillation; then the aqueous residue will furnish an inferior table vinegar. The preparation of pure acetic acid from rectified wood vinegar will be described under "Acetic Acid." As to the quantities obtainable, 100 parts of wood yield from 20 to 35 per cent of gas, 8 to 9 per cent of tar, 35 to 45 per cent of crude pyroligneous acid, of which 8 to 9 per cent are acetic acid, and 20 to 30 per cent of charcoal. It has been found that the percentage of real acetic acid obtainable from diverse woods varies considerably; the bark yielding less than the wood, sound wood more than decayed wood, and stem woods yielding the greatest quantity, even more than the branch woods; foliage trees produce a greater yield of pure acid than needle-leaved species. Slow combustion is also conducive to a better yield. The average yield of acid liquor from 800 pounds of wood is about 300 pounds, or 35 gallons.

Description.—Crude pyroligneous acid is a dark-brown, sour liquid, of a smoky odor (due to furfural $[C_4H_4O_2]$, Meyer), holding in aqueous solution 4 to 7 per cent of acetic acid, empyreumatic oil, creosote, and pyroxylic spirit.

II. ACIDUM ACETICUM GLACIALE (U. S. P.). *Glacial acetic acid; Radical vinegar.*

Preparation.—Pure sodium acetate ($13\frac{1}{2}$ parts), in crystals, is carefully heated until the water of crystallization is completely driven off and the salt fused. The residue (nearly $8\frac{1}{2}$ parts by weight) is then reduced to a coarse powder and transferred to a retort. The retort is then carefully warmed in a sand-bath; and to the contained salt is added from $9\frac{1}{2}$ to 10 parts by weight of strong sulphuric acid and intimately mixed. It is then distilled. The product, though containing some water, is glacial acetic acid. It may be obtained nearly free from water by distilling a portion and then pouring off the liquid, and finishing the distillation by repeating the operation.

Description.—Glacial acetic acid is the strongest preparation of acetic acid, and is so named on account of its ice-like appearance when crystallized. According to both the British and United States Pharmacopœias, it should contain at least 99 per cent of absolute acid. Below $15.5^{\circ} C.$ ($60^{\circ} F.$) it forms flat, colorless, ice-like, rhombic crystals. If heated above this point it changes to a syrupy, colorless liquid, which may again be cooled to $10^{\circ} C.$ ($50^{\circ} F.$), and remains fluid unless a crystal be dropped into it, when it again solidifies. Acetic acid of any

form should not be kept in bottles stopped with rubber, as it is liable to be contaminated by substances used in the vulcanizing of the rubber. Glacial acetic acid dissolves camphor, oils, both volatile and fixed, gum-resins, resins, albumen, and fibrin. In contact with the skin it destroys the epidermal tissues and even produces vesication. It is thus described by the *U. S. P.*: "Nearly or quite absolute acetic acid. A clear, colorless liquid, of a strong, vinegar-like odor, and a very pungent, purely acid taste. When the acid is cooled to a temperature as near as possible to 15° C. (59° F.), but yet in a liquid form, its specific gravity should not be higher than 1.058, corresponding to at least 99 per cent of absolute acid. At a temperature somewhat below 15° C. (59° F.), the acid becomes a crystalline solid. When crystallized by cold it becomes liquid again at about 15° C. (59° F.). At 117° to 118° C. (242.6° to 244.4° F.) it boils, evolving inflammable vapors. Glacial acetic acid corresponds in properties to acetic acid (see *Acidum Aceticum*), and should respond to the same tests of purity; but the tint produced by the addition of 2 drops of decinormal potassium permanganate V.S. to 2 Cc. of the acid diluted with 10 Cc. of water, contained in a clean, glass-stoppered vial, should not be changed to brown within two hours. To neutralize 3 Gm. of glacial acetic acid should require not less than 49.5 Cc. of potassium hydrate V.S. (each cubic centimeter corresponding to 2 per cent of the absolute acid), phenolphthalein being used as indicator"—(*U. S. P.*).

III. ACIDUM ACETICUM (*U. S. P.*). *Acetic acid.*

Preparation.—The acetic acid of commerce is derived from the action of sulphuric acid on pure sodium acetate, and indirectly from pyroligneous acid. Even fractional distillations of the latter acid, as pursued in obtaining rectified wood vinegar, will not completely purify it and chemical means must be resorted to in order to obtain pure acetic acid. Several methods are in vogue for this purpose. By the older method the crude pyroligneous acid was neutralized with milk of lime and the wood naphtha then distilled off; the remaining solution yielded upon evaporation to dryness a tarry residue of *brown acetate of lime*, containing only 68 to 69 per cent of pure acetate. By a later method, it is preferred to add milk of lime to the rectified wood vinegar (purified pyroligneous acid) and thus obtain by evaporation to dryness, a *gray acetate of lime* of much greater purity, containing 85 to 86 per cent of pure acetate.

Free acetic acid is then liberated from the acetates by distilling them with sulphuric acid, or preferably with hydrochloric acid which is added in a quantity just sufficient to convert the calcium into CaCl_2 . It is also preferred to convert the calcium acetate into sodium acetate before distilling with acid, by the double decomposition of calcium acetate and sodium sulphate. The sodium acetate is then carefully purified by evaporation and repeated recrystallization, finally being fused in an iron vessel, stirred until dry, and gently heated to incipient carbonization, thus ridding it of remaining empyreumatic impurities, and pure sodium acetate results. By distilling this salt with about 35 per cent of its weight of sulphuric acid the acetic acid of commerce is obtained. The remaining smoky flavor and odor may be removed by passing it through animal charcoal, or distilling it with bichromate of potassium.

Description.—Acetic acid of commerce is a solution of pure acetic acid in water, and according to the *United States Pharmacopeia* should contain 36 per cent of the stronger acid. It should be clear, colorless, free from empyreuma, of a pure, intense sour taste, and of an acetous odor. Its specific gravity is about 1.048 at 15° C. (59° F.) (*U. S. P.*). It mixes freely with water and alcohol in all proportions, and should volatilize completely without residue (*U. S. P.*). Acetic acid gives rise to a line of salts known as the acetates. The salts (most of them are soluble) in solution, upon the addition of a solution of ferric salts, acquire a dark brown-red color, which vanishes when hydrochloric acid is added. If acetic acid be neutralized (or even left slightly acid) with solution of ammonium hydroxide and treated with the pharmacopœial test solution of ferric chloride, a blood-red color results which may be discharged by adding to it an excess of sulphuric acid. The quality and odor of acetic acid are developed with age. According to Dr. E. R. Squibb, a sample of the freshly distilled acetic acid tested by the odor would not be recognized as the same substance a few months later.

Many methods have been given for determining the amount of absolute acid in a given sample of the official preparation. The following test is accurate and will answer all practical purposes. Treat 200 grains of the acetic acid with a weighed excess of dry, pure calcium carbonate. Wash from it the calcium acetate thus formed, dry the residue, and weigh the insoluble carbonate. Multiply the loss in grains by three-fifths which will give the percentage strength of absolute acid.

Tests.—"When the acid is slightly supersaturated with ammonia, the liquid should not have a bluish tint (absence of copper), nor should any residue be left after evaporating the alkaline liquid on the water-bath (absence of other fixed impurities). Acetic acid diluted with 20 volumes of water should neither become colored nor yield a precipitate with hydrogen sulphide T.S. (absence of lead, copper, etc.). Acetic acid diluted with 10 volumes of water should not yield a precipitate or turbidity with barium chloride T.S. (absence of sulphuric acid), or with silver nitrate T.S. (absence of hydrochloric acid). If a portion of the acid be just neutralized by ammonia, then mixed with some silver nitrate T.S., and warmed, the liquid should not turn dark-colored or deposit a dark-colored precipitate (absence of formic or sulphurous acid). When the acid is slightly supersaturated by sodium or potassium hydrate T.S., the liquid should not have a smoky odor or taste. And if 5 drops of decinormal potassium permanganate V.S. be mixed with 2 Cc. of the acid previously diluted with 10 Cc. of water, and contained in a clean, glass-stoppered vial, the pink tint should not change at once to brown, but should change only gradually, and not become entirely brown, or free from pinkish-brown, in less than half a minute (limit of empyreumatic substances). To neutralize 6 Gm. of acetic acid should require 36 Cc. of normal potassium hydrate V.S. (each Cc. corresponding to 1 per cent of the absolute acid), phenolphthalein being used as indicator" (*U. S. P.*). (See also *Acidum Destillatum*).

IV. ACIDUM ACETICUM DILUTUM (*U. S. P.*).—*Diluted acetic acid.*

Preparation: According to the *British Pharmacopœia*, this form contains acetic acid 1 part, distilled water 7 parts, by measure. These proportions are to be preferred to those of the *U. S. P.*, which directs a mixture of 100 parts of acetic acid to 500 parts of distilled water. The former preparation is about the strength of ordinary vinegar, and is to be preferred on that account inasmuch as it can be conveniently used in preparations where vinegar is directed, making a much finer preparation.

Description: According to the *United States Pharmacopœia*, "Diluted acetic acid contains 6 per cent, by weight, of absolute acetic acid. Specific gravity, about 1.008 at 15° C. (59° F.). It corresponds, in properties to acetic acid (see *Acidum Aceticum*), and should respond to the same tests of purity. To neutralize 24 Gm. of diluted acetic acid should require 24 Cc. of potassium hydrate V.S. (each Cc. corresponding to 0.25 per cent of the absolute acid), phenolphthalein being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Applied to the skin glacial acetic acid will cause vesication followed by a painful sore. Acetic acid acts upon the integument as a mild irritant unless its contact be prolonged, when it blisters and finally destroys the epidermis. Mucous tissues are turned first white and then brown by it. If a large dose be swallowed violent, burning, gastric pain with vomiting and diarrhœa results. Cases of fatal perforation have occurred from accidental swallowing of this acid. It reduces temperature and slows the pulse when taken in diluted form. Its continued use produces changes in the blood corpuscles, by its action on the alkalinity of the blood. When it kills it does so by arresting the heart's action. Convulsions and coma have preceded death when glacial acetic acid has been swallowed, and when not fatal it has produced gastro-enteritis. In cases of poisoning by this acid weak alkaline solutions should be immediately administered, followed by the use of milk and mucilaginous drinks. The stomach-pump should be employed to evacuate the stomach.

I. PYROLIGNEOUS ACID. Fish and meats, fresh or salted, immersed for a few seconds in crude pyroligneous acid, acquire a smoky taste, and are as well cured as by the usual method of smoking, besides being preserved from "skip-

pers." Silliman found that if a quart of this acid be added to the pickling liquid when hams are packed in it, they would have as perfect a smoky flavor as if they had gone through the usual process of preparation by smoking. This acid is stimulant and antiseptic. The diluted acid may be used as a local application for arresting or preventing sloughing, for cleansing old or gangrenous sores, abscesses, and burns, scalds, ringworms, tinea capitis, excoriated nipples, etc., and as a gargle in inflamed and ulcerated throat, and scarlatina maligna. Internally, in doses of from 10 to 30 drops, it is useful in all cases where an antiseptic is indicated. The pyroligneous tar forms a valuable irritating plaster.

II. GLACIAL ACETIC ACID. This acid attacks flesh and is too concentrated for internal use. It destroys the epidermis and may produce a painful sore. It may be used to destroy growths, such as warty excrescences, corns, and occasionally as a vesicant. This form of acid is one of our best agents for the cure of ringworm. The parts should be touched with a hair pencil dipped in the acid. Ulcers, papillomata, lupus, epithelioma, and nasal polypi have been successfully treated with it. It is an excellent application in scald head, though care should be exercised in its use not to produce an ulcerated condition of the scalp. M. Ricord speaks highly of this acid as a local application to venereal ulcers in the primary stage, to be applied as freely as any other caustic, and repeated as often as the condition of the chancres may require. Under its influence the ulcer speedily assumes a healthy aspect and promptly heals. He believes that it neutralizes the venereal poison, and thus obviates all danger of constitutional symptoms.

III. ACETIC ACID. Acetic acid is well known for its property of preserving vegetable substances, such as pickles, etc. It is antiseptic, refrigerant, astringent, and excitant. Its volatility renders it efficient for inhalation in cases of fainting, suffocation, headache, and hoarseness. A small quantity of acetic acid poured into the vessel containing the feces of typhoid fever patients, as well as those suffering from tubercular consumption and tubercular diarrhoea, will destroy the offensive odor arising therefrom. Acetic acid is claimed to be the only agent that will "liquefy and disorganize cancer cells." For this purpose a dilution of acetic acid has been applied to epitheliomata for the purpose of destroying the nature of the growths. This must be done, however, before the axillary or other glands have become involved. Fair success has attended this practice which is to be pursued only when the patient refuses to have the cancerous growth removed. Injected hypodermatically into nasal polypi, pure acetic acid has been found to quickly cause the tumors to shrivel and drop away. Should they suppurate and become offensive, deodorants, such as asepsin or borax, may follow its use to overcome the stench arising therefrom. Acetic acid 1 part, distilled water 2 parts, has been of service as an injection in gonorrhoea.

IV. DILUTED ACETIC ACID. Diluted acetic acid is always an efficient antidote for poisoning by the caustic alkalis. If this be not at hand diluted vinegar (which is an impure acetic acid) is always to be obtained and should be employed in such cases. This acid applied to an urticarious eruption will usually allay the disagreeable itching. It checks moderate hemorrhages, consequently it may be given in hematemesis, and applied to superficial wounds and in the nose for the relief of epistaxis. It may be applied to ringworm when it is not desirable to employ the stronger acid. Used as a lotion it will prevent the occurrence of bed sores, and added to the bath will frequently be beneficial in reducing temperature in febrile conditions. Vinegar may be employed for the same purposes. Diluted acetic acid has been given to check the colligative sweating of phthisical patients. Acetic acid is not often used internally, but when so used this form is selected, and the indications below given are the guides to its use.

Specific Indications and Uses.—Deep redness of tongue and mucous surfaces.

Preparations.—CAMPHORATED ACETIC ACID. Half an ounce of camphor triturated with a little alcohol to reduce it to powder, and then dissolved in 6 fluid ounces of this acid, forms the Camphorated Acetic Acid of the Dublin Pharmacopœia, which is a pungent stimulant when snuffed up the nostrils; as it is extremely volatile, and corrodes nearly all common metals except gold, it should be kept in glass vials, with ground-glass stoppers. Henry's aromatic vinegar is merely an acetic solution of camphor, oil of cloves, lavender, and rosemary.

Related Acids.—ACIDUM TRICHLORACETICUM, Trichloracetic acid, (CCl_3COOH). When chlorine acts upon acetic acid chloracetic acid in three modifications is formed accordingly as

the hydrogen atoms are replaced with one, two, or three atoms of chlorine, resulting respectively in *mono-chloracetic*, *di-chloracetic*, and *tri-chloracetic acids*, the latter of which is used in medicine. It may also be prepared by acting upon anhydrous chloral with fuming nitric acid—a process of oxidation. It forms colorless, very hygroscopic, rhombic crystals, having a faintly pungent smell, and strongly reddening litmus. At 55° C. (131° F.) it fuses; at 195° C. (463° F.) it boils. Chloroform (CHCl_3) and carbon dioxide (CO_2) are formed when it is decomposed by boiling with an excess of sodium carbonate. It has been used from full strength to 50 per cent solutions as a cauterant, and is likewise used in urinary analysis as a test-reagent for albumen (Coblentz). As a cauterant it is said to cause less pain than the commonly employed caustics, and the pain (in mucous tissues) may be wholly obtunded by the previous application of cocaine. In its action it somewhat resembles nitric acid, penetrating deeply without much inflaming the surrounding tissues, and the small, dry, and smooth, white eschar soon falls off, exhibiting granulations, and the sore very quickly heals. Very little contraction takes place and the scar is inconsiderable. It has been employed for the removal of *papillomata*, *lupus*, *vascular naevi*, *warts*, *condylomata*, and various *neoplasms*. To a limited extent it has been used to cauterize the mucous surface after the removal of *exuberant growths of the middle ear* (Foltz). A 20 per cent solution has been affirmed (Lanz) to cure obstinate *gleet* by cauterization.

ACIDUM ARSENOSUM (U. S. P.)—ARSENOUS ACID.

FORMULA: As_2O_3 MOLECULAR WEIGHT: 197.68.

SYNONYMS: *Arsenic*, *Arsenicum album*, *White arsenic*, *Arsenious anhydrid*, *White oxide of arsenic*, *Arsenious oxide*, *Arsenious trioxide*, *Arsenic trioxide*, *Arsenious acid*.

History and Source.—Geber was the first to mention white arsenic, stating that he obtained it by roasting the sulphide of arsenic. Albertus Magnus was the first to state that a metal-like substance was contained in white arsenic. The element is found native in the Hartz Mountains and in Hungarian and Bohemian mines, but occurs more frequently in combination with sulphur as realgar and orpiment, or combined with sulphur and iron as arsenical pyrites or mispickel. This form of pyrites may be found in the New England States, particularly Connecticut and New Hampshire. It also occurs in combination with iron, cobalt, nickel, tin, and silver (as arsenides). It is present, to a slight extent, in some mineral springs and in the ashes of certain plants. It has been found, according to Orfila in the soil of cemeteries.

Preparation and Description.—Arsenous acid is obtained on a large scale in Saxony and Bohemia, mostly as a by-product, in the roasting of arsenical ores. The vapors of the trioxide formed are condensed in the form of crude flowers of arsenic, a white crystalline powder. In the Silesian works at Altenburg and Reichenstein it is obtained in large quantities from the smelting of arsenical iron pyrites. The crude product is purified by repeated sublimation.

The U. S. P. describes it as follows: "A heavy solid, occurring either as an opaque, white powder, or in irregular masses of two varieties—the one amorphous, transparent, and colorless, like glass; the other crystalline, opaque, or white, resembling porcelain. Frequently the same piece has an opaque, white, outer crust enclosing the glassy variety within. Contact with moist air gradually changes the glassy into the white, opaque variety. Both are odorless and tasteless. In cold water both varieties dissolve very slowly, the glassy variety requiring about 30, the porcelain-like about 80 parts of water at 15° C. (59° F.). Both are slowly but completely soluble in 15 parts of boiling water. In alcohol, arsenous acid is but sparingly soluble, but it is soluble in about 5 parts of glycerin. Oil of turpentine dissolves only the glassy variety. Both varieties are freely soluble in hydrochloric acid, and in solutions of alkali hydrates and carbonates"—(U. S. P.).

The specific gravity of the transparent variety is 3.73; of the opaque, 3.69. It is brittle, breaking with a shell-like fracture. Tartaric acid increases its solubility; it is insoluble in ether. It is incompatible with lime-water and decoction of barks generally.

Tests.—The Pharmacopoeial tests are as follows: "When heated to 218° C. (424.4° F.), arsenous acid is completely volatilized without melting. When thrown on ignited charcoal, it emits an alliaceous odor. When its vapor is passed through red-hot charcoal, in an arsenic-tube, it is deoxidized, and metallic arsenic is deposited on the cooler portion of the tube as a mirror having a metallic luster. An aqueous solution of arsenous acid has a faintly acid reaction upon litmus paper. Silver ammonium nitrate T.S. produces in the solution a lemon-yellow

precipitate, which dissolves on addition of ammonia water; when this solution is heated, metallic silver is deposited (distinction from arsenic acid). Copper ammonium sulphate T.S. produces a bright green precipitate, which dissolves in ammonia water with a deep blue color. Hydrogen sulphide T.S. colors the solution of arsenous acid yellow; if a few drops of hydrochloric acid are added, it precipitates lemon-yellow arsenic trisulphide, which should be completely soluble in ammonium carbonate T.S. (absence of antimony, tin, and cadmium). When arsenous acid is carefully heated in a dry test-tube of hard glass it should sublime without leaving a residue, and the sublimate should not at first show a yellow color (absence of non-volatile matter and of arsenic sulphide). If 1 part of arsenous acid be dissolved in 10 parts of ammonia water, with the aid of a gentle heat, the solution should neither leave an insoluble residue, nor show a yellow or other color; nor should the addition of a slight excess of hydrochloric acid produce a precipitate (absence of metallic impurities, sulphides, etc.). If 0.1 Gm. of arsenous acid be dissolved, together with 1 Gm. of sodium bicarbonate, in 20 Cc. of water by the aid of a gentle heat, it should decolorize not less than 20 Cc. of decinormal iodine V.S. (corresponding to at least 98.8 per cent of arsenic trioxide)"—(U. S. P.).

In addition the following tests for arsenic and its oxides are of importance:

Marsh's Test: Take a Woulff bottle with double tubulature, provide each with a perforated cork; through one of these fit a funnel tube reaching to nearly the bottom of the bottle; connect the other tubulature by means of a bent glass tube with a horizontal wide tube containing a layer of pieces of caustic potash and one of calcium chloride, and by means of a tight-fitting cork add a narrower horizontal tube of hard glass, narrowed in one or two places and ending in a tapering jet bent upward. Place into the bottle some pure zinc, free from arsenic, and add through the funnel tube a mixture of 1 part of arsenic-free sulphuric acid and 5 parts of water. When all the air in the apparatus is displaced by the hydrogen gas (which is best ascertained by collecting the gas in a test-tube and igniting its contents in the flame of a spirit lamp) ignite the hydrogen issuing from the tapering end, and add through the funnel tube the liquid to be tested. If arsenous acid is present, AsH_3 will be formed (arseniuretted hydrogen, arsin), which turns the otherwise faintly blue hydrogen flame a luminous, bluish-white color, and in burning produces white fumes of arsenous oxide.

The following reactions will establish the identity of arsenic present:

1. Hold a cold plate of porcelain into the flame of AsH_3 , taking the precaution to nearly touch the glass jet. AsH_3 is then decomposed, and a black spot of arsenic is deposited upon the plate, soluble in solution of sodium hypochlorite (distinction from antimony). The arsenic spots are also soluble in warm nitric acid. If a drop of AgNO_3 be added, and a drop of aqua ammoniæ held over it, a yellow spot of silver arsenite or a red spot of silver arsenate is formed. Antimony under like conditions causes a black precipitation of silver and some antimony.

2. Heat the tube through which the AsH_3 passes by means of a spirit lamp; a mirror of metallic arsenic will be deposited in the colder parts of the tube. If afterward sulphide of hydrogen is passed over the metallic mirror, at the same time warming it, it is transformed into lemon-yellow, As_2S_3 . (The corresponding antimony compound would be orange-red.)

Marsh's test is especially available for the detection of arsenic in cases of poisoning, for which purpose the suspected organic substances are previously treated, under certain precautions, with strong sulphuric acid, later with nitric acid (Danger and Flandin), or preferably with hydrochloric acid and potassium chlorate (Fresenius and Babo).

Reinsch's Test: If an aqueous solution of arsenous acid be boiled for 10 or 20 minutes with one-tenth to one-sixth its bulk of pure hydrochloric acid, and fine copper gauze, or thin copper wire, the latter acquires an iron-gray metallic coating of arsenic. If now the coated copper be washed, dried, cut into small pieces, and then heated in a glass tube or reduction tube by the flame of a spirit lamp, the metallic arsenic is volatilized, and sometimes yields a metallic ring; but in general it becomes oxidized, and yields a sublimate of minute octahedral crystals. The arsenous acid thus obtained in the tube should be dissolved in

water and tested with hydrogen sulphide, ammonio-nitrate of silver, etc., or it may be tried by Marsh's process. In using Reinsch's test great care should be taken in ascertaining the purity of the copper, as arsenic is often present.

When the arsenous acid is contained in organic substances, as stomach, liver, etc., these must be cut into small pieces, and boiled in water acidulated with hydrochloric acid, until all the tissues are dissolved, or broken down into fine flakes or grains. Filter through calico, heat again to the boiling point, and proceed by Reinsch's process, as previously described.

Bettendorff's Test: To a small quantity of the liquid to be tested add pure concentrated hydrochloric acid and an equal volume of a saturated solution of freshly-prepared stannous chloride in pure hydrochloric acid. The presence of arsenic is revealed by the production of a brown color or brown precipitate, the appearance of which is hastened by a gentle heat.

Fleitmann's Test: See *Reagents and Test Solutions*.

Action and Toxicology.—Arsenic in very small doses accelerates the circulation, and has a tonic effect on the nervous system. It enables one to take active exercise with but little fatigue, and without materially interfering with respiratory action. Certain arsenic-eaters among the Styrians become habituated to its use, taking as much as 4 to 10 grains daily. They are careful, however, not to drink water for some time after taking it.

In large doses, arsenous acid is a most violent poison, producing in overdoses, nausea, vomiting, burning pain of the throat and stomach, soon extending over the whole of the abdomen. Although under certain circumstances, a large amount of arsenous acid has been swallowed without any serious effects, yet as a general rule, it is considered that death may be produced by 1 or 2 grains of it taken at a dose. A larger quantity may cause vomiting so quickly as to expel it from the stomach before its deleterious action fairly commences; and a distension of the stomach with food has prevented it from proving fatal. Yet there is much uncertainty in these matters, as experience has demonstrated. When emesis is caused by its poisonous action, the matters vomited may be bilious or tinged with blood, occasionally there will be no pain or vomiting. There is very apt to be a sense of heat, dryness, and constriction of the throat, with incessant thirst and great difficulty of swallowing. When the bowels are inflamed the abdomen is tense and hard, with loose, bloody stools, tenesmus, heat, and excoriation of the anus. The urine may be diminished or suppressed; pulse quick, small, feeble, and irregular; heart beating irregularly with palpitation; breathing laborious and often painful; tongue dry and furred; with frequently tremblings, cramps, and delirium previous to death; occasionally dark spots or an eruption on the surface will be present. The symptoms are by no means uniform, and will vary with different individuals; there may be faintness, or actual syncope, convulsions, paralysis, great prostration, coma, etc. In some cases death may ensue without any severe or well-marked symptoms. When arsenic is taken in small doses, continued for a long period, but acting as a slow poison, "there will be a gradual sinking of the powers of life, without any violent symptom; a nameless feeling of illness, failure of the strength, an aversion to food and drink, and all the other enjoyments of life." Among the many symptoms which have been observed in such cases, the following are the principal: flatulence, heat or pain in the stomach and bowels, loss of appetite, thirst, nausea, vomiting, purging, or a loose condition of the bowels, with griping; the tongue furred, mouth and throat dry and constricted, and sometimes salivation. The pulse will be quick, small, and often irregular; a dry cough, with oppressed respiration; wasting of the body; very irritable stomach, immediately rejecting anything thrown into it. Headache, giddiness, wakefulness; irritation of the conjunctiva, the patient frequently complaining of a feeling like a hair or cobweb in the eye, with redness, swelling or pricking of this organ; the limbs painful, feeble, trembling, subject to numb sensations, cramps, or convulsions. An eruption on the surface, falling off of the hair and nails; swelling of the face and feet, and gradual sinking of the patient, with consciousness perfect to the last, or perhaps coma, or delirium. Arsenic, whether taken internally or absorbed from its external application to a wound, almost always occasions gastritis or gastro-enteritis. Beside the stomach and bowels, it also appears to exert a

specific influence over other parts of the system, as the heart, nerves, lungs, skin, etc., causing irritation, inflammation, and gangrene, as may be observed by an inspection of these organs after death. Applied to the skin, especially if the epidermis be removed, it acts as a powerful caustic.

In the treatment of cases of poisoning by arsenic, the first thing to be done is to remove as much of the poison from the stomach as possible, either by employing the stomach-pump, or producing vomiting by tickling the throat and fauces with a feather or the finger, and emetic doses of sulphate of zinc, or sulphate of copper. None of the nauseating emetics must be used, as lobelia, ipecacuanha, etc., as they do not act with sufficient promptness, and favor absorption of the poison by their prolonged nausea previous to vomiting. To sheathe the stomach, and at the same time diminish the solubility of the arsenous acid, demulcents (as milk, white of egg, mucilage, syrup, etc.), and lime-water may be used freely; these likewise promote vomiting. If it is supposed that any of the poison has entered the intestines, the best purgative for its expulsion is castor-oil.

Antidotes should be administered as soon as they can be had; several have been named, as charcoal, and light calcined magnesia, swallowed in large quantities. But the best antidote is, the recently made, pulpy, hydrated sesquioxide of iron (hydroxide of iron), prepared by precipitation with ammonia. It should be given to an adult in tablespoonful doses every three or four minutes, until the severe symptoms have ceased. Dr. MacLagan observes "that as far as chemical evidence goes, at least twelve parts of oxide, prepared by ammonia, and moist, are required for each part of arsenic." The hydroxide of iron may, however, be given in much larger amount, as it is completely free from any deleterious action; and the sooner it is given after the poison has been swallowed, the more prompt and certain will be its effects. It forms with the poison an innocuous salt, the ferrous arsenate.

Any inflammatory symptoms which may be present, excessive pain, or great prostration, must be treated on general principles; and great care should be observed during convalescence, which is apt to be very tedious, to keep the patient upon fluids only, of a nutritious character, permitting no solids, until all danger of gastro-enteritis has passed.

Action and Medical Uses.—Arsenic is a very positive medicinal agent when properly employed, and one capable of incalculable injury when injudiciously administered. As Prof. Scudder has very properly indicated, the dose should be very small, and the remedy should never be employed unless the indications for its use are clearly present. That much of the discredit that has fallen upon this agent is due to its indiscriminate use in inordinate doses, we are fully satisfied. That it is a blood-maker, improves nutrition, and is a powerful vital stimulant, is well established, and it is in this direction that it has been used by Eclectic practitioners. From a series of experiments in dosage, Profs. Howe and Locke came to the conclusion that the most favorable and proper medicinal dose of Fowler's solution, the most commonly employed preparation, should be one-half drop. The conditions calling for arsenical preparations are a low condition of the blood with a tendency to the deposition of cacoplastic material—imperfect albuminoids—caseous and yellow tubercular formations, tissue degeneration, and impaired nutrition. Irritability and erethism of the nerve centers, and particularly of the sympathetic system, always contraindicate its use.

Arsenic has long been a remedy for *malarial affections*. In properly selected cases its action is admirable. These cases are those exhibiting torpor of the sympathetic centers with a general lack of nervous excitation. The malarial cachexia is marked and the periodicity irregular. The pulse is weak and compressible, limbs cold, tongue pale and without expression, and the tissues flabby. Added to these, in these disorders as well as in all cases calling for arsenic, we observe a muddy or dirty hue of the skin, and when a fold of the latter is taken between the fingers it retains the pinched-up form, very slowly returning to its natural condition, thus lacking that elasticity possessed by the cutaneous tissues in health. Such conditions in *adynamic typhoid states* indicate arsenicum. In *atonic diarrhoea* with indigestion, in *cholera infantum* with marked enfeeblement, and frequent, thin, non-mucoid discharges, and in periods of great depression followed by hectic fever, arsenic exhibits its curative power, the indications above

given being always present. Here it undoubtedly cures by its action as a nerve stimulant. R Fowler's solution, gtt. x; aqua, fl̄iv. Mix. Sig. Dose, a teaspoonful every two or three hours.

Anemia has been very successfully treated with small doses of arsenicum. It is adapted where the constitutional debility is marked, and the nervous forces greatly depressed. Webster asserts it of most value in *chlorotic conditions* associated with *metrorrhagia* and *choreic complications*; also in the *anemia of malarial cachexia*, though in the latter instance he prefers the arsenate of quinine to arsenic itself. Rare cases of *pernicious anemia* have been benefited by it. *Puerperal* and *dyspeptic anemia* sometimes yield to it.

Howe, Scudder and others have pointed out the value of arsenic in *tubercular disorders*. Prof. Howe used Fowler's solution and veratrum very extensively in *phthisis*. The arsenical preparation was usually prescribed as follows: R Fowler's solution, fl̄ss; syr. lactophosphate of calcium, fl̄vj. Sig. Dose, a teaspoonful 3 times a day every other day. *Chorea* and *obstinate neuralgias* are favorably impressed by arsenic. The former is most amenable when associated with malarial cachexia, or with chlorotic anemia. Quite large doses are sometimes permissible in this condition, though as a rule, when indicated, the small doses succeed best. The neuralgias best met by it are those of a miasmatic type, especially when confined to the intercostal and fifth cranial nerves. In fact most neuralgias are more or less benefited by it, for the majority are due to general debility. In all these conditions where malaria forms a part of the trouble, the arsenate of quinine in 2x trituration acts nicely. Arsenic bromide seems to have some claim to efficiency in *epilepsy*, and has been recommended in *diabetes mellitus*.

Excellent results have been obtained from the use of arsenicals in *chronic gastritis* with burning sensations and where the trouble is due to cutaneous eruptive retrocessions; in *duodenitis*; and in *cholera infantum*, during the last stages, the arsenite of copper relieves the intestinal pains, checks the discharges, and exerts its tonic effect. *Semi-chronic dysentery* with impaired vitality of the mucous tissues is favorably impressed with arsenic. In all these conditions the minute dose is to be preferred.

It is in *skin affections*, however, that arsenic has had the widest application. Even when used indiscriminately its effects have largely been favorable, but brilliant results have attended it when specifically applied. Here the general indications above given apply, and the classes of disorders are those of a chronic nature of the squamous, vesicular, and tubercular types, and sometimes those of a pustular character. Long continued use of the small doses is necessary. The affections in which it has proved of value are *eczema*, *psoriasis*, *lupus*, *lepra*, *pityriasis*, *impetigo*, *ichthyosis*, *elephantiasis*, *pemphigus*, *warts*, *prurigo* and *lichen ruber*, etc. Syphilitic manifestations are not much benefited by arsenic alone, though *articular nodosities* of syphilitic origin are said to have been benefited by it. Donovan's solution, however, is of benefit in *secondary syphilis* with the tongue small and unduly red.

Applied externally, after removing the epidermis, arsenous acid is a powerful caustic, used in the treatment of *cancerous ulcers*, *lupus* or *noli me tangere*, *epithelial cancer*, *onychchia maligna* and *chancres*; but its application requires the greatest caution, on account of fatal accidents which might occur from its absorption, as well as from the erysipelatous inflammation it is apt to occasion. It is seldom employed for this purpose by reputable physicians, though it forms a large element in the "cancer cures" of so-called "cancer specialists." It has been applied in various forms, thus: 1. Arsenous acid, sublimed sulphur, of each 1 drachm, spermaceti cerate 1 ounce; to be applied on lint, for 24 hours, and then to be removed—when the slough comes away, dress the ulcer with simple ointment. 2. Arsenous acid 2 grains, spermaceti ointment 1 ounce. 3. *Arsenical paste* (Rousselot's). Arsenous acid 1 part; red sulphide of mercury 16 parts; powdered dragon's blood 8 parts; applied over the ulcer. The *French Codex* prescribed 8 parts instead of one of arsenic. Various other forms, both for the internal and external use of arsenous acid, have been recommended by members of the profession.

Arsenic is largely used in *dental surgery* to insert into dental cavities for the

purpose of destroying the nerve pulp. It is a very painful application, though it is generally combined with creosote, or carbolic acid and morphine, which somewhat obtund the pain. From $\frac{1}{16}$ to $\frac{1}{8}$ grain is inserted and covered in such a manner that it can not escape from the cavity.

The dose of arsenous trioxide is from $\frac{1}{16}$ to $\frac{1}{8}$ grain; in 2x or 3x trituration, 3 grains 3 or 4 times a day; Fowler's solution, fraction of a drop to 5 drops; liquor acidi arsenosi (1 per cent), 1 to 5 drops; liquor sodii arsenitis (U. S. P.), 1 to 5 drops; arsenic iodide, $\frac{1}{16}$ to $\frac{1}{8}$ grain; Donovan's solution, 1 to 5 drops; Clemens' solution (bromide of arsenic), 1 to 3 drops a day, well diluted, after meals; arsenate of quinine, 2x trit., 3 grains 3 or 4 times a day.

The administration of arsenicals must be at once stopped when they produce swelling of the face and eyelids, with irritation of the conjunctiva, and disorder of the digestive organs.

Specific Indications.—Skin muddy, dull, sallow or pallid, and inelastic; epidermis dry; irregular periodicity in malarial cachexia; squamous, vesicular, and tubercular skin affections; deposits of low albuminous matter, yellow tubercle and caseous formations; impaired sympathetic innervation and general lack of nerve force; pulse soft and easily compressed; extremities cold; secondary syphilis with tongue small and increased in redness (Donovan's solution only); pallid, cedematous skin; muscles flabby. Periodicity not cured by quinine; eyes dull; tendency to hemorrhage; tongue pale and expressionless.

Preparations.—**FOWLER'S SOLUTION.** (*Liquor potassii arsenitis. Arsenical solution.*) Solution of arsenite of potassium, representing 1 per cent of arsenous acid.

DONOVAN'S SOLUTION. (*Liquor arseni et hydrargyri iodidi.*) Contains 1 per cent each of iodide of arsenic and red iodide of mercury.

LIQUOR ACIDI ARSENI. A 1 per cent solution of arsenous acid.

PEARSON'S ARSENICAL SOLUTION. Solution of arsenate of sodium.

DE VALANGIN'S SOLUTIO SOLVENTIS MINERALIS. (*Liquor arsenici chloridi.*) A solution of chloride of arsenic.

ASIATIC PILLS. Contain arsenous acid $\frac{1}{16}$ gr., black pepper $\frac{1}{2}$ gr., mucilage of acacia q. s., to form a pill. (For preparation of above solutions, see Liquors.)

Related Compound.—**SMALT.** **SMALTS.**—Cobaltic oxide (impure) prepared by roasting native cobaltic arsenide, and fusing the product with potassa and sand. The result is a handsome blue glass, which, when powdered, is given the above names. It is used for coloring glass, porcelain, etc., and in sign painting.

ACIDUM BENZOICUM (U. S. P.)—BENZOIC ACID.

FORMULA: $\text{HC}_6\text{H}_5\text{O}_2 = \text{C}_6\text{H}_5\text{COOH}$. **MOLECULAR WEIGHT:** 121.71.

SYNONYMS: *Acidum benzoicum sublimatum, Flowers of benzoïn, Flowers of Benjamin, Flores benzoës.*

"An organic acid, usually obtained from benzoïn by sublimation, or prepared artificially, chiefly from toluol. It should be kept in dark, amber-colored, well-stoppered bottles, in a cool place"—(U. S. P.).

Source and History.—Benzoic acid is a characteristic constituent of many balsam-resins. It is contained in benzoïn, storax, liquidambar, castoreum, balsams of tolu and Peru, and other resinous bodies. The principal source, however, is from gum benzoïn, though on account of the scarcity of benzoïn yielding profitable quantities of the acid, Botany Bay resin is often used, and as a rule gives a larger yield than that obtained from true benzoïn. There are two kinds of benzoic acid on the market, viz.: English and German. The former is obtained by sublimation of the above-mentioned gums; the latter from the urine of herbivorous animals and from coal-tar products. That made from benzoïn only should be used by the druggist and doctor.

Vigénère, as far back as 1608, described benzoic acid as one of the products resulting from the dry distillation of gum benzoïn. Lemery (1675), and Scheele, just 100 years later, both recognized it as an acid, and the process of preparation given by the latter is essentially one of the methods used in its production at the present time. It was discovered by Baron Liebig, in 1830, in the products obtained by distilling hippuric acid, and obtained from that acid by the action of acids and alkalies by Dessaignes in 1847.

Preparation.—Several modes of preparing benzoic acid have been given from

time to time. We shall only introduce here one dry and one wet method. The dry method, which is essentially that introduced by Mohr and adopted by the Pharmacopœia of the United States in 1870, is as follows: Into an iron dish about 8 or 9 inches wide and a couple of inches deep is introduced about 1 pound of benzoin, broken into coarse fragments or coarsely powdered, spread uniformly over the bottom of the vessel. Over the top of the dish is evenly stretched a piece of coarse filter-paper and pasted to the edges of the container. A hat-like, conical receiver is then made of well-sized paper, a little larger at the base than the diameter of the dish to which it is then attached by pasting it securely over the rim of the vessel. The dish, with its contents, is then placed in a sand-bath and gently heated not higher than 145°C . (293°F .) at the beginning, gradually raising the heat until 200°C . (392°F .) is reached. The vapors of the acid, which are held in combination with the resin, are thus liberated by the heat, and ascending pass through the bibulous paper and condense on the inside of the conical receiver, all empyreumatic oils being absorbed by the paper diaphragm as the vaporous acid passes through it. The heating should be continued 3 or 4 hours or until the acid vapors no longer rise. Should the paper diaphragm become clogged by the melting of the acid in any watery vapor that may be present, it should be removed and a new one inserted in its place. It occasionally happens that by jarring, or by some other means the condensed acid adhering to the receiving-cap becomes detached and falls upon the filter-paper, and thus becomes contaminated with the empyreumatic products held by it and liquefies, thus impeding the further passage of the vapor. Should this occur the fallen portion should be resublimed to rid it of impurities and a new diaphragm introduced. To prevent such an accident a layer or two of gauze or linen may be stretched above the paper division so that any falling particles would be caught by it, thus preventing its reaching the contaminated bibulous paper. A yield of about 7 or 8 per cent is realized by this method. By breaking up the fused mass left in the container and subjecting it again to sublimation an additional quantity may be obtained. An earthenware vessel may be used instead of an iron one, and the mass may be heated on a common stove-plate if desired, but great care should be exercised that the gum be not too strongly heated.

Scheele's wet method consisted in boiling benzoin in water and milk of lime, separating the resulting calcium benzoate while hot by filtration, and precipitating from the solution the benzoic acid by means of hydrochloric acid. The product is sometimes sublimed to give the appearance of the acid made by the dry method. This process yields about $13\frac{1}{2}$ per cent.

A commercial grade known as German benzoic acid is prepared by mixing the urine of horses and cattle with an excess of lime, and evaporating the solution to about one-twelfth of its bulk. The resulting calcium hippurate is then supersaturated with hydrochloric acid, liberating hippuric acid, which is purified by animal charcoal or other means. Hydrochloric acid is then added to the purified hippuric acid and boiled one-half hour, when benzoic acid and glycocholic acid ($\text{C}_6\text{H}_5\text{NH}_2\text{COOH}$) result. Benzoic acid obtained in this manner has a fetid, urinous odor, and is purified by recrystallization or by subliming it with a small quantity of benzoin. Benzoic acid is also cheaply produced on a large scale by synthetic methods from naphthalin (C_{10}H_8), a derivative of coal-tar, and from tolulol ($\text{C}_6\text{H}_5\text{CH}_3$), one of the products of the distillation of wood and coal and a constituent of commercial benzin. The greater portion of the artificial product is now prepared from tolulol by converting the latter into benzo-trichloride and heating this substance with water under pressure. The following reactions take place: $\text{C}_6\text{H}_5\text{CH}_3 + \text{Cl}_2 = \text{C}_6\text{H}_5\text{CCl}_2 + \text{HCl}$. $\text{C}_6\text{H}_5\text{CCl}_2 + \text{H}_2\text{O} = \text{C}_6\text{H}_5\text{COOH} + \text{HCl}$.

Description and Tests.—"Benzoic acid occurs in commerce in white, or yellowish-white, lustrous scales or friable needles, odorless, or having a slight, characteristic odor resembling that of benzoin, and of a warm, acid taste; somewhat volatile at a moderately warm temperature, and rendered darker by exposure to light. Soluble, when pure, in about 500 parts of water, and in 2 parts of alcohol at 15°C . (59°F .), in 15 parts of boiling water, and in 1 part of boiling alcohol. Also soluble in 3 parts of ether, 7 parts of chloroform, and readily soluble in carbon disulphide, benzol, fixed and volatile oils, but sparingly soluble in benzin. Benzoic acid volatilizes freely with the vapor of water. On heating it to

100° C. (212° F.) it begins to sublime. At 121.4° C. (250.5 F.) it melts, and at a higher temperature it is consumed without leaving a residue. The acid sublimed from benzoin has a lower melting point, and a greater solubility in water. Benzoic acid has an acid reaction. On heating benzoic acid gradually with 3 parts of freshly-slaked lime in a retort benzol is evolved. The acid is freely soluble in solutions of alkali hydrates. On carefully neutralizing such a solution, and adding ferric chloride T.S., previously diluted with 2 volumes of water, and neutralized, if necessary, by ammonia, a flesh-colored precipitate of ferric benzoate is produced. A solution of benzoic acid in pure, cold, sulphuric acid, when gently warmed, should not turn darker than light brown; if it is then poured into water the benzoic acid should separate as a white precipitate, and the liquid should be colorless (absence of readily carbonizable, organic matters). If 0.5 Gm. of the acid and 0.8 Gm. of calcium carbonate be mixed with a little water in a crucible, the mixture dried, gently ignited, and then dissolved in water, with the aid of nitric acid in slight excess, so as to obtain 20 Cc. of filtrate, the addition of silver nitrate T.S. to the latter should not produce much more opalescence (if at all) than is produced by the same reagent in a solution measuring 20 Cc. prepared by dissolving 0.8 Gm. of the same calcium carbonate in water with the aid of nitric acid (absence of more than traces of chlorine). On warming 0.5 Gm. of the acid with 5 Cc. of water and 0.5 Gm. of potassium permanganate in a test-tube loosely stoppered and placed in a water-bath heated to about 45° C. (113° F.), then tightly stoppering and cooling the test-tube with cold water, upon removing the stopper no odor of oil of bitter almond should be discernible (absence of cinnamic acid)"—(U. S. P.).

Benzoic acid is permanent at ordinary temperatures. If made from hippuric acid its appearance is often as fine, if not finer, than when produced from benzoin, but traces of a urinous odor can be detected in it. If the odor of benzoic acid resembles that of the sweat of horses it should be rejected. German benzoic acid is often a pure white, the object in later years having been to make it so that it will resemble that produced from the gum. Formerly the crystals produced by this process (artificially) were much the handsomest. It will be observed that though the Pharmacopœia recognizes both the natural and artificial product its description of the acid is so constructed that it can apply only to the true product produced from the gum, thus practically ruling out the artificial acid. Benzoic acid gives rise to a line of more or less soluble salts known as benzoates.

Action, Medical Uses, and Dosage.—Benzoic acid is destructive to bacterial forms of life, and equally as valuable as salicylic acid in arresting putrefaction. Infusion of gentian, orange, and buchu may be kept unimpaired for a month by the addition of $\frac{1}{2}$ gr. to the ounce of liquid (Benger). In bulk or in concentrated solution it acts, even in small doses, as a gastro-intestinal irritant, consequently it should be administered in large quantities of water. It excites a general sense of warmth throughout the system, and materially increases the secretions of the skin and pulmonary mucous surfaces. It was formerly used, to a considerable extent, in *broncho-pulmonary affections*. Its principal use now, however, is in disorders of the *urinary tract*. It prevents and corrects ammoniacal and other varieties of *fermentation of urine* in the bladder and renders the fluid more acid. If, however, the urine be excessively acid its use, by dissolving it in water by the aid of a small amount of sodium phosphate or carbonate, renders it less acid and thereby relieves the irritability of the cystic mucous lining. It is a certain remedy for *phosphatic gravel*, and is said to be equally serviceable when *vesical irritability* is due to excess of uric acid. *Cystitis*, when due to excessively alkaline urine, or to a urinous fermentation, purulent or non-purulent, is promptly benefited by this agent. Its action is purely local, and by thus acting as an anti-ferment it renders good service in *nocturnal enuresis*, *dysuria*, and *urethritis* when due to these fermentative changes. It is a good remedy for *gonorrhœa* when aggravated by ammoniacal or other putrid states of the renal secretions. It prevents the formation of incrustations, or *calculi* of ammoniaco-magnesian phosphate, by maintaining the acid quality of the urine. The *enuresis of children* and *urinal dribbling of old persons*, if due to excessive alkalinity, are greatly benefited by a couple of 5 to 10-grain doses daily. Prof. Scudder recommends it as a specific in "irritation of the sympathetic and spinal system of nerves with uric acid depos-

its" and as a stimulant for *brain exhaustion* in mentally-overworked individuals, with phosphuria—(*Specific Medication*). It is useful in *rheumatism*, but only in those cases showing markedly alkaline urine. It is believed to exert some influence on *jaundice*, due to obstruction of the bile ducts with inspissated bile, and has restored to its normal condition urine that was loaded with chyle. Benzoic acid reduces the quantity of albumen in *albuminuria*. It is one of the ingredients of paregoric, and is also employed in making many cosmetic washes. The dose ranges from $\frac{1}{4}$ to 30 grains, the moderate doses being preferred to correct excessive alkalinity of the urine.

Specific Indications and Uses.—Excessively alkaline urine; phosphuria; vesical irritability, with alkaline urine; fermentative urine; brain-fag, with phosphuria; "irritation of the sympathetic and spinal system of nerves with uric acid deposits"—(Scudder).

Derivative.—BENZOYL TROPEINE ($C_{15}H_{15}NO_2 \cdot 2H_2O$). Silky needles obtained by heating to $100^\circ C.$ ($212^\circ F.$) a mixture of tropine, benzoic acid, and dilute hydrochloric acid. It melts at $58^\circ C.$ ($136.4^\circ F.$); the anhydrous base at 41° to $42^\circ C.$ (105.8° to $107.6^\circ F.$). Its compounds are not readily dissolved. Filehne (1887) found benzoyl-tropeine to effect a powerful local anesthesia, and like other tropeines the muscles of accommodation and the pupils were affected by it. He also found other compounds of benzoyl to produce local anesthesia, *benzoyl morphine* being weakest, *benzoyl quinine* more powerful, while *benzoyl triacetonalkamine* was most active in this respect.

ACIDUM BORICUM (U. S. P.)—BORIC ACID.

FORMULA: H_2BO_3 . MOLECULAR WEIGHT: 61.78

SYNONYMS: *Boracic acid, Orthoboric acid, Acidum boracicum.*

Source, History, and Preparation.—This acid is found in nature in several species of plants, in the waters of the sea, and such mineral springs as Vichy, Wiesbaden, and Aix-la-Chapelle, as well as in several of the hot springs of America. It is found in nature in minerals, and especially in the niter regions of Chili and Peru, where it occurs as *borocalcite*. As a constituent of natural borax it has been discovered in enormous quantities in Borax Lake, California, and it also occurs in the same natural combination as *tincal* in the dried-up, saline lagoons or lake-beds of Thibet. Owing to the recent development of the borax industry along the Pacific coast, the major part of the boric acid consumed in the United States is now derived from the California deposits, while the greater part of the world is supplied from the extensive natural products from the volcanic rocks of Tuscany and the isle of Volcano, of the Lipari group, north of Sicily, where free boric acid occurs naturally under the name of *sassoline*.

On the volcanic mountain-sides of Tuscany are to be seen innumerable fissures which throw out jets of steam, called *suffioni*, charged with various gases and boric acid. Surrounding one or more of these crevices (also called *suffioni* or *soffioni*) may be seen either a natural basin or lagoon, or one constructed of masonry. Several of these circular lagoons are arranged on the mountain-side and made to connect with each other by a series of canals. Cold water from a mountain spring is then allowed to fill these basins, and receives the steamy vapors which either condense and flow into them, or else shoot up into them from the bottom. These jets constantly breaking into the water heat it and yield to it boric acid. This acid solution is then allowed to pass down the declivity into another lagoon and so on until, by receiving an added amount from each basin, it becomes saturated, when it is conducted into leaden pans, where it is evaporated to such an extent that when drawn off into wooden vats and cooled, it will deposit crystals of crude boric acid. This acid is then shipped to various countries where it is converted into borax either by boiling it with a soda solution, or fusing it with calcined carbonate of sodium. The latter method is usually employed. The medicinal boric acid is then made from the borax so produced. Boric acid was first made by Homberg (1702), after whom it was known as the "sedative salt of Homberg" (*sal sedativum Hombergi*). The medicinal acid may be prepared as follows: Take borax 10 parts, boiling water 24 parts. Dissolve the borax in the water and filter while hot. Mix with the filtrate 6 parts of chlorhydric acid and allow the mixture to stand in a cool place for 24 hours. Collect

the resultant crystals upon a strainer or in a funnel, wash them with cold water, and dissolve them again in 5 parts (by weight) of boiling distilled water, and allow the solution to stand for a few days. Re-collect the crystals, wash with cold water to free them from traces of foreign matter, and dry them in a moderately warm situation.

Description.—Boric acid occurs, according to the Pharmacopœia, in "transparent, colorless scales, of a somewhat pearly lustre, or, when in perfect crystals, six-sided, triclinic plates, slightly unctuous to the touch, odorless, having a faintly bitterish taste, and permanent in the air. Soluble at 15° C. (59° F.), in 25.6 parts of water, and in 15 parts of alcohol; also soluble in 10 parts of glycerin. Addition of hydrochloric acid increases its solubility in water. When heated to 100° C. (212° F.), boric acid loses water, forming metaboric acid (HBO_2), which slowly volatilizes at that temperature. Heated to 160° C. (320° F.), it fuses to a glassy mass of tetraboric (or pyroboric) acid ($\text{H}_2\text{B}_4\text{O}_7$); at a higher temperature the fused mass swells up, loses all of its water, and becomes boron trioxide (B_2O_3), which fuses into a transparent, non-volatile mass. From a boiling solution, boric acid readily volatilizes. The solution in alcohol or glycerin burns with a flame enveloped with a green-colored mantle"—(U. S. P.).

Boric acid has feeble acid properties. It dissolves in the essential oils. "An aqueous solution (1 in 50) of boric acid colors blue litmus paper red, but yellow turmeric paper brownish-red after drying, even when the solution had been acidulated with hydrochloric acid; this brownish-red color is changed to bluish-black by ammonia water. A 2 per cent aqueous solution of the acid should not be precipitated by barium chloride T.S. (absence of sulphate); silver nitrate T.S. with nitric acid (absence of chloride); ammonium sulphide T.S. (lead, copper, iron, etc.); ammonium oxalate T.S. (calcium); or sodium phosphate T.S. and ammonia water (magnesium). No odor of ammonia should be evolved by heating the acid with potassium or sodium hydrate T.S. In a solution of 1 Gm. of boric acid in a mixture of 1 Cc. of hydrochloric acid and 49 Cc. of water, 0.5 Cc. of potassium ferrocyanide T.S. should not at once produce a blue color (limit of iron). A fragment heated on a platinum wire (thoroughly cleansed by washing and heating until it no longer colors the flame), should not impart to the non-luminous flame a persistent yellow color (absence of sodium)"—(U. S. P.).

Action, Medical Uses, and Dosage.—Though used for the destruction of roaches and other insects, boric acid is generally without any marked action on the higher animals. When absorbed, however, from local applications to raw surfaces, or when injected into the pleural sac of man (5 per cent solution) death has resulted preceded by vomiting, singultus, and collapse, some cases exhibiting general erythema of the skin and diarrhoea, followed by bloody vomiting and increased activity of the kidneys, finally ending in complete renal inaction and death.

Applied to the cutaneous surface boric acid is wholly unirritating, and when an antiseptic and antipytic dressing for wounds is demanded it may be used with advantage. It is of value as a dressing for burns and scalds, a petrolatum ointment being the preferred form. Cloths dipped in a saturated solution may be continuously applied to dog bites. Certain aphthous conditions are benefited by its local application, and Prof. Locke directs for badly ulcerated diphtheria: R Boric acid 1 part; glycerin 30 parts. Mix. Sig. Apply locally. Ozena and other forms of nasal catarrh, as well as pharyngitis, are benefited by it.

Owing to the property of correcting fetor possessed by this drug, it has yielded efficient results in modifying the fetid eructation accompanying fermentative stomach disorders, and by its chemical action it corrects excessive alkalinity of the renal secretions resulting in ammoniacal urine and its consequent cystic irritation. Mucopurulent secretions, such as accompany gonorrhœa, vaginitis, cystitis, nasal catarrh, etc., are in a measure controlled by a solution of this acid. It is also one of the most efficient remedies for fetid perspiration, particularly of the axilla and feet. Its main use, however, outside of its application to wounds, has been in ophthalmic and aural practice. Though often an abused drug, if properly used in well selected cases it gives admirable results. It is signally useful in irritable eyes with redness and itching, and for the various forms of conjunctivitis, with much secretion, it gives excellent results. Where the conjunctival surfaces

are thickened and velvety and the secretions copious and watery, the acid in impalpable powder may be dusted upon the parts, though the practice should not be long continued lest unpleasant dryness of the membranes should result (Foltz). *Phlyctenular conjunctivitis* and *corneal ulceration* are well treated in the same manner. For *ciliary blepharitis* an ointment of from 5 to 10 grains of boric acid to 2 drachms of petrolatum forms a soothing and effectual application. The ointment has also been successfully applied in certain *skin affections*. The acid is combined with Lloyd's ergot by Foltz (*Dynamical Therapeutics*) in all conjunctival disorders as follows: From 10 to 30 drops of the ergot are added to a solution of 6 grains of boric acid in 1 fl̄ of water; of this 2 drops are instilled in the eye every 2 or 3 hours. In ear diseases this acid has proved of great service. In *purulent inflammation of the middle ear* with turgid membranes and slight discharge, apply it with ergot; if the membranes be pallid combine it with iodoform; if a moderately profuse, thin, acrid pus be discharged, calendula and boric acid give the best results. For *polypoid growths* and *granulations* it may be combined with salicylic acid and dusted upon the parts. In *otorrhœa* the powder should be frequently dusted upon the parts, and excellent results have attended this procedure. The internal dose of boric acid is from 1 to 15 grains; for external use from a 1 per cent to a saturated solution, according to the parts to which it is to be applied.

Specific Indications and Uses.—*Locally*: Wounds; conjunctival disorders with velvety, thickened membranes and profuse secretion; *otorrhœa*; fetid perspiration. *Internally*: Fetid eructations, ammoniacal urine.

Related Product.—GLACIALIN. This is said to be a mixture of boric acid (8), biborate of sodium, and sugar of each (3) and glycerin (2) parts, and is employed to preserve foods and is used as an antiseptic.

ACIDUM CARBOLICUM (U. S. P.)—CARBOLIC ACID.

FORMULA: C_6H_5HO . **MOLECULAR WEIGHT:** 93.78.

SYNONYMS: *Phenol*, *Phenic acid*, *Phenylic acid*, *Acidum phenicum*, *Acidum phenylicum crystallisatum*, *Phenylic alcohol*, *Hydrate of phenol*.

Origin, History, and Preparation.—Carbolic acid was discovered in coal-tar in 1834 by Runge, who gave it the name it now bears. It belongs to the class of phenols, substances closely allied to the alcohols, but having pronounced acid properties. Phenols are those derivatives of aromatic hydrocarbons, such as benzene, naphthalene, etc., in which hydroxyl replaces the hydrogen of the hydrocarbon ring. They form salts with alkalis, which are called phenates, or carbolates, or phenol alkalies, e.g., phenol potassium. The greater portion of the pure carbolic acid now in use comes to us from England and Germany. A large quantity of crude, and some nearly pure phenol is now made within the United States. Commercial carbolic acid is derived from the distillation of the heavy oil from coal-tar, known as *dead oil*, which when heated between 150° C. (302° F.) and 200° C. (392° F.) passes over as a brown oil and is then subjected to two rectifications, the resultant product being *crude carbolic acid* (*acidum carbolicum crudum*, or *impurum*). This product is then converted into sodium or potassium phenol by agitating it with a warm concentrated solution of caustic soda or potash. A solid crystalline mass results from which the supernatant oily liquid, containing hydrocarbons and other impurities, may be poured off. The sodium or potassium phenate is then subjected to a heat of 170° C. (338° F.), and a portion of the empyreumatic impurities is driven off, the remainder being separated by dissolving the salt in 10 parts of water. Hydrochloric acid is then added to supersaturation, upon which the carbolic acid separates in an oily condition. After washing the phenol with a saturated solution of sodium chloride, it is dried over calcium chloride, and distilled. That which distills over between 180° and 190° C. (336° and 374° F.) is then subjected to a low temperature, when crystals are deposited, and after being separated from the adherent mother-liquor, are dried by expression. If further purification is desired, it may again be mixed with an alkali and treated as before. By this process cresol and several other impurities (to which, however, the value of phenol is largely due) are separated.

Prof. Church (1871) proposed the preparation of pure carbolic acid by dissolving the nearly pure commercial crystals in 20 parts of water, by which a portion of it is dissolved, the undissolved portion retaining the foreign matter. Decant or siphon off the clear, aqueous solution, saturate it with sodium chloride when the phenol rises to the top as an oily layer, which may then be freed from its water by distillation with lime, when crystals having a faintly aromatic odor are obtained.

Synthetic Carbolic Acid.—A synthetic carbolic acid is now prepared, and has the advantage of being free from cresols and other homologous products. Benzene-sulphonic acid is first produced by moderately heating a mixture of fuming sulphuric acid and benzene. Neutralization with potassium carbonate then converts the acid into potassium benzene-sulphonate, and this when fused with caustic potash in large excess, yields potassium phenol and potassium sulphite. The phenol is then liberated from the potassium phenol and purified by distillation.

Description.—Carbolic acid occurs in commerce in two forms which are described in the Pharmacopœia as follows:

I. **ACIDUM CARBOLICUM CRUDUM (U. S. P.).** *Crude carbolic acid (Acidum carbolicum impurum).*—"A liquid consisting of various constituents of coal-tar, chiefly cresol and phenol, obtained by fractional distillation" (U. S. P.). "It is a nearly colorless, or reddish, or brownish-red liquid, of a strongly empyreumatic and creosote-like odor; having a benumbing, blanching, and caustic effect upon the skin or mucous membrane; and gradually turning darker on exposure to air and light. The aqueous solution of crude carbolic acid has a slightly acid reaction on litmus paper. In an aqueous solution of the acid, bromine water produces a white precipitate. Crude carbolic acid should not be soluble in less than 15 parts of water at 15° C. (59° F.), and the aqueous solution should not have an alkaline reaction (absence of alkalies). If 50 volumes of the acid be thoroughly agitated with 950 volumes of water, in a capacious vessel, on allowing the mixture to separate, the undissolved portion should not exceed 5 volumes, or 10 per cent by volume of the acid (limit of other less soluble constituents of coal-tar)"—(U. S. P.).

II. **ACIDUM CARBOLICUM (U. S. P.).** *Carbolic acid (Phenol).*—"A constituent of coal-tar, obtained by fractional distillation, and subsequently purified. Carbolic acid should be kept in dark, amber-colored, well-stoppered vials. Colorless, interlaced, or separate, needle-shaped crystals, or a white, crystalline mass, sometimes acquiring a reddish tint; having a characteristic, somewhat aromatic odor, and, when copiously diluted with water, a sweetish taste with a slightly burning after-taste. Deliquescent on exposure to damp air. Soluble at 15° C. (59° F.), in about 15 parts of water, the solubility varying according to the degree of hydration of the acid. Very soluble in alcohol, ether, chloroform, benzol, carbon disulphide, glycerin, fixed and volatile oils. Almost insoluble in benzin. When gently heated, carbolic acid melts, forming a highly refractive liquid. It is also liquefied by the addition of about 8 per cent of water. If the acid be liquefied by a gentle heat, and then slowly cooled, under constant stirring, until it is partly recrystallized, the semiliquid mass should have a temperature (remaining stationary for a short time) not lower than 35° C. (95° F.). The acid should have a boiling point not higher than 188° C. (370.4° F.). A lower boiling point, or a higher melting point, indicates a purer or less hydrated acid. When heated upon a water-bath, the acid should be volatilized without leaving a residue. The vapor of the acid is inflammable. Carbolic acid is faintly acid to litmus paper. The aqueous solution of the acid yields, with bromine water, a white precipitate which at first redissolves, but becomes permanent as more of the reagent is added, and appears crystalline when viewed under the microscope"—(U. S. P.).

Perfectly pure carbolic acid is permanent in the atmosphere, but should the so-called pure product contain a trace of water, then it speedily becomes deliquescent. It dissolves sulphur, resin, and copal, forming with the latter a brilliant varnish that remains soft for many months after its application. It is quite freely soluble in hot benzin. It coagulates blood, collodion, and albumen, produces flakes in milk, and destroys the odor of cheese, rendering it soft and unctuous, and added in small amounts to vegetable juices, prevents or checks fermentation. It

combines with the metallic oxides, and reduces several metallic salts, especially those of copper and silver. Its alkaline salts are not very permanent, and have an alkaline reaction; water decomposes its potassium salt; all the soluble carbolates, as well as carbolic acid itself, communicate to pine wood moistened in it, and subsequently dipped in nitric or hydrochloric acid, a black-blue color as it dries. When heated in a sealed tube with ammonia it yields aniline and water. Nitric acid forms picric acid with it. A beautiful orange-colored dye, *aurine*, is made by heating in a glass vessel to 126.6° C. (260° F.) a mixture of carbolic and sulphuric acids, and then slowly and carefully adding to it an amount of oxalic acid nearly equal to the quantity of sulphuric acid used; this having been done, the whole is thrown into cold water, and the resulting green, solid mass is well worked in boiling water to remove all excess of sulphuric acid.

Dr. E. R. Squibb states that pure crystallized phenol or carbolic acid has a sweet and comparatively bland taste, and is nearly odorless, and that the ordinary liquid article of commerce is impure, and owes its azymotic power to another coal-tar principle, *creosol* (see below), which has a smoky, dry, and pungent taste. He is therefore disposed to consider the rejection of *creosol* in the therapeutical article as objectionable, and would prefer the impure article (the commercial liquid carbolic acid, or coal-tar *creosote*) in cases where the azymotic and antiseptic effects are required (*Amer. Jour. Pharm.*, May, 1869, p. 259). Carbolic acid when pure remains clear; but when its homologues are present, *e.g.*, *creosol*, it becomes colored, as with the fluid carbolic acid of commerce. Fabrini asserts that this coloration is caused by the formation of *phenerythen*, a coloring principle, organic in character, and produced by metallic particles suspended in the phenol. This pink, or reddish color, is especially apt to occur in the commercial product on exposure to light and air. This, however, does not impair its medicinal qualities. Carbolic acid is largely employed in fluid form, made by adding to the crystals from 5 to 10 per cent of water, when they readily liquefy and remain fluid. A convenient method is to combine equal parts of carbolic acid and glycerin, which mixture is readily soluble in water in all proportions. Dilute solutions of carbolic acid have a sweetish, smoky taste, followed by a slightly burning sensation. Phenol is largely consumed in the synthetic process of producing salicylic acid and other synthetic compounds, and is extensively employed in the making of dye-stuffs. The pure acid in crystals may be rendered fluid by placing the vial holding it in hot water, being careful, however, to guard against breaking the bottle. The odor of carbolic acid renders it very objectionable with many, but this may be overcome by adding a few drops of oil of lemon to it.

Tests.—"On adding to 10 Cc. of a 1 per cent aqueous solution of the acid, 1 drop of ferric chloride T.S., the liquid acquires a violet-blue color, which is permanent; and on adding carbolic acid either to albumen or to collodion, coagulation takes place (difference from *creosote*). One volume of cold, liquefied carbolic acid (rendered liquid by the addition of 8 per cent of water) forms, with 1 volume of glycerin, a clear liquid which is not rendered turbid by the addition of 3 volumes of water (absence of *creosote* or of *creylic acid*). If 0.039 Gm. of carbolic acid be tested by the method immediately following, there should be required for its complete conversion into tribromophenol not less than 24 Cc. of decinormal bromine V.S. (each Cc. of the volumetric solution corresponding to 4 per cent of absolute phenol)"—(*U. S. P.*).

"VALUATION OF CARBOLIC ACID.—Dissolve 1.563 Gm. of carbolic acid to be valued, in a sufficient quantity of water to make 1000 Cc. Transfer 25 Cc. of this solution (containing 0.039 Gm. of the acid) to a glass-stoppered bottle having a capacity of about 200 Cc. add 30 Cc. of decinormal bromine V.S. (which is 5 Cc. more than would be required if the carbolic acid in solution were absolute phenol, the excess being added to promote the formation and separation of tribromophenol), then 5 Cc. of hydrochloric acid, and immediately insert the stopper. Shake the bottle repeatedly in the course of half an hour, then remove the stopper just sufficiently to introduce quickly 5 Cc. of a 20 per cent aqueous solution of potassium iodide, being careful that no bromine vapor escape, and immediately stopper the bottle. Shake the latter thoroughly, remove the stopper and rinse it and the neck of the bottle with a little water, so

that the washings may flow into the bottle, and then add, from a burette, decinormal sodium hyposulphite V.S., until the iodine tint is exactly discharged, using towards the end a few drops of starch T.S. as indicator. Note the number of Cc. of decinormal sodium hyposulphite V.S. consumed. Deduct this from 30 (the number of Cc. of bromine V.S. originally added), and multiply the remainder by 4. The product will, approximately, represent the percentage of absolute phenol in the carbolic acid tested"—(U. S. P.).

Action and Toxicology.—Carbolic acid is destructive to insects and the lower forms of life. Locally applied to the skin of man it produces a burning sensation, followed by numbness, its continued action being anæsthetic. A peculiar whitish eschar is formed, which eventually becomes brown, and may terminate in a slough. To the taste it is hot, pungent, and sweetish. By coagulating the albumen of the tissues it produces, when swallowed accidentally or with suicidal intent, corrugated, whitish patches upon the lips, fauces, œsophagus, orifices, and folds of the stomach. It readily diffuses itself into the blood, producing pronounced effects upon the nervous system, as vertigo, pallor, and pupillary contraction. The circulation becomes feeble, the pulse either very rapid or abnormally slow, and breathing is impeded. Fatal results have been produced by injections of even weak solutions of this acid into the serous cavities, and many cases of death are on record produced by absorption from dressings of carbolic acid applied to open wounds. When a fatal dose has been swallowed the individual quickly becomes profoundly unconscious, the skin is cold and livid, breathing becomes stertorous, the heart's action gradually grows feebler, and death ensues from respiratory paralysis. Vomiting is sometimes produced in man, and convulsions occasionally. Carbolic acid is principally eliminated by the kidneys, and the dark coloration of the urine produced by it should be a signal to stop its administration. Constant phenomena of poisoning by this agent are a minutely-contracted pupil, and the dark, greenish, blackish, or smoky hue of the urine. After death the blood shows imperfect coagulability.

Carbolic acid poisoning is antidoted by solution of sodium sulphate (Glauber's salt). All the soluble sulphates are chemically antagonistic. Albuminous and demulcent drinks should be freely administered and the stomach-pump employed. In cases of corrosive poisoning emetics should not be employed where the tissues are much destroyed, on account of the danger of rupturing the stomach. The stomach-pump is preferable. Atropine, carried to the extent of maintaining dilatation of the pupils, is said to be physiologically antagonistic, and should be employed to prevent collapse. Saccharate of lime, probably one of its best antagonists, may be used as a chemical antidote if sulphate of sodium is not at hand. Oils should never be given, as they increase the solubility of the poison. On the other hand, some recommend olive oil until the patient vomits. Or after the use of the stomach-pump it is advised to administer freely of olive or sweet almond oil, to which a little castor oil has been added. A mixture of flour and water and soap are recommended highly as simple antidotes. Solution of sodium or magnesium sulphate should be continued in small doses for several days to antidote any remaining traces of the acid.

Among other toxic symptoms the following may present: strangury, stupor, vertigo, tinnitus aurium, deafness, formication, profuse perspiration, frothy salivation, a reduction of temperature, a characteristic intoxication and general anæsthesia. The fatal dose of carbolic acid is not known. A six-months' old babe was killed by a quarter teaspoonful of the glycerin solution (1 to 5). An adult has been killed by 80 grains, while again individuals have recovered from large doses—6 drachms (30 per cent) in one case and 1½ ounces of the solution in another. The time necessary to kill ranges from 3 minutes to 4 hours.

Medical Uses and Dosage.—Carbolic acid is an antiseptic and azymotic, being a violent poison for vegetables and inferior organic bodies; it checks fermentation, prevents the formation of mold in vegetable infusions or juices, and preserves animal tissues from decomposition. It exerts an escharotic influence upon animal tissues when applied, undiluted, producing considerable pain, followed after a time by a white appearance of the part, severe inflammation, and after 15 or 20 days, by an exfoliation of the epidermis. It should never be employed in an undiluted state for ordinary use. But as a caustic, acting

superficially, it may be used in *indolent* or *gangrenous ulceration*, *hemorrhoids*, *fistula in ano*, *syphilitic* and other *warts*, *soft chancre*, *carbuncle*, and rarely in *diphtheria* and *malignant sore throat*. Its antiseptic power renders it very valuable as a local application in surgical cases accompanied with purulent, offensive, or other discharges; it is also said to facilitate the healing of *wounds* by the first intention. Two to three parts of carbolic acid to 100 parts of water, applied to *necrosis*, *gangrenous* and other *ulcers*, modifies the suppuration and favors cicatrization. The cases to which it is best adapted are those in which the tissues are full and relaxed. It is contraindicated, as a rule, where the parts are dry, shrunken, or contracted. It is particularly applicable, as a local application, to gangrenous parts where the debilitation is dependent upon diabetes or chronic alcoholism. As a stimulating and deodorizing ointment for *old sores* and *ill-conditioned ulcers*, Prof. Locke recommends: R Carbolic acid ʒi ; basilicon ointment ʒxvj . Mix. Apply. Its principal use, however, has been in the treatment of certain cutaneous affections, especially those due to, or accompanied with, animal or vegetable parasitical formations, as in *pediculi*, *scabies*, *eczema*, *lepra*, *impetigo*, *tetter*, *pityriasis*, *lichen*, *psoriasis*, *erythema*, *dermatitis*, etc., in which cases it is used in combination with glycerin, 1 part of acid to 4, 6, 8, or more parts of glycerin. A very excellent application for several cutaneous affections is 1 part of carbolic acid to 4 parts of acetic acid and 15 parts of water. A weak solution of the acid in water forms an excellent topical agent for itching, whether due to *urticaria* or the skin affections above noted, to jaundice or to the parasitic skin affections. In fact, it is particularly useful in *scabies*, *ringworm*, and *tinea versicolor*, *favus* and "*barbers' itch*." Prof. Bloyer states that he has never failed to cure the latter trouble with it. If desirable to combine it with sulphur he recommends the following: R Carbolic acid gr. v.; sublimed sulphur ʒss ; camphor gr. x; ung. zinci ox. ʒi . Mix.

A dilute aqueous solution of carbolic acid (about 1 to 200) employed as an injection will destroy *worms* in the rectum; and injected into the vagina has proved beneficial in *leucorrhœa*, *vulvitis* in the young, *endometritis*, *blenorrhœa*, *gonorrhœa*, *gleet*, *fetid discharges*, and *ulceration of the os uteri*. A solution of from 2 to 5 grains to a fluid ounce of water, injected into the urethra, has cured *gonorrhœa*. It has proved decidedly useful in *boils*, *whitlows*, and *abscesses*, injecting it into the cavity of these after the pus had been discharged. Care must be had not to poison by absorption. For the purpose of anæsthetizing *abscesses* it may be applied to the crown of the lesions, when the pent-up pus may be painlessly liberated and at the same time deodorized. An excellent treatment for *malignant pustule* or *carbuncle* is to first anæsthetize the surface, and then incise and thoroughly curette the cavities, and finally destroy the remaining slough by another immediate application of the acid. This treatment is said to give but little pain and no shock, and is attended with neither hemorrhage nor putrid absorption. *Hydrocele* and *hemorrhoids* have been treated by injecting from 15 to 20 minims of a 25 per cent solution. For the former *thuja* is better, while for the second carbolic acid yields as fair results as other injection-fluids. As a post-partum vaginal douche carbolic acid is largely employed by midwives and by many physicians.

In chronic *purulent conjunctivitis* a solution of equal parts of carbolic acid and glycerin, applied to the palpebral conjunctiva, has promptly arrested the disease. An ointment (carbolic acid grs. xij to petrolatum ʒii) has been serviceable in *trachoma*, and the *ulcers* attending *traumatic keratitis* may be cauterized with this acid. A 2 per cent solution is effectual in *ophthalmia neonatorum*, though not so safe as boric acid, and the pure acid applied to the stump after *evisceration of the eye-ball* appears to relieve the pain and stop hemorrhage (Foltz). *External otitis* with much swelling may be treated with a tampon soaked in the glycerin solution (1 in 10) to relieve the pain and reduce the swelling, while in *tympanic hyperemia*, without effusion, the 15 per cent glycerin solution gives marked relief from pain. A solution of the acid in water, used as a wash immediately following coition, is supposed by many physicians to effectually prevent any consequent chancre. One part of carbolic acid to 100 parts of water, injected into the bladder, has been successful in *cytitis*, in which from prostatic hypertrophy or urethral stricture the urine putrefies in the bladder with formation of zoophytes, *Penicillium glaucum*, etc. In *burns* and *scalds* carbolic acid affords immediate relief, also in *bites* and *stings of insects*. In these accidents it has been neglected. One part of the acid

to 6 or 7 or even 16 parts of olive oil, applied with lint, and covered with tin-foil or oil-silk, will be found very useful in cases of severe burns or scalds.

Locally applied pure carbolic acid destroys *warts* and *condylomata*, and is of some benefit in *cancerous affections*. The glycerin solution (1 in 4), or equal parts of the acid and glycerin, may be applied to *uterine cancer* to relieve pain and control fetor. That strength should be used which best controls pain. In *epithelioma* it has been used full strength to destroy the growth. Warm the crystals to deliquescence and thoroughly apply to the bottom of the growth with a pine pencil. For *rodent ulcers*, *poisoned wounds*, and *phagedenic chancre* it may be used full strength, while to *indolent ulcers* and *bubo* the glycerin solution (1 in 4) should be applied. *Toothache* from decayed teeth with exposure of the nerve pulp is quickly relieved by inserting the acid upon cotton into the cavity of the tooth and retaining it there.

An inhalation of carbolic acid is of value in *pulmonary gangrene*. As a 5 per cent spray it may be serviceable in *coryza*, *putrid bronchorrhœa*, *influenza*, *nasal catarrh*, *ozena*, *ulcerated sore throat*, *chronic pharyngitis*, *pertussis*, *chronic bronchitis*, and has even been recommended in *phthisis pulmonalis* as an auxiliary means of treatment; for this latter purpose a grain or two to an ounce or two of water is the strongest solution that should be used. Its use must be discontinued if faintness, giddiness, or trembling, with a weak pulse, should follow its inhalation. It is in some of these conditions that *Dobell's solution* (which see) containing this acid has such a wide application. *Offensive breath* arising from oral, faucial, or dental troubles or from diphtheria is corrected by this agent. It has proved very valuable in dissections, the difficulty of preserving the subject being effectually overcome by injecting carbolic acid mixed with water, and it does not materially affect the appearance of the tissues. One drachm of carbolic acid dissolved in 1 fluid drachm of alcohol and 2 fluid ounces of water, and sprinkled around a sick chamber by means of a spray instrument or otherwise, will be found a valuable disinfectant. Altogether it is a very efficient and valuable remedy, and in all cases the greatest dilution possible should be used that will have the desired effect, that the danger of toxic symptoms from absorption may be avoided.

Internally, pure, crystallized carbolic acid has been advantageously employed in *obstinate vomiting*, in *sarcinæ ventriculi*, *gastric pain* following meals, *flatulency*, *diarrhœa* from eating articles causing fermentation, *scarlatina anginosa*, *typhoid fever*, low grades of *pneumonia*, *bladder diseases*, *cholera*, *cholera morbus* and *cholera infantum*, *tapeworm*, and *diabetes* dependent upon liver disorders, *offensive breath*, etc. It is not, however, to be indiscriminately used, and is always contraindicated by a pinched and contracted condition and where the tongue is dry, long and pointed. It is specifically applicable (as pointed out by Prof. Scudder) where the tongue is broad and moist and the odor putrescent or cadaverous. On the whole it is none too desirable as an internal remedy, but when so administered the dose should be small. *R*. Glycerin solution of carbolic acid (1 in 5), gtt. v to xxx; aqua flziv. Mix. Dose, a teaspoonful every 2 or 3 hours. The dose of the glycerin solution of carbolic acid (carbolic acid 1 part, glycerin 4 parts) is from 1 to 10 drops well diluted. One drop, largely diluted, is the usual dose of pure carbolic acid. Locally any attenuation to full strength as indicated.

Specific Indications.—*Internal use*: "A broad, moist tongue; there is a cadaverous odor of the breath." *External use*: "Fullness and relaxation of tissues; whenever there is retraction, shrinking, and dryness it will prove harmful"—(Scudder).

Related Compounds and Preparations.—LIQUEFIED PHENOL. Carbolic acid, to which 10 per cent of water or glycerin has been added, the former being more generally preferred.

PHENOL WATER, Carbolyzed water.—There are several formulæ for the preparation of *aqua carbolyzata*. The German *Pharmacopœia* directs a solution of carbolic acid (liquefied), 33 parts, in distilled water, 967 parts, thus containing about 3 per cent by weight of the pure acid. The French *Codex* directs two carbolyzed waters, one for internal use containing 0.1 per cent of phenol, and one for topical use containing 1 per cent. Used chiefly as a gargle and as a lotion in *skin diseases*.

SULPHO-CARBOLIC ACID, Sulphonic acid, Aseptol, Sozolic acid, Sulphophenol, Orthophenol-sulphonic acid. Formula: $C_6H_4.OH.SO_3H$. Molecular weight: 173.64. Density: 1.45. Two or more sulphophenols result from the interaction of sulphuric and carbolic acids. The ortho-compound may be produced at a low temperature; the para-compound at a high heat. Sulphophenol forms small needle crystals, which are deliquescent, but is usually found as a heavy,

syrupe fluid, of an amber or reddish color, and an odor recalling that of phenol. Water, glycerin, and alcohol dissolve it. *Commercial cresol* contains about 33 per cent of the ortho-acid, and is a sub-caustic liquid of a pale-yellow color. This drug has been used chiefly as an antiseptic in *rye, skin, and bladder diseases*. Benefit is said to be derived from its administration in *pharyngitis* and *laryngitis* of a diphtheritic character. It is recommended to be given largely diluted. It has been locally employed in *pyorrhæa* and in *gingivitis*, using from 1 to 8 or 10 per cent solutions.

LISTER'S CATGUT LIGATURES, Carbolated catgut.—Preserved in carbolated olive oil (1 part of phenol to 5 parts of oil). This is prepared by immersing catgut (200 parts) in a freshly-prepared mixture of phenol (200 parts) and a weak solution of chromic acid in water (1 part in 4000). The catgut should be macerated 48 hours and then placed in the carbolated oil.

CHLOROPHENOL, Monochlorophenol, Chlorophenol.—Formula: $C_6H_4Cl.OH$. This very volatile liquid is prepared by acting upon carbolic acid (phenol), at a very low temperature, with chlorine gas. It was originally introduced from Italy as a remedy for *tubercular phthisis*. It is heavier than air, yet volatilizes with great ease, and so penetrating are its dense fumes that the pulmonary air passages are readily filled by them. Antiseptic, as well as antitubercular properties are attributed to it. It is usually employed by inhalation, and has been used in *tubercular troubles, æsena, bronchitis, laryngitis, etc.* Locally, *discharging ulcers, wounds, and glands* have been treated with it. An inhalation preparation has been employed, consisting of an alcohol-eugenol-menthol mixture 3 parts, chlorophenol 7 parts. From 10 to 30 drops are to be daily inhaled.

PHENO-SALYL.—This is thought to be a mixture formed by melting together 9 parts of phenol, 2 parts of lactic acid, 1 part of salicylic acid, and $\frac{1}{10}$ part of menthol, the latter being added just as the acid liquefies. It is claimed for this preparation that its antiseptic qualities far exceed those of phenol or of salicylic acid. It was introduced by De Christmas.

ACIDUM CARBOLICUM IODATUM (N. F.), Iodised carbolic acid (Phenol iodatum, Iodised phenol).—*Formulary number, 4:* "Iodine, reduced to powder, 20 grammes (20 Gm.) [309 gra.]; carbolic acid, 60 grammes (60 Gm.) [2 oz. av., 51 gra.]; glycerin, 20 grammes (20 Gm.) [309 gra.]. Introduce the iodine into a flask, add the carbolic acid, previously melted, then the glycerin, and digest the mixture at a gentle heat, frequently agitating, until the iodine is dissolved. Keep the product in glass-stoppered vials in a dark place."—(*Nat. Form.*).

CARBASUS CARBOLATA (N. F.), Carbolized gauze.—*Formulary number, 17:* "Resin, in coarse powder, 40 grammes (40 Gm.) [1 oz. av., 180 gra.]; castor oil, 5 grammes (5 Gm.) [77 gra.]; carbolic acid, 10 grammes (10 Gm.) [154 gra.]; alcohol, 225 grammes (225 Gm.) [7 oz. av., 410 gra.]; gauze muslin, a sufficient quantity. Dissolve the resin, castor oil, and carbolic acid in the alcohol. Immerse in the mixture loosely folded pieces of gauze muslin, allow them to become thoroughly saturated, then take them out and press out the excess of liquid until the weight of the impregnated gauze amounts to one hundred and seventy grammes (170 Gm.) [6 oz. av.] for every one hundred grammes (100 Gm.) [3 oz. av., 231 gra.] of the original fabric. Spread out the pieces horizontally, and, as soon as the alcohol has nearly all evaporated, fold and wrap the pieces in paraffin paper, and preserve them in air-tight receptacles. The impregnated gauze, when dry, contains about 2.5 per cent of carbolic acid. *Note.*—The most suitable brands of gauze muslin, for making carbolized or other antiseptic gauze, are those known in the market as 'Stillwater' or 'Lehigh E'."—(*Nat. Form.*).

ACIDUM PHENYLO-BORICUM, Phenylo-boric acid.—This white powder is said to be a powerful germicide, preventing putrescence in less than a 1 per cent solution. It is very sparingly dissolved by water. Locally, it has been used on *venereal sores*, and is reputed active against the *cholera* and other like bacilli.

BORO-PHENOL.—A combination of phenol and borax, having a not unpleasant odor, and wholly dissolved by water. To be used as a disinfectant in all cases in which phenol is useful.

TRICHLORPHENOL ($C_6H_2Cl_3.OH$).—This is the chief substance produced when chlorine is made to act upon carbolic acid. It forms in needle crystals readily soluble in alcohol and ether. A glyceride containing from 5 to 10 per cent of trichlorophenol has been painted twice daily on an *erysipelatous eruption*, with asserted benefit. Laurent discovered this body, and Yurinsky, of St. Petersburg, introduced it into medicine.

CRESOLS (C_7H_8O) or ($C_6H_4.CH_3.OH$).—The cresols may be obtained by the interaction of caustic potash and toluene sulphonic acid, though they are most generally obtained from that coal-tar distillate which passes over between 200° and 210 C. 392° and 410° F.). They are present also in beech-wood tar, and when present in carbolic acid, as they often are, the boiling point of the latter is raised, while the fusing point is lowered by them. Theory indicates the existence of three cresols, viz.: *ortho-cresol, meta-cresol, and para-cresol*. The second is a dense liquid; the other two form colorless, prismatic crystals possessing the odor of phenol. The second has a boiling point at 201° C. (393.8° F.), but even at a very low temperature, —80° C. (—112° F.), does not become solid. The first fuses at 31° (87.8° F.), has a boiling point at 185° C. (365° F.), and is converted into salicylic acid by long continued heating with caustic potash. The third has its fusing point at 36° C. (96.8° F.), and its boiling point at 198° C. (388.4° F.), and if heated with potassium hydroxide becomes paroxy-benzoic acid. None of these forms possess toxic qualities to the extent of that possessed by carbolic acid, and all of them have powerful disinfectant properties and are destructive to low forms of life. Cresol (cresylic acid) has greater antiseptic properties than phenol (Delplanque), and diffused in the sick room has a palliative effect in *whooping-cough*. Several derivatives or compounds of the cresols are now employed, chiefly as external remedies. Of these may be mentioned the following:

1. **LYSOL.**—This product contains cresols to the extent of about 50 per cent, and is said to be produced by boiling tar-oils with fats and alkalis, or saponifying them with alcohol. It

is a transparent, brown, oily-appearing fluid, having a faintly aromatic or creosotic odor. Its density is 1.042. It is dissolved by alcohol, glycerin, chloroform, benzine, carbon disulphide, and water, with the latter forming a clear solution, producing a soap-like frothiness. Its saponaceous character causes it to impart a slipperiness to instruments immersed in it, thus making them difficult to handle. Though much stronger than carbolic acid, it is far less poisonous. It is largely employed in surgical and gynecological practice for its general antiseptic effects, as well as in various skin disorders, *lupus* in particular. It has been proposed as a gargle for *offensive breath* and as a local application to *diphtheritic ulcerations*. It has been employed in conditions presenting *mucorrhœa*, as *leucorrhœa*, *gonorrhœa*, *nasal discharges*, *cholera morbus*, *dysentery*, etc. Sick-room utensils and surgical appliances are deodorized and disinfected by it. For local application a 1 to 5 per cent solution is directed; for internal administration solutions of $\frac{1}{4}$ of 1 per cent are employed.

2. **SAPROL.**—This is an inflammable mixture of the cresols in crude condition, together with petroleum, hydrocarbons, and pyridine bases. Even in 1 per cent solution it is said to be a powerful antiseptic.

3. **CREOLIN.**—Creolin is a deep-brown, syrupy fluid having an alkaline reaction and a density ranging from 1.040 to 1.080. It is obtained from coal-tar by freeing the latter of its carbolic acid. It mixes in all proportions with absolute alcohol, fixed oils, and chloroform, is not dissolved by wood alcohol, and when mixed with water a milky, turbid liquid is produced. There are two chief preparations of creolin on the market, Pearson's (from England), and Artmann's (from Germany). The former is perfectly soluble in ether and in the cold, and particularly in the presence of ice, deposits naphthalene in hard, white crystals; the second is but sparingly soluble in ether, and contains less phenol than the English product. Both contain phenols in combination with soda, by the means of which the hydrocarbons present are probably held in solution. Pearson's contains 60 per cent of hydrocarbons; Artmann's 85 per cent. While these preparations are considered non-toxic, it is nevertheless true that poisonous symptoms, and even death have been attributed to their use, even in small amounts. A 2 per cent solution is charged with causing death when used as a post-partum intra-uterine douche, and 30 drops by mouth is said to have caused in an infant inflammation of the glottis, followed by death. In excessive doses it has produced unconsciousness, vomiting, and thirst, but no pain, and the urine was bloody and albuminous, with the odor of carbolic acid. Scarlatinoid and eczematous eruptions have been produced by it. A 2 per cent solution in doses of a drop or two produces a burning sensation in the mouth and naso-pharynx. It is, however, said to be a very effectual deodorizer—even of more value than carbolic acid. Hard rubber and gutta serena are attacked by it, while such effects are not apparent on metallic instruments, though all instruments are rendered slippery and difficult to handle when immersed in its solution. It checks in a measure *ammoniacal fermentation of the urine*, and in a $\frac{1}{4}$ per cent solution has been used to wash out the bladder in *ammoniacal cystitis*. A 1 to 2 per cent solution as a wash or on gauze compresses, is reported effectual in subduing pain, checking bleeding, and limiting suppuration. Fermentative changes are checked by it. *Putrefaction* from retained placenta, etc., has been overcome by from 1 to 2 per cent solutions locally, though as before stated, death is reported to have resulted from its use as an intra-uterine douche. It may be applied on a vulvar compress to deodorize puerperal discharges. *Gangrenous* and other *foul ulcers, wounds*, etc., may be dressed with a weak solution, though the healing of open, fresh wounds is said to be somewhat retarded by it. Skin affections, such as *impetigo*, *eczema*, etc., have received benefit from the ointment (2 per cent), while a solution of 1 part of creolin in from 10 to 20 parts of alcohol is recommended for *parasitic skin diseases*. *Leucorrhœa*, *gonorrhœa*, *acute* and *chronic dysentery* are benefited by injections of a weak solution, while a spray (1 in 500) has given fairly good results in *follicular tonsillitis*, *ulcerations of the pharynx*, and fetid conditions of the nasal passages. The *cough of consumption* has been somewhat palliated by such atomization. It has been used in ear and eye affections, but such a procedure is not to be commended, and it is specially contraindicated in keratitis with involvement of the iris and in chronic conjunctivitis. The internal use in *gastro-intestinal disorders* with fermentation, has received some praise. The internal doses are from 1 to 5 minims, preferably in capsules; externally, an aqueous mixture, ointment, and gauzes of from 1 to 2 per cent strength.

4. **SOZAL**, *Aluminum sulphocarbolate* ($Al_2[C_6H_4OHSO_3]_6$) so-called, is produced by the union of paraphenol-sulphonic acid with aluminum as the base. It may be directly prepared by acting upon aluminum hydroxide with phenol-sulphonic acid. It occurs as a granular powder composed of aggregations of small crystals. To the taste it is very astringent, and has a faint odor of carbolic acid. Water, alcohol, and glycerin dissolve it, forming permanent solutions. It is employed where an astringent possessing antiseptic properties is required.

5. **SOLUTOL.**—A sodium cresylate solution of cresol, one-fourth of which is in a free condition, the remainder being in combination with sodium. Solutol is a powerfully disinfectant and anti-putrefactive agent, being used for disinfecting water-closets, excrements, bedding, sputa, etc. It has caustic properties, and is said to be useful as an anatomical preservative.

6. **SOLVROL.**—A concentrated, neutral, aqueous solution of cresol prepared by the intervention of sodium cresotinate. It has scarcely any odor, and is considered superior to carbolic acid as a disinfectant, being about 4 times as active. It is not caustic, and is free from the greasiness which some of the other cresol compounds, such as lycol and creolin, possess. One-half per cent solutions of it scarcely irritate. It is used locally, being well adapted for surgical purposes.

ACIDUM CARBONICUM.—CARBONIC ACID.

FORMULA: $\text{CO}_2=\text{OCO}$. MOLECULAR WEIGHT: 43.89.

SYNONYMS: *Anhydrous carbonic acid, Carbonic anhydride, Carbon dioxide, Carbonic acid gas.*

Source and History.—Carbonic acid gas (the so-called carbonic acid) was observed in mineral waters as early as 1597, by Libavius, who regarded it as a *volatile spirit*; Von Helmont (1577–1644) called it *gas sylvestre*; Hoffman, who noticed its acid properties in natural combination in mineral waters, named it *mineral spirit*; Lavoisier in 1775 determined its composition. In former times this acid was also known as *fixed air*, *acid vapor*, and *aërial acid*. Carbon dioxide is a constant factor in atmospheric air to the amount of about .04 per cent. It is given off by the lungs in respiration and by the skin in perspiration, and taken up by plants in the process of “plant respiration.” It is always formed during the combustion of organic matter, or carbon; it is also a product of vegetable decay, fermentation and decomposition of organic bodies. It is formed also by calcining the native carbonates (as in the making of lime) and by the action of acids on carbonates. It is apt to form in the cellars of breweries and other places where large quantities of organic matter are undergoing fermentation. It exists in combination in many minerals and also in many mineral springs. The German Spring at Nauheim is said to liberate 3000 pounds of carbon dioxide daily. It is one of the constituents of the deadly “choke damp” of the mines.

Preparation.—Carbon dioxide is prepared on a large scale by treating native carbonates, such as marble, etc., with diluted sulphuric acid. For laboratory purposes it may be conveniently prepared by treating pieces of marble with diluted chlorhydric acid.

Description.—Carbonic acid, so-called, is not strictly an acid, but is rather to be considered as carbonic anhydride, which, when combined with a molecule of water, forms carbonic acid (H_2CO_3). Thus: $\text{CO}_2 + \text{H}_2\text{O} = \text{H}_2\text{CO}_3$. True carbonic acid (H_2CO_3) does not exist in a free condition, but is usually found in combination with water, as in mineral springs, and by its combination with bases gives rise to the native carbonates, the calcium carbonate especially forming the backbone of the earth. It is a weak, bibasic acid. The acid carbonates (bicarbonates), liberate carbon dioxide when heated. Soda water, the summer beverage, is a solution of carbonic acid (H_2CO_3) in water (see *Aqua Acidi Carbonici*).

CARBON DIOXIDE (CO_2) or *carbonic anhydride*, is an invisible, irrespirable gas, having a faint odor and a sharp, slightly acidulous taste. Its specific gravity is 1.5245, and it is so much heavier than air that it may be poured from one vessel to another; it slightly and transiently reddens litmus; is not combustible, extinguishes most burning bodies, and is reduced to a limpid, colorless liquid under a pressure of 36 atmospheres 0°C . (32°F .), which is practically insoluble in water and in fat oils, but is soluble in all proportions in alcohol, ether, oil of turpentine and carbide of sulphur. When the pressure is removed from the liquid carbonic acid the cold produced by the evaporation of one part is so great that another part freezes, forming a white, snow-like body (solid carbonic anhydride), which is a bad conductor of heat, and has the temperature -64.4°C . (-83.9°F). Mixed with ether and placed under the exhausted receiver of an air pump, Faraday obtained a temperature of 74.4°C . (166°F). The metallic, alkaline, and earthy salts formed with carbonic acid are called carbonates. If a light be introduced into a well, pit, mine, or other place, it will burn dimly or be extinguished if this gas be present, and the air of such place will certainly destroy life if respired. The sparkling and effervescing properties of many kinds of wine, beer, cider, mineral waters, etc., are owing to the presence of carbonic acid gas. When carbon dioxide has accumulated in cellars or other places, so as to render them fatal to animal life, it may be removed by sprinkling about some *aqua ammoniæ*; this combines with the carbonic acid to form carbonate of ammonium, and fresh air rushes in to fill up the space produced by the condensation of the acid.

Action and Medical Uses.—Carbonic acid gas is a narcotic poison inducing cerebral congestion and apoplexy (Taylor). To respire the pure acid is impossible, asphyxiation at once taking place. Diluted with air it is more or less respirable. According to Demarquay, air containing 25 per cent of carbon dioxide may be

respired with but little discomfort; according to others, such proportions would be extremely dangerous. Water impregnated with this gas produces a pungent, prickly sensation in the mouth, nose and fauces, warmth in the stomach, and for a brief time cerebral excitation. Gastric eructations take place, and the gastric secretions are augmented and digestion stimulated. Sensibility of the skin is obtunded in a limb exposed to the gas. Immersion of the body, the head being free, into this gas induced successively prickling and heat of the surface, redness and sweating, quickened heart action, which was afterward retarded, throbbing in the head, dulling of the senses, difficult breathing, borborygmi and colicky pains. Inhaled in toxic quantities, besides some of the symptoms already observed there is a sense of constriction, oppression of the breathing organs, weight in the head, and pressure in the temples, headache, dizziness, singing noises in the ears, tendency to somnolence, great muscular weakness, the patient falling and unable to escape, unconsciousness, the breathing becomes stertorous, then ceases, as does the heart, which at first beats violently. A relaxed and flexible state of the limbs (occasionally rigid, and rarely convulsed) remain, as well as bodily warmth, though the patient appears dead. The countenance is usually leaden-hued, particularly about the mouth and eyes, though occasionally pale and placid, and death ensues. When one recovers, pain and soreness of the body and head remain for many days, while facial paralysis supervenes in some cases. When the amount of gas is great the person is suddenly prostrated and insensible, dropping where found, and totally unable to escape. Death quickly follows unless promptly removed to fresh air.

Carbonic acid gas has been used with success in *scrofulous ophthalmia*, being directed upon the affected part in a small jet; it has also been directed upon the uterus and upper part of the vagina in *dysmenorrhœa* and *ulceration of the cervix*; passed into the rectum it has been found useful in *ulceration of the rectum* and *dysentery*; and in *cancerous* and other *ulcers* it forms a good application. This effect is due to its anæsthetic action. The jet should be continued from 3 to 10 minutes upon the affected part, repeating it 4 or 5 times a day. Formerly, *phthisis*, and *diseases of the bronchiæ* and *larynx* were treated by inhalation of this gas, and it has more recently been employed with asserted success in allaying the suffering and cough in *laryngeal phthisis* and in *whooping-cough*. It formed the basis of the Bergeon (1888) treatment for *phthisis*, a current of the gas being passed through a sulphuretted mineral water twice daily into the rectum, resulting, according to its author, in the prompt alleviation and suppression of all of the active phases of pulmonary consumption. This treatment scarcely attained any popularity with the profession. Iced, effervescing draughts are very serviceable in *obstinate nausea* and *vomiting* due to an irritable stomach. *Flatulence* is relieved by it, and saline medicines are retained by the stomach when administered in the carbonated waters. Undoubtedly the ease and comfort derived from the yeast poultice and other similar applications are due largely to the anæsthetic virtues of the liberated gas. Recent *burns* are said to be promptly soothed and rendered painless by this gas. In accidents arising from its inhalation, remove the patient immediately into the open air, and place him on his back with his head somewhat elevated, and pursue a treatment similar to that named in poisoning by the inhalation of sweet spirit of niter.

ACIDUM CHROMICUM (U. S. P.)—CHROMIC ACID.

FORMULA: CrO_3 . MOLECULAR WEIGHT: 99.88.

SYNONYMS: *Chromic anhydride*, *Chromium trioxide*.

CAUTION: "Chromic acid should be kept in glass-stoppered bottles, and great caution should be observed to avoid bringing it in contact with organic substances, such as cork, tannic acid, sugar, alcohol, etc., as dangerous accidents are liable to result"—(U. S. P.).

Preparation and History.—To 1 volume, or 100 measures, of a cold, saturated solution of bichromate of potassium add $1\frac{1}{2}$ volumes, or 150 measures, of pure sulphuric acid, and allow the mixture to cool in a covered capsule or in a flask; the sulphuric acid unites with the potassium, setting free a deposit of beautiful

deep-red needles of chromic acid. The liquid being drained off, these are laid on a porous brick to dry, covered with a glass bell-jar. According to Prof. J. U. Lloyd, these crystals contain considerable adhering sulphuric acid, which, however, can not easily be separated. As high as 30 per cent of potassium sulphate has been found in some commercial samples (Krauch). According to Krauch, Merck has put forth a chromic acid almost absolutely free from sulphuric acid. It must be preserved in very tightly-stoppered vials. Chromic acid was discovered in 1797 by Vauquelin (who also that year discovered chromium), and was first obtained by the sulphuric acid method by Fritzsche in 1839.

Description.—Chromic acid occurs in beautiful deep, purplish-red, acicular, or quadrangular prismatic crystals, has a metal-like luster, without odor, deliquescent in the presence of moisture, and consequently very soluble in water. Solutions of it vary from brown-red to orange-yellow, according to the degree of concentration. The acid is perfectly anhydrous. It is a powerful oxidizer, and *should never be prescribed with any organic material* (anything that will burn), *or with any inorganic deoxidizer*. "When brought in contact with alcohol, ether, glycerin, and other organic solvents, decomposition takes place, sometimes with dangerous violence"—(*U. S. P.*). It dissolves in ether, but with strong alcohol it becomes explosive, and the alcohol burns. With diluted alcohol it slowly converts the alcohol into aldehyde and acetic acid. It behaves similarly with hydrogen sulphide, sulphurous and arsenous acids, and should not be heated or triturated with glycerin or sweet spirit of niter, as a dangerous explosion may result. On account of the facility with which it gives up its oxygen to organic matter, it is a powerful decolorizing or bleaching agent. Dilute solutions give a red color to litmus paper, bleaching the latter on drying. "When chromic acid is heated, its color darkens, and finally becomes black, but is restored on cooling. At 192° to 193° C. (377.6° to 379.4° F.) it fuses to a reddish-brown liquid, which, on cooling, forms a dark-red, brittle mass (often enclosing cavities filled with crystals), furnishing a scarlet powder. Above 250° C. (482° F.) it begins to decompose into green chromic oxide and free oxygen, and, after protracted heating, leaves a residue of pure chromic oxide, which should yield nothing soluble to water. A solution of 1 Gm. of chromic acid in 100 Cc. of water previously acidulated with a few cubic centimeters of hydrochloric acid should not be rendered turbid on the addition of 1 Cc. of barium chloride T.S. (absence of sulphuric acid)"—(*U. S. P.*).

Action and Medical Uses.—Chromic acid is exceedingly destructive to all lower forms of life. Small animals, such as mice, are entirely dissolved by it at a somewhat elevated temperature, not excepting even the bones, teeth, and hair. It coagulates albumen even more readily than nitric or carbolic acids or corrosive sublimate. Locally applied to the skin it is an exceedingly active corrosive, producing a deep eschar, which falls off in about 2 days, leaving a granulating base, which heals readily. By its contamination with foreign matter, as sulphuric acid, it is rendered painful in action, but when pure acts almost painlessly. If it be swallowed the same destructive action is observed on the tissues over which it passes, and perforation of the stomach may result. Alkalies, especially sodium bicarbonate and borax, and demulcents should be administered and the stomach pump employed. Stimulate by rectal enemas if necessary.

Chromic acid is recommended as an escharotic in the treatment of *piles*; the acid is to be applied freely over the whole of the diseased surface, and when properly managed it will not spread beyond the prescribed limits. It occasions uneasiness for some hours, and sometimes acute burning pain—a slough passes away, and the tumor shrinks and becomes insensible. As soon as its erosive operation is finished, the acid passes into a state of inert pulverulent sesquioxide. It is less painful than other caustics, and may be used to destroy morbid growths. It may likewise be found advantageous in *cancer, malignant tumors, ulcers, cysts, poisoned wounds, bites of dogs, gangrenous and scrofulous ulcers, hospital gangrene, pharyngeal ulcers of a scrofulous or syphilitic origin, and to retracted and ulcerated gums in mercurialized and scrofulous individuals. Tumors of the larynx* may be skillfully removed with it, as well as *adenoid growths of the nasopharynx*. Diluted it forms a good stimulant to *old ulcerations. Syphilitic ulcerations and growths upon the tongue* are to be treated with the acid (10 grains in 1 ounce of water). It is a prompt hemostatic. *Urethral caruncle* may be removed by it, and

uterine leucorrhœa has been stopped by its skillful intra-uterine application, care being taken that the acid is not used strong enough to induce a cervical stricture. One part of the acid to $4\frac{1}{2}$ parts of water forms a solution for removing *syphilitic morbid growths*, as warts, *condylomata*, *genital vegetations*, *phagedenic ulcers*, *papillomata*, etc.; it may be applied by means of a small glass rod, in all cases being careful not to allow it to act upon the healthy tissues, nor to penetrate too deeply or extensively into the parts upon which its action is directed. It has also been recommended in obstinate *granular conjunctivitis*, but should be used with great care, that it may not prove destructive to the cornea especially. *Granulations* and *polypi of the middle ear* may be removed with chromic acid, though it is inferior to salicylic acid for this purpose. Cauterization with chromic acid has been resorted to after the removal of *cholesteatoma* from the tympanum. Its use as a remedy for *hyperhidrosis of the feet* is not to be commended on account of the disagreeable after-effects that have often attended its employment. An aqueous solution of chromic acid of a pale-yellow color is used to harden and preserve nerve and muscle tissue, so that they may be cut into thin sections for the microscope. Pus, mucus, blood corpuscles, and other delicate structures for microscopic investigation may be preserved in a solution of 1 part of chromic acid to 20 of water. For topical use the pure acid or its aqueous solution only should be employed. It should be remembered that with glycerin and some other solvents it violently explodes.

ACIDUM CHRYSOPHANICUM.—CHRYSOPHANIC ACID.

FORMULA: $C_{12}H_{10}O_4$. MOLECULAR WEIGHT: 253.39.

Source and History.—Chrysophanic acid was discovered by Schrader, in 1819, in the *Parmelia parietina*, Linné, a common wall lichen. He obtained it impure, and named it "resinous yellow of wall lichens." It was found in this lichen in 1843, and purified by Rochleder and Heldt, who gave it the name *chrysophanic acid*, from its yellow color (*Ann. der Chem. und Pharm.* xlviii). Shortly after this, Schlossberger and Dopping decided the coloring matter obtained from rhubarb to be identical. This coloring matter had been known under the names of rheine, rheumine, rhabarberic acid, rhubarb yellow, etc., names doubtless given to impure forms of chrysophanic acid, *emodin*, especially, being intimately associated with it. Each of these substances are dissolved by benzin, the chrysophanic acid more freely. According to E. Bourgoin, chrysophanic acid is present, in small amount, in senna leaves, and may be obtained by extracting crude cathartin, with ether. It is likewise found in yellow-dock root, in small amount, and a prolific source of it is *araroba* (Attfield).

Preparation.—Chrysophanic acid may be prepared from *araroba*, as follows: Mix in a flask 1 part of *araroba*, in powder, with 8 parts of benzin, and bring to a boil; filter while hot, and when the liquid ceases to pass, return the undissolved matter to the flask, and add 8 parts of benzin; boil, and filter, as before. Mix the filtrates, and evaporate to dryness. Dissolve the yellowish powder in 16 parts of boiling alcohol, filter, and add to the filtrate 32 parts of cold distilled water. Allow this to stand for 24 hours, then separate the yellow precipitate, by means of a muslin strainer, or filtering paper, and dry by exposure to the atmosphere.

From RHUBARB, chrysophanic acid may be obtained by exhausting the coarsely-ground root with water, evaporating the solution to dryness, extracting the residuum with boiling benzin, then evaporating the benzin, and, finally, purifying the residue by solution in hot alcohol, and precipitation with water, the same as stated above, in procuring it from *araroba*. Thus obtained, it contains *emodin*, but is pure enough for all practical purposes. The yield from rhubarb is small.

Description.—When pure, chrysophanic acid is in golden-yellow needles, but considerable of that at present upon the market is in the form of a brownish-yellow powder. Subsequent investigations showed it to be dioxymethyl anthraquinone ($C_{12}H_{10}O_4$), while *emodin* was ascertained to be trioxymethyl anthraquinone ($C_{12}H_{10}O_5$).

Chrysophanic acid is volatile at high temperatures, is soluble to a slight extent in cold, and a little more freely in hot water. It dissolves readily in alcohol, ether, benzin, and glacial acetic acid, to which it imparts a yellow color. Cold sulphuric acid dissolves it without decomposition, and with the formation of a red color, from which solution water precipitates it in yellow flakes. It dissolves in alkaline solutions, with the production of a beautiful red color, from which solution excess of acids precipitates it, and the liquid becomes decolorized. It has but little taste and no odor. Its fusing point is at 162° C. (between 323° and 324° F.).

Action, Medical Uses, and Dosage.—Chrysophanic acid has been chiefly employed as a local application in certain cutaneous affections, as *mentagra*, *eczema*, *herpes tonsurans*, *herpes circinati*, *psoriasis*, *acne rosacea*, etc. It is generally applied in the form of an ointment, consisting of from 10 to 120 grains of the acid to 1 ounce of hot lard (360° F.), with which the acid must be thoroughly incorporated. The parts affected having been carefully washed, to remove fatty substances, and any existing scales (*squamæ*) having been softened and carefully removed, this ointment is to be well rubbed in upon the parts, 2 or 3 times a day. The strength of the ointment, and the number of applications per day, will depend considerably upon the amount of irritation occasioned, as it frequently gives rise to more or less irritation, or even inflammation of the skin. When applied about the face and head, care should be taken to protect the eyes from its irritant action. Its use is often objected to by patients, on account not only of its staining the clothing and bed-clothes a dull purple color, but likewise of its giving a more or less dark purplish tint to the skin, and a yellow color to the hair, with which it comes in contact. Mr. Balmano Squire, of London, Eng., to whom we are indebted for a knowledge of this agent, states that a careful use of bleaching powder will remove the stains from clothing; and liquor potassæ, considerably diluted with water, will, it has been stated, discharge the discoloration of the skin and hair. While rubbing it upon the parts, the fingers may be protected from discoloration by wearing india-rubber finger tips, or by rubbing the stained parts with benzol.

Internally, but little is satisfactorily known as to the effects of chrysophanic acid. In small doses, from 4 to 8 grains, it has occasioned vomiting and in doses of from 10 to 20 grains both vomiting and purging. The time of action varies from 4 to 24 hours after it has been taken, and persists, in many cases, for 2 or 3 days. Liquor potassæ, taken subsequently to the dose of the acid, appears to increase its activity. Napier states that *psoriasis* yielded to half-grain pills of chrysophanic acid administered 3 times a day, after meals, continuing the drug until its physiological effect, gastro-intestinal irritation, was felt. Arsenic and various local applications had been used without producing any good results. In one case as much as 9 grains in 24 hours were taken without deleterious effects.

ACIDUM CITRICUM (U. S. P.)—CITRIC ACID.

FORMULA: $\text{H}_3\text{C}_6\text{H}_5\text{O}_7 + \text{H}_2\text{O} = \text{C}_6\text{H}_7(\text{OH})(\text{COOH})_3 \cdot \text{H}_2\text{O}$. MOLECULAR WEIGHT: 209.50.

SYNONYMS: *Acidum citri*, *Acidum limonum*, *Acidum limonorum*, *Acidum limonis*.

"An organic acid, usually prepared from lemon juice"—(U. S. P.).

Source and History.—Citric acid of commerce is prepared from the juices of the lemon, the lime, and the bergamot. It was first obtained, in 1776, by Retzius, who distinguished it from acetic and tartaric acids. In 1784, Scheele first obtained it in crystalline form. In 1880, it was prepared from glycerin, and also from malic acid. Besides being derived from the sources named, it exists in a free or combined state as citrate of calcium or potassium in many fruit-juices, as of whortleberries, cranberries, gooseberries, strawberries, blackberries, raspberries, red elderberries, currants, cherries, tomatoes, tamarinds, cayenne, and in the fruits of bittersweet and of a solanaceous plant of South America and Mexico, known as the "*tomato de la paz*" (*Cyphomandra botacea*). It is also present in Jerusalem artichoke, dahlia tubers, and in the rhizomes of red puccoon, and *Asarum*

europæum. Both the tobacco plant and lettuce contain it. While abundant in the red elderberry the present supply is almost entirely derived from fruits of the orange family. England produces the acid on a large scale from Italian lemons and limes. It is also made from the sour oranges of Florida.

Preparation.—The juice, if fresh and from sound fruit, is first clarified by boiling, then strained and saturated to excess with calcium carbonate or milk of lime. If the juice be derived from decayed fruit, vinous fermentation is allowed to proceed instead of boiling it. The calcium citrate is then precipitated in hot water (being less soluble in hot than in cold water) and the supernatant liquid drawn off. The calcium salt is then washed with hot water to purify it. A slight excess of diluted sulphuric acid is now added to decompose the calcium citrate. By this process calcium sulphate is thrown out after which the citric acid solution is drawn off. The calcium sulphate is then agitated with either very cold or hot water, and the washings, together with the citric acid solution, are then heated by steam until of the consistence of syrup when it is crystallized in leaden vats. Crystallization is facilitated by the presence of sulphuric acid; by redissolving the acid in a little water and purifying with animal charcoal, the commercial crystals will be deposited from the filtered solution.

Description and Tests.—Citric acid is that acid whose sourness is typical of that of the lemon. It occurs in "colorless, translucent, right-rhombic prisms, odorless, having an agreeable, purely acid taste; efflorescent in warm air, and deliquescent when exposed to moist air. Soluble at 15° C. (59° F.), in 0.68 part of water, and in 1.61 parts of alcohol; in about 0.4 part of boiling water, and in 1.43 parts of boiling alcohol; also soluble in 18 parts of ether. When heated to about 75° C. (167° F.) the acid begins to lose its water of crystallization; at about 135° C. (275° F.) it becomes anhydrous, and melts between 135° and 152° C. (275° and 305.6° F.). When slowly ignited it is gradually decomposed without emitting the odor of burning sugar (difference from tartaric acid), and is finally consumed without leaving more than 0.05 per cent of residue"—(U. S. P.). It reddens litmus and forms the line of salts known as citrates, of which the alkaline salts are freely soluble in water. Calcium citrate is soluble in cold, but not in hot water. The dehydrated acid when heated to 155° C. (311° F.) yields water and *aconitic acid* identical with that obtained from aconite, achillea, hellebore, and other plants.

The aqueous solution of citric acid spoils by keeping, forming acetic acid as one of its products. A solution of about the strength of lemon juice may be prepared by adding to one ounce of water about two-thirds of a drachm of citric acid. A portion of this added to water until sufficiently sour and then sweetened to taste, affords a fairly good substitute for lemonade. The addition of a small portion of lemon essence improves the taste. A solution of 1 part of the acid to 2 parts of distilled water will keep sufficiently long to be utilized at the "soda counter." Heated with caustic potash or with nitric acid, citric acid is converted into oxalic acid.

"On adding 1 Cc. of an aqueous solution (1 in 10) of the acid to 50 Cc. of calcium hydrate T.S. (or so much more of the latter that the mixture has an alkaline reaction), the liquid remains clear. Upon boiling this for about one minute, it becomes opaque through the precipitation of calcium citrate, which redissolves on cooling. If 1 Gm. of the powdered acid be dissolved in 5 Cc. of a cold solution (1 in 3) of potassium acetate, the liquid should remain clear, even after the addition of an equal volume of alcohol (absence of tartaric or oxalic acid). On mixing 10 Cc. of a 10 per cent aqueous solution of the acid with a quantity of ammonia water insufficient to neutralize it completely, and adding to one-half of this liquid 1 Cc. of ammonium oxalate T.S., it should remain clear (absence of calcium). The other half, mixed with a few Cc. of hydrogen sulphide T.S., should not deposit a colored precipitate, nor acquire more than a faintly brownish-yellow tint (limit of metallic impurities). On treating 10 Cc. of a 1 per cent aqueous solution of the acid with 1 Cc. of barium chloride T.S. and a few drops of hydrochloric acid, the liquid should not show any turbidity within five minutes (limit of sulphuric acid). To neutralize 3.5 Gm. of citric acid should require 50 Cc. of potassium hydrate V.S. (each Cc. corresponding to 2 per cent of the pure acid), phenolphthalein being used as indicator"—(U. S. P.).

Action, Medical Uses, and Dosage.—Though fatal to rabbits, cats, and other animals, producing heart failure, violent tetanic convulsions, and finally death, it has not produced the death of man. Its continued use acts destructively on the teeth. Large doses are irritant to the gastro-intestinal tract, and may act as a poison in this way. It is principally carried off by the kidneys, rendering the urine acid if the amount taken be large. The coagulability of the blood is retarded by it. This acid is used as a refrigerant and antiscorbutic, rendering the blood more fluid by lessening its coagulability. In all *febrile diseases*, a sweetened solution of it will be found a very beneficial drink, especially in those cases where the tongue is coated brown, dark or red; it may be flavored with a few drops of the essence of lemon. It is likewise beneficial in *scurvy* (though far less effective than fresh lemon juice), *acidity of the stomach* and some peculiar forms of *sick headache*. It has also been advised in *gout* and *inflammatory rheumatism*, but its liability to occasion gastric acidity, and increase of uric acid in the urine, are serious objections to its employment in these diseases, aside from the failures that have followed its use on many occasions. Prof. Scudder recommends lemonade or lemon juice in those cases only where the tongue is red and long, and the inflamed parts show excessive redness. A lemonade powder, which will keep for years if preserved dry, is made by mixing together 4 ounces of powdered white sugar with 3 drachms of powdered citric acid and 2 drops of oil of lemon. Half a teaspoonful of this mixture may be dissolved in a tumbler of water for a beverage. The continued use of citric acid disturbs the functions of the digestive organs. M. Girard, Chief of the Paris Municipal Laboratory, claims that citric acid is an efficient purifier of polluted water, 1 grain of the acid being destructive to the micro-organisms in a quart of water. For this reason he advises the use of lemonade during *epidemics*. Locally, it is useful in *hypertrophied tonsils*, *elongated uvula*, and *genital pruritis*. The dose of citric acid is from 5 to 30 grains; lemonade at will.

Specific Indications.—Inflammatory rheumatism, showing excessive redness of inflamed parts and elongated, reddened tongue; scorbutus; febrile states, with red, elongated tongue. Lemon juice as an antirheumatic when the tongue is markedly red, papillæ prominent, and usually thinly-coated white.

Related Product.—ACIDUM CITRICUM SACCHARATUM (N. F.), *Saccharated citric acid*. *Formulary number, 5*: "Citric acid (U. S. P.), in very fine powder, six hundred and twenty-five grammes (625 Gm.) [1 lb. av., 6 ozs., 20 grs.]; sugar, in very fine powder, three hundred and seventy-five grammes (375 Gm.) [13 ozs. av., 100 grs.]. Triturate the powders together until intimately mixed, and preserve the product in well-stoppered bottles. *Note.*—This saccharate, when dissolved in water with an equal weight of saccharated sodium carbonate (F. 341), will form a neutral solution, and it is introduced into this formulary for the convenient preparation of effervescent powders (F. 319). This saccharate contains 62.5 per cent of crystallized citric acid"—(*Nat. Form.*).

ACIDUM FORMICUM.—FORMIC ACID.

FORMULA: $\text{H}_2\text{CO}_3 = \text{HCHO}_2$. **MOLECULAR WEIGHT:** 45.89.

Source and History.—This acid was first obtained by the distillation of ants, by Samuel Fisher (Lavoisier). A. S. Marggraff examined it in 1749, and Ardwissan and Oehrn, of Leipsic, in 1777, fairly establishing its identity as a definite compound. However, in 1802, Fourcroy and Vanquelin endeavored to prove that it was a mixture of acetic and malic acids; but their opinions were refuted by Suersen and Gehlen. Berzelius (1817) first attempted to determine its composition (*Annals of Philosophy*, Vol. IX, p. 107), by burning formate of lead and chlorate of potassium in a glass tube, thus deciding that it contained oxygen, hydrogen, and carbon. Formic acid is found in certain caterpillars, and, doubtless, the "*bombic acid*" Lavoisier mentions as being obtained from silk-worm larvæ that are changing to chrysalides, was impure formic acid.

The "*spirit of magnanimity*," of Hoffman, was made by extracting red ants with spirits of wine. Later, Mr. F. Will has shown that the fluid in the hairs of a species of caterpillar, which causes inflammation of the skin when handled, and the poisoning by the stings of some insects, is due to the formic acid present. It has also been demonstrated that the stinging hairs of the nettle,

Urtica urens and *Urtica dioica*, contain this acid. Formic acid is also found in pine-tree leaves, and in the blood, bile, urine, perspiration, and muscular tissues of man.

Preparation.—Formic acid derived its name from the fact that it was obtained by distillation of red ants (*Formica rufa*, Linné). Doebereiner discovered, in the early part of the present century, that it could be prepared artificially by the distillation of tartaric acid, water, sulphuric acid, and black oxide of manganese. At present, it is known that many organic bodies yield this acid, when distilled with black oxide of manganese and sulphuric acid, or with chlorinated lime, or with bichromate of potassium; but decidedly the best process is that based upon the principle discovered by Berthelot (*Comptes Rendus*, March 1856), that oxalic acid and glycerin will produce it, when heated together. 4 parts each of oxalic acid and glycerin are to be mixed with 1 part of water, and a heat of 100° C. (212° F.) applied 12 or 15 hours, or until the acid is decomposed. The residuum is now to be mixed in a still with its bulk of water, and distilled. It is then again mixed with the same quantity of water, and distilled, the operation being repeated, if the formic acid remains in amount to justify. In this process monoformate of glycerin is formed as an intermediary product, which, upon distillation with water, splits into glycerin and formic acid, as follows:

The distillates are to be mixed, neutralized with carbonate of lead, then evaporated to dryness, and distilled with sulphuric acid if desired pure; generally, however, the diluted acid is preferable. Another process was suggested by the Professors Rogers, in 1847, in which sugar was added to a solution of bichromate of potassium, and distilled, while sulphuric acid was slowly added. This requires great care, however, as, according to our experience, if the acid is allowed to enter too rapidly, the reaction becomes very violent, and may occasion disastrous effects. Besides, if distillation is conducted beyond a certain point, sulphurous acid contaminates the distillate.

Description.—Formic acid is represented by the formula HCHO_2 , thus a molecule contains the elements of water, H_2O , and carbonic oxide, CO . It is a colorless, strongly acid liquid, when concentrated capable of removing the cuticle. It does not char when heated, even with sulphuric acid, but in the latter case splits up into water and carbonic oxide. It dissolves freely in water, glycerin and alcohol, and forms salts soluble in water. When ignited, the vapor burns with a blue flame. Its odor is pungently acid, and its taste a sharp, biting sour. The salts of gold, platinum, mercury and silver are reduced when heated with formic acid, and the metals deposited. Anhydrous formic acid crystallizes below 0° C. (32° F.), and, according to Attfield, boils at 105° C. (221° F.). The experiments of Jardin show that the molecule of formic acid is incapable of furnishing carbon assimilable to even the simplest cellular organisms, and solutions of formiates remain perfectly clear many months.

Action, Medical Uses, and Dosage.—Formic acid applied to the skin acts as an irritant, and produces a violent, burning pain, and may vesicate. If kept in contact with the tissues, it will even cause ulceration. Gastro-intestinal inflammation and bloody urine were the results of its administration to rabbits. In man it acts as an excitant to the circulation, and increases the renal secretions, sometimes causing the passage of clouded, offensive urine. Moderate doses induce hurried respiration and rise of temperature, while larger doses cause rapid breathing, and lower the temperature. If administered at all, it should be largely diluted.

Formic acid is rarely employed in medicine; it was, at one time, used externally as a local irritant, in *sluggish capillary circulation*, in certain *painful affections*, and in *enfeebled or paralytic conditions of the limbs*. The German *Pharmacopœia* has a "spirit of ants" [*Spiritus Formicarum* = Formic acid (2), water (26), alcohol (70)], used in *chronic rheumatism*, etc., in doses of from 10 drops to a fluid drachm; also as an external rubefacient. It may also be made by macerating, for 2 days, 1 part of fresh red ants in 1½ parts, each, of alcohol and water, and then distilling off 2 parts. It forms a clear, acid fluid, yielding feathery crystals when mixed

with $\frac{1}{16}$ part of subacetate of lead solution. Combined with ammonium (*formiate of ammonium*), the salt formed has been tried in *chronic paralytic affections*, and even in *epilepsy*, but without success; the dose is 4, 5, or 6 grains.

ACIDUM GALLICUM (U. S. P.)—GALLIC ACID.

FORMULA: $\text{HC}_7\text{H}_5\text{O}_6 + \text{H}_2\text{O}$. MOLECULAR WEIGHT: 187.55.

SYNONYMS: *Trioxibenzoic acid*, *Dioxysalicylic acid*.

"An organic acid, usually prepared from tannic acid"—(U. S. P.).

Source, History, and Formation.—Though existing in a number of astringent plants, the greater portion of commercial gallic acid is derived from nutgalls. Scheele (1785), who first obtained it pure, established its non-identity with tannic acid. The manner of formation of gallic acid from nutgalls has been a subject of much discussion and experimentation. Before investigations were begun it was believed to exist ready-formed in galls, but in 1833 Pelouze showed that the larger portion of it was derived from the tannin of the galls, and advanced the theory that this conversion was accomplished by oxidization by the atmospheric oxygen, by which carbon dioxide was driven off. The elder Robiquet (1837) showed that its conversion could be accomplished without the aid of oxygen and without evolving carbon dioxide, but that it resulted from a ferment called *pectase*. Wetherill (1847), and subsequently Mulder (1848), attempted to show that tannic acid differed from gallic acid only in the possession of a larger amount of water of crystallization. Liebig believed the change to be due to the liberation of a carbohydrate. In 1854 Strecker came to the conclusion that tannin was a glucosid, for by boiling it with diluted mineral acid he obtained a large amount of gallic acid and considerable glucose. This view was generally accepted for a long time, though opposed by the younger Robiquet (1854) and Hlasiwetz (1867), who advanced different theories regarding the supposed glucosid. The present theory is that advanced by Schiff (1871) and supported by others, that pure tannic acid be viewed as *digallic acid* (this being the first anhydrid of gallic acid), and that natural tannin is the glucosid of *pure tannic*, or *digallic acid*, for by the action of hot diluted mineral acids or a nitrogenous ferment upon it, digallic acid and glucose are evolved.

Preparation.—Considerable gallic acid is now made by the sulphuric acid process. The *British Pharmacopœia* directs that 1 part of coarsely powdered galls be boiled for one-half hour with 4 parts (fluid measure) of diluted sulphuric acid and strained through cloth while hot. Crystals are deposited when cool, and are to be collected, treated with animal charcoal, and repeatedly crystallized.

The method more generally employed is as follows: Take of finely-powdered nutgalls, 3 Troy pounds. Mix the galls with enough distilled water to form a thin paste and expose the mixture to the atmosphere by allowing the vessel to stand in a warm place for about 4 weeks, taking the precaution to see that it has at all times sufficient distilled water to maintain a thin, pasty consistence, and to stir the mass occasionally with a glass rod. A porcelain or glass vessel should be used for this operation, and in no instance should an iron dish be employed, as iron or the presence of iron salts give to the product a color very difficult of removal. After exposure of the mixture for the required length of time the pasty mass is to be expressed and the residue is added to 8 pints of distilled water and boiled for a short time, and filtered through pure animal charcoal while hot. Upon cooling crystals of gallic acid are deposited, which, if further purification is necessary may be again dissolved, treated with charcoal, and recrystallized.

Description.—Gallic acid forms delicate "white, or pale fawn-colored, silky, interlaced needles, or triclinic prisms, odorless, having an astringent or slightly acidulous taste; permanent in the air. Soluble at 15° C. (59° F.), in 100 parts of water, and in 5 parts of alcohol; in 3 parts of boiling water, and in 1 part of boiling alcohol. Also soluble in 40 parts of ether, and in 12 parts of glycerin. Very slightly soluble in chloroform, benzol, or benzin. When heated at 100° C. (212° F.), the acid loses its water of crystallization (nearly 9.6 per cent.). At about 222° C. (431.6° F.), it begins to melt, and at a higher temperature it is grad-

ually decomposed. At a low, red heat it is consumed without leaving a residue. Gallic acid has an acid reaction"—(U. S. P.).

Gallic acid is entirely sublimed when heated, yielding carbonic acid gas and *pyrogallol* ($C_6H_3O_3$).

Tests.—"If 5 Cc. of a cold, saturated, aqueous solution of the acid be treated in a watch-glass, with 6 drops of sodium hydrate T.S., the liquid will gradually acquire a deep-green color, which is changed to reddish or brownish-red by acids. Gallic acid neither colors nor precipitates pure ferrous salts, but forms a bluish-black precipitate with ferric salts. On adding to a cold, saturated, aqueous solution of gallic acid some calcium hydrate T.S., a bluish-white precipitate will form, where the test solution is temporarily in excess, and will disappear on shaking. When the test solution has been added in excess, the precipitate no longer dissolves, and the liquid acquires a tint which is blue by reflected and green by transmitted light, and becomes pink on the addition of a large excess of calcium hydrate T.S. (distinction from tannic acid). An aqueous solution of the acid should not precipitate alkaloids, gelatin, albumen, or starch T.S. (difference from and absence of tannic acid)"—(U. S. P.).

Solutions of gold, platinum, and silver salts, as well as those of the allied metals, are reduced by gallic acid or its salts, the solution of argentic nitrate converting gallic into tannic acid.

Action, Medical Uses, and Dosage.—Gallic acid does not coagulate albumen, and when ingested is quickly absorbed, and rapidly discharged by the kidneys, over the secretions of which, as well as of the skin, it has a marked control. Gallic acid is much inferior to tannic acid as a topical astringent, but administered internally, it is more powerful as a remote astringent. Indeed, tannic acid, in its passage through the system, becomes changed into gallic acid. As a remote astringent, gallic acid has been found very beneficial in *uterine, pulmonary, and nephritic hemorrhages*, and all *hemorrhages* of a passive character. *Menorrhagia* has promptly ceased under its use. Give 5 grains, in pill form, 3 or 4 times a day during the flow, as well as during the intermenstrual period. It is best adapted to chronic passive cases. It has also been found useful in *night sweats, pyrosis, chronic mucous discharges* from the bowels and bladder, and has some reputation in arresting the excretion of albumen in *Bright's disease* of the kidney, and assists in maintaining the patient's strength. In *hemoptysis* give 3 grains each of gallic acid and Dover's powder every 2 hours, and at the same time administer ergot by the mouth or hypodermatically (Locke). From 2 to 5 grains every 3 hours controls bleeding from the nose and bowels during *typhoid fever*. As a remedy in *diabetes insipidus* it is asserted to arrest the polyuria by promptly constringing the relaxed renal capillaries. From 10 to 30 minims of the glycerole should be administered 4 times a day (Webster). Some cases of old, *purulent conjunctivitis* are cured by it, and it is of value in *trachoma* with soft, pasty granulations. One part of gallic to 3 parts of tannic acid should be insufflated upon the parts twice daily (Foltz). It has given benefit in *purpura*. Costiveness is not produced by its use. Its dose is from 3 to 20 grains 3 times a day, or oftener; it may be used in the same form as the tannic acid; of the glycerole, 5 to 60 minims. Its hydro-glycerin solution may be employed as a wash, gargle, or injection.

Specific Indications and Uses.—Passive hemorrhages, with pulse feeble and extremities cold, skin inelastic, and capillaries relaxed; hematuria, with nausea, vertigo, headache, and dull aching in the region of the kidney; soft, pasty, granular conjunctivitis.

ACIDUM HYDRIODICUM.—HYDRIODIC ACID.

FORMULA: HI. **MOLECULAR WEIGHT:** 127.53.

SYNONYM: *Hydrogen iodide, Iodide of hydrogen, Acidum iodhydricum.*

Source and History.—This substance was discovered shortly after the detection of iodine. The process for its preparation, recommended in Dana's *Chemical Philosophy* (1825), by mixing moistened iodine with phosphorus, is almost identical with that offered in some of the more recent works. A solution of the gas was official in the U. S. P. (1860), being made from iodine, by decom-

posing hydrogen sulphide with iodine in the presence of water, thus: $2\text{H}_2\text{S} + \text{I}_2 = 4\text{HI} + \text{S}_2$. This formula, according to Naumann (*Roscoe's Treatise on Chemistry*, Vol. I, p. 160), can not yield an acid of greater specific gravity than 1.56.

Preparation.—It may be prepared in practice by mixing 30 grains of powdered iodine with 5 fluid ounces of distilled water, and then passing hydrogen sulphide through the mixture, until the iodine has disappeared; saturate this liquid with iodine, and again decolorize, with hydrogen sulphide. Repeat the operation until 480 grains of iodine have been used. The liquid now contains much precipitated sulphur and some free hydrogen sulphide. Boil it gently, to drive off the latter impurity, then filter, and bring the filtrate to the measure of 6 fluid ounces, by washing the filter with distilled water. If an attempt is made to pass the hydrogen sulphide through water mixed with all of the iodine, the first action will be attended by a deposition of sulphur over the particles of iodine, thus protecting the enveloped particles from the action of the gas. This objection is overcome by taking advantage of the fact that iodine is soluble in a solution of hydriodic acid, and thus we successively dissolve the iodine, and then pass hydrogen sulphide through each solution.

Description.—Hydriodic acid is a colorless, non-inflammable gas, possessing strong acid properties, and a suffocating odor. It fumes when exposed to the atmosphere, and has the sp. gr. (air=1) of 4.3737. Gay-Lussac demonstrated it to be composed of equal volumes of vapor of iodine and of hydrogen, by allowing it to remain in contact with mercury, whereby all of the iodine was absorbed, and the original volume reduced one-half. It is decomposed by heat, the iodine exhibiting itself as a violet vapor. Oxygen, chlorine, and bromine decompose it, liberating iodine. Sunlight slowly decomposes the gas, but does not affect its solutions if they be kept free from air. Faraday discovered that at 0°C . (32°F .), under the pressure of 4 atmospheres, it condenses into a colorless liquid. At -55°C . (-67°F .) it freezes to a clear, colorless, transparent mass, resembling ice. It forms salts with the vegetable alkaloids.

Solution of hydriodic acid is the hydriodic acid of commerce. It somewhat resembles hydrochloric acid, but is less stable. It can not be kept for any length of time, as, by exposure to the air, oxygen unites with the hydrogen, forming water, and the iodine is liberated, which, dissolving in the solution, imparts to it a brownish-red color. This change may be corrected to some extent by the addition of a small quantity of sodium hyposulphite, about $\frac{1}{2}$ grain to the ounce of acid (Dunn, 1868). As soon as made, it should be securely sealed in small, glass-stoppered bottles, filled to the stopper, and placed in a cool situation until used. It has a pungently sour, styptic taste.

Action, Medical Uses, and Dosage.—Dr. Andrew Buchanan, of Glasgow, Scotland, introduced this acid as a medicine. He believed it to possess all the therapeutic virtues of iodine, without its irritant qualities. His views have, in a large measure, been substantiated by other physicians, and it is now given whenever the introduction of iodine into the system is required. Used in the form of a syrup containing 1 per cent of absolute acid, it is found to be very efficient in all forms of *scrofulous diseases*, and is much employed by members of the regular school of medicine in *chronic catarrhal pneumonia*, and other *chronic pulmonary complaints*. It has served a good purpose in the spasmodic form of *asthma* in gouty subjects. *Pulmonary indurations*, following pneumonia, are reduced by it, and absorption of *pleuritic deposits* favored by the administration of the syrup. In this way a peculiarly effective action is obtained from the nascent iodine, which is liberated in the system. In many cases its use should be preferred to that of the element itself. Should free iodine be liberated in the syrup, which may be known by its coloring the preparation yellowish or red, it may be overcome by the addition of a small amount of sodium hyposulphite, and if this be not at hand, the medicament may be administered in rice-water, or starch-water. By the latter method, by the action of these amylaceous substances, the free iodine will be converted into an inert iodized starch. Syrup of hydriodic acid is recommended in *periodic hyperæsthetic rhinitis*, or *hay asthma*, and undoubtedly has some beneficial effect in this unpleasant malady. The acid may also be used by dropping 1 or 2 drops on a lump of sugar and administering every 2 or 3 hours (Prof. Howe, in *Ec. Med. Jour.*, 1884). It has been used

According to A. Bertrand (*Compt. Rend.*, lxxxii, p. 96), phosphoric acid may be substituted for sulphuric, when distilling with an alkaline bromide, thus overcoming the liability of the product to contain sulphurous acid. The composition of hydrobromic acid is represented by the formula HBr ; the reaction which takes place when made from phosphorus, bromine, and water, being represented by the formula $\text{P} + 3\text{Br} + 3\text{H}_2\text{O} = 3\text{HBr} + \text{H}_3\text{PO}_3$; that when made from sulphuric acid and bromide of potassium, by the formula, $2\text{KBr} + \text{H}_2\text{SO}_4 = 2\text{HBr} + \text{K}_2\text{SO}_4$.

Description and Tests.—Hydrobromic acid is a colorless gas, fuming in the air, and irritating to the lungs when inhaled. It condenses to a colorless liquid, at a temperature of -71.6°C . (-99°F .), and solidifies, to an ice-like mass, at -87.2°C . (-125°F .) (*Faraday, Phil. Trans.*, 1845). Its diffusive power is that of hydrochloric and hydriodic acids (Graham). Aqueous hydrobromic acid is colorless, and imparts an acid taste. If very weak it becomes stronger, or if very strong weaker, by distillation, until the acid within the retort contains from 47 to 48 per cent of hydrobromic acid. Hydrobromic acid evaporates completely, no residuum remaining; should sulphuric acid be present, a white precipitate will be formed, upon the addition of solution of chloride of barium. Should hydriodic acid be present its detection is rendered easy by exposing a quantity of the acid to the air. If it turns reddish or yellow, and gives a blue precipitate with starch-paste, iodine is present as a contamination. It is *incompatible* with alkalies and alkaline carbonates, with which it forms "bromides;" likewise, with plumbic, argentic, and mercurous salts, in solution, with which it forms precipitates of the corresponding bromides.

ACIDUM HYDROBROMICUM DILUTUM (U. S. P.). *Diluted hydrobromic acid.*—The official acid contains 10 per cent of absolute acid, and is described in the Pharmacopœia as—"A clear, colorless liquid, odorless, and having a strongly acid taste. Specific gravity about 1.077 at 15°C . (59°F .). Miscible, in all proportions, with water and alcohol. By heat it is completely volatilized. On distilling it water and weak acid first pass over. When the temperature of 126°C . (258.8°F .) is reached, an acid of 47.8 per cent remains, which may be distilled unchanged. With litmus paper it shows a strongly acid reaction. On adding an equal volume of chlorine water to diluted hydrobromic acid, bromine is liberated, and if a few drops of chloroform are now added and shaken with it, the bromine will dissolve in the chloroform with a yellow color (absence of iodine). Silver nitrate T.S. causes a yellowish-white precipitate, somewhat soluble in hydrobromic acid, insoluble in diluted nitric acid, very slightly soluble in ammonia water, but more soluble in stronger ammonia water. Copper sulphate T.S. produces a deep-red color upon addition of sulphuric acid. On being kept for some time the acid should not become colored. Barium chloride T.S. should not produce a turbidity or precipitate (absence of sulphuric acid). If 1 Cc. of the acid be mixed with 1 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), and a small piece of pure tin-foil added, no brown coloration should appear within half an hour (limit of arsenic). To neutralize 8.08 Gm. of diluted hydrobromic acid should require 10 Cc. of normal potassium hydrate V.S. (each cubic centimeter corresponding to 1 per cent of the absolute acid), phenolphthalein being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Hydrobromic acid can not be administered internally, unless considerably diluted, on account of its powerfully corrosive qualities. Drs. D. C. Wade and J. M. Fothergill have found it efficacious in the *headache* that frequently follows the administration of quinine, as well as of ferruginous preparations. If given after the doses of the latter agents it prevents the sensations of fullness and pain that are apt to be occasioned by them, especially with those laboring under cerebral anemia. This acid has also been found useful in all forms of *nervous excitability*, sometimes acting more efficaciously when in combination with quinine, which it readily dissolves. In *nervous exhaustion* from excessive use of tea, or alcoholic drinks, in *hysteria* from ovarian derangement, *nymphomania*, in *sleeplessness* from celibacy, in *gastric irritability*, in *menorrhagia*, and in the *vomiting of pregnancy* it has been administered with success. In association with quinine and digitalis it has been found of service in *enfeebled and excited conditions of the heart*; with spirit of chloroform and syrup of squill, it forms a pleasant and efficacious mixture in all *coughs*. It is a service-

able remedy in *nervous headache*, and according to De Schweinitz is useful in that form of *headache* resulting from *eye-strain*. Hale recommends it in *febrile disorders* with marked irritability and restlessness, the tongue being red and dry. When considerable *cerebral excitement* exists from physical or mental overwork, or during febrile affections its internal administration will prove highly serviceable. Dr. E. Woakes and others have derived great benefit from its use in cases of *tinnitus aurium*, resulting from the use of quinine, and from congestion of the parts, especially in those instances in which the tinnitus was of a pulsating, or knocking, character; doses of 15 minims of the acid in water were repeated every 4 hours. This acid appears to possess the therapeutical virtues common to the bromides of potassium and of sodium, although less persistent in its action; and unlike them, it possesses the advantage of not occasioning the troublesome acneiform eruption so often following their administration. *Epilepsy*, so frequently improved under the use of the alkaline bromides, is rendered worse by the administration of hydrobromic acid. Hydrobromate of quinine has been found a much better form, in solution, than the sulphate, for subcutaneous injection. Dose of diluted hydrobromic acid (U. S. P.) containing 10 per cent absolute acid, 10 drops to fʒiij, in sweetened water if preferred; quinine hydrobromate grains 1 to 20.

Specific Indications and Uses.—Dry red tongue, headache from cerebral hyperemia, delirium, pyrexia, tinnitus aurium, and especially when resulting from cinchonism; dull pain in the abdomen, with fretfulness and peevishness.

ACIDUM HYDROCHLORICUM (U. S. P.)—HYDROCHLORIC ACID.

FORMULA: HCl. MOLECULAR WEIGHT: 36.37.

SYNONYMS: *Hydrogen chloride*, *Muriatic acid*, *Acidum muriaticum*, *Acidum chlorhydricum*, *Acidum hydrochloratum*, *Marine acid*, *Chlorhydric acid*, *Spirit of salt*, *Spirit of sea-salt*.

"A liquid composed of 31.9 per cent, by weight, of absolute hydrochloric acid (HCl=36.37), and 68.1 per cent of water. Hydrochloric acid should be kept in dark, amber-colored, glass-stoppered bottles" (U. S. P.).

Source and History.—Hydrochloric acid was first made, and named the spirit of salt, by the monk, Basil Valentine, and its chemical composition determined by Davy in 1810. It is found in nature, in a free condition, in volcanic gases, and in the gastric juice of mammals. In the form of metal salts, called chlorides, it exists in many minerals, the most conspicuous and useful of which is common salt, hence its large distribution throughout sea-water. Hydrochloric acid is manufactured on an enormous scale in England, as a by-product in the production of sodium carbonate and potash. When the English factories were first established, the importance of this substance was not recognized, and as large quantities of it were generated when common salt was treated with sulphuric acid, it was allowed to pass up the chimneys and go to waste. This escaping gas soon became a nuisance, disturbing all vegetation in the neighborhood for miles around, and legislative interference became necessary. Laws were passed by Parliament to compel the manufacturers to prevent the escape of the gas. The latter found that by bringing the gas into contact with water, it was absorbed, yielding an impure hydrochloric acid, and in this instance the prohibitory law resulted in immense profit to those against whom the ordinance was passed.

Preparation.—Crude hydrochloric acid is produced by the English manufacturers, by allowing the gas which is evolved in the process of converting common salt into sulphates, to be absorbed by water. The gas is passed through coke (packed in a long, upright cylinder) through which water is allowed to trickle, and the gas having great affinity for moisture, is dissolved in it. In order to obtain a purer product, the gas is allowed to pass through a series of stone receivers, the first one being empty to catch and retain any of the sulphuric acid or sodium sulphate that may be carried over. The other receivers are partially filled with water to collect and dissolve the gas after it has passed through the first receiver. To produce the gas, about 115 parts of common salt (sodium-chloride) are saturated with 100 parts (by weight) of strong sulphuric acid. This

mixture is heated in upright, cylindrical iron stills. At first about one-half of the HCl is liberated, and acid sulphate of sodium formed, but on heating to a point considerably above 200° C. (392° F.), the remaining sodium chloride is decomposed by the acid sodium sulphate, thus yielding the full amount of HCl. The residue left in the still is then dissolved in water and crystallized as Glauber's salt, or it may be used directly in making sal soda. A yellow color of variable intensity given the acid produced in this manner, is due to ferric chloride, which is dissolved in it to a slight extent, or it may be caused by organic contamination present in the materials used.

A purer acid for medicinal use, according to the *British Pharmacopæia*, may be prepared as follows: take 48 parts of dried sodium chloride, 44 (80 by weight) parts of sulphuric acid, 36 parts of water, and 50 parts of distilled water. Put the sodium chloride into a glass flask holding at least one gallon, and upon it pour a cooled mixture of the sulphuric acid in 32 ounces of water. A three-necked bottle (provided with a safety tube) containing the remaining 4 ounces of water, is then to be connected to the flask by means of corks and bent glass tubing. Apply heat to the flask, when the disengaged gas will be forced through the tube into the bottle, where it is washed, and by means of another glass tube passed again into a second bottle containing the distilled water.

Description.—I. **HYDROCHLORIC ACID GAS.**—Specific gravity 1.2844. This is an irrespirable, colorless gas, intensely irritating to the broncho-pulmonary surfaces. Owing to its affinity for moisture, it gives rise to clouds of whitish vapor when exposed to the atmosphere. It is neither combustible nor a supporter of combustion. It reddens litmus and is strongly acid. Under a pressure of 40 atmospheres at 10° C. (50° F.), it condenses to *liquid hydrochloric acid*.

II. **CRUDE HYDROCHLORIC ACID.**—An impure, aqueous solution of the gas, of a yellowish to a yellow color, due to the iron present as an impurity. It should not contain arsenic, which is sometimes present as arsenic terchloride, derived from the sulphuric acid employed in making hydrochloric acid. Arsenic, if present, may be separated by adding to 10 parts of the undiluted acid, 1 part of stannous chloride. Metallic arsenic will be thrown down as a brownish precipitate, if the mixture be either heated or allowed to stand for a short time. Filter the liquid and distill. This method is a very delicate test, showing the presence of a millionth part of the arsenic (Bettendorff, *A. J. P.*, 1871, p. 222). Copper and mercury also free it from arsenic, or the diluted acid may be treated with hydrogen sulphide, when arsenic tersulphide will be precipitated.

III. **ACIDUM HYDROCHLORICUM DILUTUM (U. S. P.).** *Diluted hydrochloric acid, Diluted muriatic acid.*—"Hydrochloric acid, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; distilled water, two hundred and nineteen grammes (219 Gm.) [7 ozs. av., 317 grs.]; to make three hundred and nineteen grammes (319 Gm.) [11 ozs. av., 111 grs.]. Mix them. Keep the product in glass-stoppered bottles. Diluted hydrochloric acid contains 10 per cent of absolute hydrochloric acid. Specific gravity about 1.050 at 15° C. (59° F.). It does not fume in the air, and is without odor, but otherwise it corresponds in properties to hydrochloric acid (see *Acidum Hydrochloricum*), and should conform to the same reactions and tests. To neutralize 3.64 Gm. of diluted hydrochloric acid should require 10 Cc. of normal potassium hydrate V.S. (each cubic centimeter corresponding to 1 per cent of the absolute acid), phenolphthalein being used as indicator"—(*U. S. P.*).

IV. **ACIDUM HYDROCHLORICUM (U. S. P.).** *Hydrochloric acid.*—This is an aqueous solution containing 31.9 per cent of absolute hydrochloric acid. It is "a colorless, fuming liquid, of a pungent odor, and an intensely acid taste. Fumes and odor disappear on diluting the acid with 2 volumes of water. Specific gravity about 1.163 at 15° C. (59° F.). Miscible, in all proportions, in water and alcohol. On heating it, at first a stronger acid passes off, until, at 110° C. (230° F.), a liquid containing 20.18 per cent of the absolute acid remains (specific gravity about 1.102 at 15° C.), which distills unchanged, leaving no residue, if the acid was perfectly pure. With litmus paper it shows an intensely acid reaction, even after great dilution. Heated with manganese dioxide, it gives off chlorine"—(*U. S. P.*).

Tests.—With silver nitrate T.S. it yields a white, curdy precipitate, insoluble in nitric acid, but readily soluble in ammonia water, forming a colorless

liquid (absence of copper). If 10 Cc. of the acid be evaporated from a platinum or porcelain capsule, not more than a bare trace of residue should be left (limit of non-volatile impurities). A few drops of chloroform, added to 1 Cc. of hydrochloric acid diluted with 2 Cc. of water, should not become colored, either at once, or after the addition of a few drops of freshly prepared chlorine water, or of a granule of potassium chlorate (absence of iodine or bromine). If 1 Cc. of the acid be diluted with 5 Cc. of water, and 0.5 Cc. of zinc-iodide-starch T.S. added, no blue color should appear (absence of chlorine or bromine). On adding 1 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), together with a small piece of pure tin-foil, to 1 Cc. of the acid, no coloration should occur within one hour (limit of arsenic). If 1 Cc. of the acid be diluted with 5 Cc. of water, and a few drops of barium chloride T.S. added, no precipitate or turbidity should appear within one hour (absence of sulphuric acid), nor should the addition to this mixture of a few drops of decinormal iodine V.S. produce any turbidity (absence of sulphurous acid). When a few Cc. of freshly saturated hydrogen sulphide T.S. are poured carefully on top of an equal volume of hydrochloric acid, no color should develop at the zone of contact (absence of thallium, arsenic, lead, etc.). If 1 Cc. of hydrochloric acid be slightly supersaturated with ammonia water, and 1 Cc. of ammonium sulphide T.S. added, neither a color nor a turbidity should appear (absence of iron, aluminum, etc.). To neutralize 3.64 Gm. of hydrochloric acid, diluted with 10 Cc. of water, should require 31.9 Cc. of normal potassium hydrate V.S. (each cubic centimeter corresponding to 1 per cent of the absolute acid), phenolphthalein being used as indicator"—(U. S. P.). It has been found that if the acid is reddish, selenium is present.

Action, Medical Uses, and Dosage.—Hydrochloric acid, when administered in small doses, creates gastric warmth and quickens the circulation. Decided intoxicating effects may be induced by it, while salivation may result from its continued use. The concentrated acid is violently irritant and corrosive, though it does not attack flesh so energetically as sulphuric acid. A poisonous dose produces intense, burning pain, and the faucial, cesophageal and gastric tissues are discolored. The tongue is swollen and intensely red, with occasional whitish patches. Great restlessness ensues, with a dry, feverish skin, sunken features, dilated pupils, small, irregular, wiry pulse, collapse and death resulting. Vomiting of bloody matter may occur, though more frequently only violent retching takes place. Whitish vapors may be evolved by mouth if the acid be recently swallowed. The acid may be identified if these vapors produce a flocculent, white material when brought in contact with ammonia water. After death the gastric tissues show marked evidence of intense inflammation. It is antidoted by the alkalies, preferably calcined magnesia. If possible, emetics and alkaline carbonates should be avoided, on account of their liability to rupture the already softened stomach by the over-distension occasioned by the copious liberation of carbonic acid gas. Chalk, whiting, soap, and oil are also antidotes to poisonous doses of hydrochloric acid, combating the gastro-enteritis in the usual way. According to Prof. Maisch, hydrogen sulphide is a direct antidote to the poisonous effects of the inhalation of chlorine. Concentrated hydrochloric acid is occasionally used as a topical application to *cancrem oris*, some obstinate *ulcers of the tongue* in certain *syphilitic* and *mercurio-syphilitic diseases*, in *phagedenic ulceration*, and also in *chilblains* or *frost-bites*. As a decalcifying agent it has been used in *caries* of the ossicles of the ear, as well as of the walls of the tympanum and external auditory canal, thus rendering their removal by operation less difficult. Foltz applies it with a broom-straw. Internally it is always diluted, so as to reduce its specific gravity to about 1.038, and which may be effected by adding 1 fluid ounce of the strong acid to 3 fluid ounces of distilled water. The official diluted acid is usually prescribed. The diluted acid has been used as a gargle for *elongated uvula*, *aphthæ*, and the *sore throat of scarlatina*. Internally it has been administered in *typhus* and *typhoid febrile diseases*, *malignant scarlet fever*, some forms of *dyspepsia*, and in *torpor of the liver*; also as a tonic in cases of *phosphatic urine*.

In the use of this agent we are governed by the specific indications, which are a deep-red mucous membrane, with a tendency to decay of the tissues; a

marked depravation of the body fluids, as is evidenced by the raw, slick, beef-like tongue, or the dark-red or dusky, dry and fissured tongue, and the tendency to dark, brownish coloration and deposits, as sordes, upon the lips, teeth and tongue. All the exudations have a dark color. The temperature may be high and yet sedatives fail to act. With these conditions the acid acts kindly, the temperature falls, and the way is paved for the administration of other indicated drugs. These conditions may obtain in low states of any of the fevers from continued to typhoid. Hydrochloric acid is more often indicated in acute than in chronic diseases, and here it is that its effects of allaying irritation and acting as an antizymotic are marked. In *digestive disorders* it is especially applicable. The gastric juice itself contains this acid, and the cases requiring it are those in which the secretion of the natural acid is deficient. There may be nausea, vomiting, pyrosis, and stomatitis; greasy yellow, or brown eructations, with a bitter, unpleasant taste; and the breath is pungent and hot. These, together with the characteristic coloration of the membranes, point clearly to its use, whether it be a simple *indigestion* or advanced *dyspepsia*. *Intestinal indigestion*, *fermentative diarrhæa*, *catarrhal intestinal disorders of children*, *malignant dysentery*, or any bowel disorder with deep-red membranes and tendency to blood disintegration, are alike improved under its use. *Pneumonia*, *rheumatism*, and *diphtheria* occasionally need hydrochloric acid. In *phthisis* it checks septic changes and acts as a tonic in the processes of digestion and assimilation. *Purpura hemorrhagica*, *hepatic disorders*, and *erysipelas* are benefited by it when indicated. Webster calls attention to the fact that when the dark-red coloration of membranes is due to cardiac complications or other conditions tending to imperfect decarbonization of the blood, the mere indication, "red coloration," does not hold good. As specifically employed, the dose of the acid (pure or diluted) should be such that the aqueous dilution should be pleasantly sour; it may be sweetened if desired. The dose of diluted hydrochloric acid varies from 10 drops to a fluid drachm, which should be added to 4 or 6 fluid ounces of water, and sucked through a quill or glass tube, to prevent its injuring the teeth.

Specific Indications and Uses.—Deep-red, dry and contracted tongue, with a brownish coating; tongue contracted, with a central brownish stripe, or with a fissured, brownish coat; sordes; membranes dark-red; or the tongue is dark or dusky-red, moderately full and slick, having the appearance of a piece of spoiled beefsteak; pungent heat of skin, slow digestion, and nervous prostration.

ACIDUM HYDROCYANICUM DILUTUM (U. S. P.)—DILUTED HYDROCYANIC ACID.

FORMULA: (Absolute hydrocyanic acid) HCN. MOLECULAR WEIGHT: 26.98.

SYNONYMS: *Prussic acid*, *Acidum hydrocyanatum*, *Acidum borussicum*, *Cyanhydric acid*.

Diluted hydrocyanic acid is an aqueous solution containing 2 per cent, by weight, of absolute hydrocyanic acid ($\text{HCN}=26.98$) and 98 per cent of water (U. S. P.).

Source.—Scheele discovered this acid in 1782. It is contained in many trees and shrubs of the natural order *Rosaceæ*, principally in the sub-orders *Amygdalææ* and *Pomeææ*, where it is found in the seeds, barks, leaves and flowers, existing uncombined largely in the fluid portions of the plant. It is this acid which, in combination with benzaldehyde, gives to the almond and to peach seeds and leaves their pleasant and characteristic flavor.

Preparation.—"Potassium ferrocyanide, in coarse powder, twenty grammes (20 Gm.) [309 grs.]; sulphuric acid, eight cubic centimeters (8 Cc.) [180 Ml.]; water, sixty-five cubic centimeters (65 Cc.) [2 fl. 3, 95 Ml.]; distilled water, a sufficient quantity. Place the potassium ferrocyanide in a tubulated retort, and add to it forty cubic centimeters (40 Cc.) [1 fl. 3, 169 Ml.] of water. Connect the neck of the retort (which is to be directed upward), by means of a bent tube, with a well-cooled condenser, the delivery tube of which terminates in a receiver surrounded with ice-cold water, and containing sixty-five cubic centimeters (65 Cc.) [2 fl. 3, 95 Ml.] of distilled water. All the joints of the apparatus, except the neck of the

receiver, having been made air-tight by means of well-fitting corks, pour into the retort, through the tubulure, the sulphuric acid, previously diluted with twenty-five cubic centimeters (25 Cc.) [406 M.] of water. Gently mix the contents of the retort and then heat it in a sand-bath, so as to keep the liquid in brisk ebullition, until about one-half of its volume has passed over into the receiver. Detach the receiver, and assay a small portion of the contents by the method given below. Then add to the remainder so much distilled water as may be required to bring the product to the strength of 2 per cent, by weight, of absolute hydrocyanic acid. Diluted hydrocyanic acid may also be prepared, extemporaneously, in the following manner: silver cyanide, six grammes (6 Grm.) [93 gra.]; hydrochloric acid, five cubic centimeters (5 Cc.) [81 M.]; distilled water, fifty-five cubic centimeters (55 Cc.) [1 fl $\frac{3}{4}$, 426 M.]. Mix the hydrochloric acid with the distilled water, add the silver cyanide, and shake the whole together in a glass-stoppered bottle. When the precipitate has subsided, pour off the clear liquid. Diluted hydrocyanic acid should be kept in small, dark amber-colored, cork-stoppered vials, in a cool place"—(U. S. P.).

Wittstein gives the following formula for making diluted hydrocyanic acid, which forms quite a permanent acid, one that may be freely exposed to the light for ten or twelve weeks without any apparent change: to 16 ounces of distilled water add 4 ounces of ferrocyanide of potassium; when dissolved, add a mixture, cold, of 12 ounces of alcohol, specific gravity 0.840, with 8 ounces of sulphuric acid. Let this mixture stand for 24 hours, with occasional agitation. By means of a strainer separate the crystalline precipitate, introduce the clear liquid into a retort which has an inch in depth of its bottom covered with clean quartz-sand, in order to check the thumping during the distillation, and distill off 20 fluid ounces. Reduce the distillate to the proper strength by the appropriate tests.

Description and Tests.—Concentrated or anhydrous hydrocyanic acid is not used in medicine. The medicinal acid is a clear fluid, having a peculiar, penetrating, diffusive odor, and a peculiar, rather disagreeable taste, both the "odor and taste resembling those of bitter-almonds"—(U. S. P.). It is very poisonous (on which account it should be tasted with great caution), is very volatile, imparts a slight red tinge to litmus paper which is not permanent, and is decomposed by the action of light, giving rise to a black substance, paracyanogen. Vials in which it is placed should be small, and of a dark-amber color, and well-stopped with cork. It should always be kept in a cool situation. "It is completely volatilized by heat"—(U. S. P.). If the acid strongly reddens litmus it contains some other acid; if it be sulphuric acid, a solution of nitrate of barium, which occasions no precipitate in the pure acid, will yield a white deposit of sulphate of barium, insoluble in nitric acid. If hydrochloric acid be present, nitrate of silver forms a white deposit of chloride of silver insoluble in boiling nitric acid, whereas the white cyanide of silver is soluble in nitric acid at 100° C. (212° F.). It is soluble in water, ether, and alcohol in all proportions. Hydrocyanic acid may be known: 1. By its peculiar odor; 2. by its forming prussian blue when, after having accurately saturated it with caustic potash, a solution of sulphate, and of chloride of iron is added to it, and to the precipitate thus procured some diluted sulphuric or hydrochloric acid be added; 3. the white precipitate of cyanide of silver, caused by the addition of a solution of nitrate of silver, is soluble in boiling concentrated nitric acid; 4. a very delicate reaction is as follows: place a few drops of the suspected liquid upon a watch glass, add a few drops of ammonia and yellow ammonium sulphide, warm on a water-bath to decompose the excess of the latter; when the liquid is colorless, render faintly acid with hydrochloric acid and add some ferric chloride; a blood-red coloration of ferric sulphocyanide will appear if HCN was originally present. The following is Schönbein's test for the millionth part of a drop of hydrocyanic acid in water, or in vapor in the atmosphere: dissolve 3 grammes (46½ troy grains) of guaiac resin in 100 grammes (1543½ troy grains) of rectified alcohol. Moisten enough filtering-paper in this solution to absorb the whole of it; the paper should remain white. Also make a solution of sulphate of copper 1 decigramme (1½ troy grains) to 50 grammes (771½ troy grains) of distilled water. When it is desired to use this test, cut off a small strip of this paper,

moisten it with the solution of sulphate of copper, and place it in contact with the suspected fluid or vapor, and if hydrocyanic acid be present, the paper becomes blue instantly.

Hydrocyanic acid is incompatible with the mineral acids, the salts of iron, the sulphides, chlorine, the oxides of mercury, of antimony, nitrate of silver, etc. Light decomposes it, hence it should always be kept in bottles that are darkened or covered so as to prevent the rays of light from passing into them. In using this acid medicinally, care should always be taken to procure the *diluted* preparation. Scheele's medicinal hydrocyanic acid is stronger than the official diluted acid of the *United States Pharmacopæia*, as 2 is to 5. A very weak hydrocyanic acid is less liable to decomposition than the stronger preparations, hence it is that such preparations as Scheele's (above) is unfitted for medicinal use, on account of the readiness with which it loses strength. Prof. J. U. Lloyd has shown that a hydrocyanic acid made with a portion of alcohol will retain its properties unaltered and without apparent loss, for at least three years. "If to 1 Cc. of the acid, rendered alkaline by potassium hydrate T.S., a few drops, each, of ferrous sulphate T.S. and ferric chloride T.S. be added, and the mixture then acidulated with hydrochloric acid, a blue precipitate will be formed. To ascertain the percentage strength, mix in a flask (of the capacity of about 100 Cc.) 0.27 Gm. of hydrocyanic acid (obtained by distillation as above directed) with sufficient water and magnesia to make an opaque mixture of about 10 Cc. Add to this 2 or 3 drops of potassium chromate T.S., and then, from a burette, decinormal silver nitrate V.S., until a red tint is produced which does not again disappear by shaking. Each cubic centimeter of silver nitrate V.S. used indicates 1 per cent of absolute hydrocyanic acid. After ascertaining the strength of the distillate, dilute it with distilled water so as to bring it to the strength of 2 per cent of absolute acid. Lastly, test the finished product again, when 1.35 Gm. of it should require, for complete precipitation, 10 Cc. of decinormal silver nitrate V.S."—(*U. S. P.*).

Action and Toxicology.—Prussic acid is one of the deadliest of known poisons. In small doses it produces in man, salivation, faucial irritation, epigastric warmth, bitter, hot taste, dizziness, light feeling in head, tinnitus, pain in head, numbness, vertigo, dusky countenance, drowsiness, staggering gait, præcordial constriction, and the pulse either increased with palpitation, or decreased in action. From such doses ulceration of the mouth, and salivation have occurred. In poisonous doses its effects are very rapid. When a half ounce of the ordinary solutions (2 to 4 per cent) is taken, the symptoms usually commence with swallowing, or quickly thereafter. The symptoms are rarely delayed beyond *one or two minutes* (Taylor). Faintness, vertigo, or more commonly insensibility, at once take place. Then follow fixation and glistening of the eyes, with dilatation of the pupils which light fails to affect, flaccid limbs, cold skin with clammy perspiration, dusky, turgid countenance, hot head, convulsive breathing at long intervals (appearing dead during the intervals), pulse imperceptible, involuntary evacuations, respiration slow, deep, and gasping, usually convulsive, though occasionally sobbing or heaving, and if there be profound coma, the breathing is stertorous. Usually in fatal cases, relaxation rather than convulsions, is the rule, though in occasional cases convulsions, or rigidity with set jaws, have been observed. The eyes retain their peculiar luster after death, and the congested state of the gastric membranes, as well as the engorgement of blood in the deeper veins, with empty arteries, and the purplish hue of the skin, are among the post-mortem appearances.

The smallest dose which has produced death is that equivalent to $\frac{1}{10}$ grain of the anhydrous acid, or 45 minims of the official solution. Time, 20 minutes; a healthy, adult female. The smallest fatal dose is therefore assumed to be 50 minims of the solution [2 per cent] (Taylor). Taylor compares the death to that of lightning, the patient either dies quickly, or recovers altogether. Seven drachms of the solution killed a physician in four or five minutes; and a single drop of the pure acid in the eye or throat of a strong dog killed the animal in a few seconds. The strong odor of bitter almonds is given off from the poisoned patient before and after death. Death may result from either respiratory or cardiac paralysis. If death does not take place in one hour, the patient will

probably recover. The effects of potassium cyanide closely resemble those of prussic acid. In cases of poisoning by hydrocyanic acid, there is seldom time to administer an antidote; but when life is not extinct, we may confidently rely on the antidotes we possess. The theoretical antidote is ferrous sulphate. The best is that proposed in the *Lancet* for 1844, Vol. II., p. 41, by Messrs. T. & H. Smith, of Edinburgh, viz.: In a fluid ounce or two of water, dissolve carbonate of potassium 20 grains, and cause the patient to swallow it; and, immediately following this, administer a solution of sulphate of iron 10 grains, tincture of chloride of iron a fluid drachm, in a fluid ounce of water. This will convert about 2 grains of the strong acid into an insoluble prussian blue. While these are being prepared, the symptoms already produced will be best combated by ammonia inspired from a sponge, or taken, diluted, internally; by chlorine water, used by inhalation, and internally, in teaspoonful doses, diluted with water; cold affusion, dashing the water or pouring it from a height, more especially on the head and along the spinal column; and also artificial respiration and electricity.

Medical Uses and Dosage.—When largely *diluted* (2 per cent), it has been employed in medicine as a sedative to subdue *spasm*, and allay *nervous irritability*. It has been used to relieve severe *vomiting* and *purging*, to check *colliquative diarrhœa*, to cure *pertussis* and *spasmodic coughs*, *asthma*, *hysteria*, *chorea*, *dyspepsia* connected with morbid irritability of the stomach, etc.; also externally in several diseases of the skin. It has likewise been found beneficial in the *cough of consumptives*, *cardiac palpitations*, *hypertrophy of the heart*, and in *difficult breathing*. It is useful in *angina pectoris*, but not so valuable as amyl nitrite or glonoin. Minute doses relieve *congestive headache*. But, from its volatility, its variability of strength, and its proneness to decomposition, it will very frequently disappoint the expectations of the practitioner, either by inducing fatal symptoms, or being wholly inert. The dose of the diluted acid is from 1 to 3 drops in water, mucilage or syrup.

Specific Indications and Uses.—"Elongated and pointed tongue with reddened tip and edges; uneasy sensations in the stomach" (Scudder), nausea, vomiting, gastric irritation and pain; vertigo; angina pectoris; cough of phthisis (palliative); gastric cough with scanty secretions. In the specific use of this drug, 5 minims of the official acid (2 per cent) are added to 4 fluid ounces of water, and teaspoonful doses of the mixture administered every 2 or 4 hours.

ACIDUM HYDROFLUORICUM.—HYDROFLUORIC ACID.

FORMULA: HF. MOLECULAR WEIGHT: 20.

SYNONYMS: *Hydrogen fluoride*, *Fluorhydric acid*, *Acidum fluorhydricum*.

Source and History.—Scheele discovered an impure hydrofluoric acid in 1771. It was subsequently obtained pure by Gay-Lussac and Thénard in 1808. Hydrofluoric acid is a derivative of the element fluorine, which occurs in *fluor-spar* (calcium fluoride) and other minerals, as for instance *cryolite* ($\text{Al}_2\text{F}_6\text{Na}_3$). It is present to a slight extent in the bones of mammals, as fluoride of calcium, existing in human bone, according to Berzelius, to the extent of 2 parts in 100. It is also a constituent of the enamel of the teeth, and is found to some extent in both drinking and mineral waters.

Preparation.—The greatest care is necessary in the preparation of this acid. It is recorded that Prof. Nickles, of Naples, lost his life from the accidental inhalation of hydrofluoric acid vapors. To prepare it, powdered fluor-spar may be gently heated with sulphuric acid in a lead or platinum retort, and the resultant gas, which exhibits great avidity for moisture, may be conducted into lead or platinum receivers containing cold distilled water, the receptacles being kept very cool by immersion in a cold bath. *Cryolite* may be used in place of *fluor-spar*, but either should be free from silica.

Description.—Hydrofluoric acid of commerce is a solution of hydrofluoric acid gas in water, in which it is extremely soluble. It is a thin, colorless, liquid, emitting exceedingly dangerous vapors. The gas (in the presence of moisture only), or the aqueous solution, actively attacks glass on account of its strong attraction for silica, with which it forms silicon fluoride (SiF_4), and hydrofluosili-

cates of the bases contained in the glass. For this reason it is extensively used for etching upon glass. To illustrate its action a piece of glass may be coated with wax or paraffin, into which a design is scratched with a needle, leaving the surface of the glass free where traced. The glass may then be laid face downward over a mixture of equal parts of powdered fluor-spar and sulphuric acid contained in a leaden vessel, and gently heated in the open air, being extremely careful not to inhale any of the fumes. The gas attacks the glass in those parts not coated with wax, and leaves, on the surface of the plate, an opaque impression of the figure drawn. On account of this action on glass, it must be kept in leaden or rubber bottles.

Action, Medical Uses, and Dosage.—This acid has an intensely irritating action upon the respiratory organs, may produce spasm of the glottis, and has caused death. Allowed to come in contact with the skin, it powerfully corrodes it, producing a deep sore very difficult to heal, and exhibiting an intensely painful, aching sensation. The vesicles produced by it should be immediately evacuated and treated with a dilute solution of caustic potash. Even the vapor will produce painful sores under the finger nails. Fermentation and putrefaction are powerfully restrained by even so dilute a solution as 1 in 3000. From the fact that etchers upon glass seemed remarkably free from phthisis, several French physicians attributed their exemption to the use of this acid in their work. A series of trials was made to determine its usefulness in this complaint. A special chamber (23 Cc.) was constructed by Dujardin-Beaumetz in which he exposed consumptive patients to the vapor of 1 grain of the acid diffused from a leaden vessel by means of a water bath. Expectoration was lessened and the appetite somewhat increased, but beyond this no good results were apparent. It has been prescribed in *phthisis*, *pertussis*, *asthma*, and *diphtheria*, but without success; also in aneurism to slow the arterial action. Woakes claims to have cured seventeen out of twenty cases of *goitre* with it. Large doses, 15 to 60 minims, were given, largely diluted, 3 times a day. Other adjuvant treatment was also employed and particularly injections of iodine, and it is but fair to presume that much of the benefit was derived from the adjuvant treatment. The fluorides relieve pain without proving narcotic, quickly cause loss of appetite and gastric derangement even in very small doses, and speedily act as non-depressing emetics.

ACIDUM HYPOPHOSPHOROSUM DILUTUM (U. S. P.)—DILUTED HYPOPHOSPHOROUS ACID.

Formula: HPH_2O_2 . **Molecular Weight:** 65.88.

A liquid composed of about 10 per cent, by weight, of absolute hypophosphorous acid ($\text{HPH}_2\text{O}_2=65.88$), and about 90 per cent of water (U. S. P.).

Preparation.—Hypophosphorous acid may be prepared from any of the hypophosphites which are soluble. The process of Moerk is as follows: Take calcium hypophosphite 69 parts, boiling water 450 parts. Solve. Crystallized oxalic acid 50.4 parts, boiling water 200 parts. Solve. Mix the two solutions, boil for one-half hour, cool, filter by means of cotton, and wash the precipitate with cold water. Finally evaporate the filtrate to 88 parts. This process yields a 60 per cent acid, and as diluted hypophosphoric acid of the Pharmacopœia contains but 10 per cent of absolute acid, it may readily be prepared by diluting the above 60 per cent acid to the desired strength by the addition of distilled water. The *National Formulary* directs its preparation as follows:

ACIDUM HYPOPHOSPHOROSUM DILUTUM (N. F.), Diluted hypophosphorous acid.—*Formulary number, 6:* "Potassium hypophosphite two hundred and eight grammes (208 Gm.) [7 ozs. av., 147 grs.]; tartaric acid three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; distilled water five hundred and eighty-eight grammes (588 Gm.) [1 lb. av., 4 ozs., 324 grs.]; diluted alcohol (U. S. P.) six hundred grammes (600 Gm.) [1 lb. av., 5 ozs., 72 grs.]. Dissolve the potassium hypophosphite in the distilled water, and the tartaric acid in the diluted alcohol. Mix the two solutions in a flask, cork the latter well, and put it aside in a cold place during twelve hours. Then carefully decant the liquid into a funnel, the neck of which contains a pellet of absorbent cotton, or, if necessary, pass the liquid through a

filter, care being taken that it shall not suffer loss by evaporation. Weigh the filtrate, which contains 10 per cent of hypophosphorous acid, in a tared capsule, and evaporate the alcohol by means of a water bath, at a temperature not exceeding 80° C. (140° F.). Then allow the liquid to cool, and add enough distilled water to restore the original weight of the filtrate. Preserve the product in well-stoppered bottles.

Note.—This acid is now official in the *U. S. P.*; but the formula is retained because it may be now and then convenient or necessary to make it. If a 50 per cent acid is required, the concentration may be cautiously continued until the desired percentage has been attained. A 50 per cent acid has a specific gravity of about 1.406 at 15° C. (59° F.).—(*Nat. Form.*).

Description and Tests.—The *U. S. P.* thus describes and gives tests for this acid: "A colorless liquid, without odor, and having an acid taste. Specific gravity about 1.046 at 15° C. (59° F.). Miscible in all proportions with water. When heated in a porcelain capsule, it evaporates, losing at first principally water, and becoming more concentrated. On further heating it decomposes, forming hydrogen phosphide which ignites, and phosphoric acid. The pasty residue finally reddens, ignites, and the last portions of phosphorus burn out at higher heat. From silver nitrate T.S. it reduces black metallic silver. When the acid is gently heated with copper sulphate T.S., a yellow precipitate of copper hydride falls, which rapidly assumes a reddish-brown color. The addition of hydrogen sulphide T.S. to the acid should produce neither a precipitate nor a coloration (absence of lead, etc.). If some of the acid be neutralized with ammonia water, separate portions of the liquid should not yield a precipitate with ammonium sulphide T.S. (absence of iron, etc.), nor with ammonium oxalate T.S. (absence of calcium); nor should more than a slight turbidity be produced by barium chloride T.S. (limit of phosphoric, sulphuric, oxalic and tartaric acids). Neither platinic chloride T.S. nor sodium cobaltic nitrite T.S. should produce more than a slight yellow turbidity in the diluted acid (limit of potassium). If 0.5 Gm. of diluted hypophosphorous acid be mixed with 7 Cc. of sulphuric acid and 35 Cc. of decinormal potassium permanganate V.S., and the mixture boiled for 15 minutes, it should require about 4.7 Cc. of decinormal oxalic acid V.S. to discharge the red color, corresponding to about 10 per cent of the absolute hypophosphorous acid. To neutralize 6.6 Gm. of diluted hypophosphorous acid should require about 10 Cc. of normal potassium hydrate V.S. (each cubic centimeter corresponding to 1 per cent of the absolute acid), phenolphthalein being used as indicator"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Reputed tonic in *nervous debility*, though seldom if ever used, except in combination with other tonic mixtures and syrups. The dose ranges from 10 to 60 minims.

ACIDUM LACTICUM (U. S. P.)—LACTIC ACID.

FORMULA: $\text{HC}_2\text{H}_3\text{O}_2$. **MOLECULAR WEIGHT:** 89.79.

SYNONYMS: *Isolactic acid, Oxypropionic acid, Ethylidene-lactic acid, Ethidene-lactic acid.*

"An organic acid, usually obtained by subjecting milk-sugar or grape-sugar to lactic fermentation; composed of 75 per cent, by weight, of absolute lactic acid [$\text{HC}_2\text{H}_3\text{O}_2=89.79$], and 25 per cent of water"—(*U. S. P.*).

Source and History.—Lactic acid is formed from milk-sugar by the process of "lactic fermentation" induced by the presence of casein. It is the acid principle of sour milk and is produced when vegetable and other tissues become soured, as in sauerkraut, or when beet juice, or rice-water are allowed to ferment, and it may also be obtained from refuse liquor produced in the manufacture of starch and the tanning of leather. It is found in natural form in the juice of the bittersweet (*Solanum Dulcamara*) (Wittstein), and occurs normally in some of the fluids of the body, notably the gastric juice; also in certain pathological conditions. That it exists in the gastric juice, however, is contradicted by Maly and others. This acid was first obtained from sour milk by Scheele in 1780. Berzelius discovered it in a modified form in meat juices in 1807 and named it *sarcolic*.

lactic acid, which, however, has been shown to be a combination of *paralactic* and *ethylenelactic acids*. These acids are isomeric with the lactic acid of fermentation, but behave differently toward polarized light. The greater portion of lactic acid comes to us from Germany, though a considerable amount is now prepared in the United States. Alcohol, mannit, a gum, and several other acids may be obtained in making lactic acid.

Preparation.—This acid is usually prepared by allowing milk-sugar to digest for a few weeks, in the sunlight, at a temperature of about 30° C. (86° F.), in a mixture of milk, rotten cheese, and chalk. The casein of the cheese induces lactic fermentation, the resulting acid being neutralized by the calcium compound, forming calcium lactate. The calcium salt is then crystallized, decomposed with oxalic acid by which calcium oxalate is formed, and lactic acid is liberated. At no time should the temperature fall below 20° C. (68° F.), or rise above 40° C. (104° F.), for at the former the formation of the acid is retarded and at the latter a certain amount of butyric acid is produced.

A more rapid process than that customarily followed, and one which gives a greater yield, is that of Kiliani (1882). Cane sugar is converted into invert sugar by dissolving in two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.] of water, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.] of cane sugar, and boiling it with ten cubic centimeters (10 Cc.) [162 M.] of sulphuric acid. To this is gradually added four hundred and fifty cubic centimeters (450 Cc.) [15 flz., 104 M.] of a solution of equal parts of sodium hydroxide and water. This is heated to 60° C. (140° F.), or 70° C. (158° F.), until it no longer reacts, or gives but a very faint greenish color, with Fehling's test solution. Sulphuric acid is then added to neutralization, sulphate of sodium crystallizes, and 93 per cent alcohol is added until the remainder ceases to throw down a precipitate. Then over a sand-bath one-half of the alcoholic solution is boiled and neutralized with carbonate of zinc, and, while boiling hot, filtered, added to the other half, and allowed to cool. Lactate of zinc at once begins to crystallize, requiring about 36 hours for completion. The crystals are expressed and recrystallized. This salt is then treated with oxalic acid, and lactic acid results. When well-soured sauerkraut is boiled with zinc carbonate, lactate of zinc is formed.

ACIDUM LACTICUM DILUTUM (Br.) *Diluted lactic acid*: "Lactic acid 3 fluid ounces (Imp.); distilled water, q. s. to make 1 pint (Imp.). Mix"—(*Brit. Phar.*).

Description and Tests.—Pure lactic acid is colorless and odorless. The official preparation is "a colorless, syrupy liquid, odorless, of a purely acid taste, and absorbing moisture on exposure to damp air. Specific gravity, about 1.213 at 15° C. (59° F.). Freely miscible with water, alcohol, or ether; insoluble in chloroform, benzin, or carbon disulphide. Lactic acid is not vaporized by a heat below 160° C. (320° F.); at a higher temperature it emits inflammable vapors, and is finally dissipated. 5 Gm., after combustion, should not leave more than 0.05 Gm. of fixed residue. Lactic acid has a strongly acid reaction"—(*U. S. P.*).

Albumen is coagulated by it. Treated with nitric acid it yields oxalic acid. It gives rise to the lactates, and when treated with chromic acid, acetic and formic acids result. Heated to 150° C. (302° F.), it is converted into the anhydride, *lactide* ($C_4H_4O_3$ —concrete lactic acid), a crystalline solid. When painted upon substances it dries to form a smooth varnish which gradually absorbs moisture from the air.

"On adding some potassium permanganate to a mixture of equal volumes of lactic and sulphuric acids, and gently heating, the odor of aldehyde will become perceptible. 10 Cc. of a 1 per cent aqueous solution of the acid should not be rendered opalescent by the addition of 1 Cc. of silver nitrate T.S. (limit of chloride). 10 Cc. of a 10 per cent aqueous solution should remain unaffected by the addition of 1 Cc. of barium chloride T.S. (absence of sulphate), or by 1 Cc. of copper sulphate T.S. (absence of sarcolactic acid), or after supersaturation with ammonia by 1 Cc. of ammonium sulphide T.S. (absence of iron, lead, etc.). On adding a few drops of lactic acid to 10 Cc. of hot alkaline cupric tartaric V.S., no red cuprous oxide should be separated (absence of sugars). If a small portion of the acid be heated with an excess of zinc carbonate, the mixture dried at 100° C. (212° F.), and then extracted with absolute alcohol, upon evaporation of the latter no sweet residue should remain (absence of glycerin). On mixing equal

volumes of lactic and colorless, concentrated sulphuric acids in a small, clean, glass-stoppered vial, the mixture should not acquire a tint deeper than a pale straw-color (absence of more than traces of organic impurities). To neutralize 4.5 Gm. of lactic acid should require 37.5 Cc. of potassium hydrate V.S. (each cubic centimeter corresponding to 2 per cent of absolute acid), phenolphthalein being used as indicator"—(U. S. P.).

Action, Medical Uses, and Dosage.—Lactic acid is a normal constituent of the gastric juice, and to its excess in the system has been attributed the cause of rheumatism; but whether it is the cause or a result has not yet been definitely determined. Very large doses are reputed hypnotic (Mendel).

Lactic acid quickly dissolves oxalate of calcium and phosphate of calcium, especially that which is contained in the bones, and hence has been recommended in oxalic and phosphatic urinary deposits. It has not, until quite recently, been much employed in medicine in its uncombined state, but has been used in the preparation of lactate of iron and lactate of quinine. According to Pereira this acid was introduced into medicine by Magendie, who suggested its employment in *dyspepsia* and in *phosphatic urine*. It has more recently been advised in *gout*. The dose is from half a drachm to 2 drachms, in sweetened water, or in the form of lozenges. It is better to take the acid during or immediately following meals. Added to pepsin, as prepared for therapeutical use, this acid renders it still more valuable as a solvent of the food received into the stomach. According to Bricheteau and Adrian, the false membranes of *diphtheria*, *croup*, *pseudomembranous bronchitis*, etc., are soluble in a solution of lactic acid, forming a translucent liquid with almost imperceptible fragments of a gelatiniform substance floating upon its surface and looking like froth, while acetic, citric, formic, and chromic acids have no such action. They recommend in *croup*, *diphtheria*, etc., a gargle composed of lactic acid 5 parts, water 100 parts, and orange syrup 30 parts; in conjunction with the use of the same, minus the syrup, in the form of spray thrown upon the affected parts.

Lactic acid has been used topically in ulcerated states of the nasal fossæ and in *suppurative otitis*, though in the latter disease the results are not commensurate with the irritation of the external canal which it occasions. In *caries* of the aural bony structures it has been advised, but it is open to the same objection mentioned above. It fails to destroy dense granulations of the tympanum. Webster (*Dynam. Therap.*) declares it second only to acetic acid in obstinate *tinea versicolor*, and states that it does not attack the true skin. "*Liver spots*" and *ephelides* are said by him to be removed by the application of the concentrated acid, the procedure to be repeated until the epidermis and underlying pigment are removed in such a manner as to avoid cicatrization. The lesions are then dressed with mild zinc ointment or a similar dressing. Epithelial excrescences, such as *warts*, *horny growths*, and *tylosis* of the palms and soles, are removed by the continued application of the acid with a camel's-hair pencil.

The most important use of this remedy, however, is in *gastro-intestinal affections*. Where an acid is indicated and the digestive powers are feeble this acid should be preferred to hydrochloric and other acids. It may therefore be employed in feeble digestion and even in advanced *dyspepsia*. It is a well-known fact that delicate stomachs that can scarcely retain any other food, kindly receive buttermilk and coagulated or "clabbered" milk, and this often forms an excellent means of administration. The irritable stomach with evident lack of, or but scanty secretion of gastric juice, clearly points to its use. Its action in *infantile diarrhœa* with a painful and irritable stomach and the passage of green evacuations is most positive. It should be given in water that has been boiled and may be sweetened if desired. The dose should be regulated so that the little patient receives from $\frac{1}{2}$ to 1 drop at a dose. The dose of lactic acid may range from a half drop to a half ounce in 24 hours. The small doses, from one-half drop to 5 drops, are those which act specifically.

Specific Indications and Uses.—Gastric irritation with thirst, deep-red tongue, and diarrhœa with green stools, itching skin, and cutaneous eruptions, especially when arising from gastric disturbances.

ACIDUM NITRICUM (U. S. P.)—NITRIC ACID.

FORMULA: HNO_3 . **MOLECULAR WEIGHT:** 62.89.

SYNONYMS: *Aqua fortis*, *Azotic acid*, *Spirit of nitre*, *Acidum nitri*, *Acidum azoticum*, *Spiritus natri acidus*.

"A liquid composed of 68 per cent, by weight, of absolute nitric acid (HNO_3 , =62.89) and 32 per cent of water. Nitric acid should be kept in dark amber-colored, glass-stoppered bottles"—(U. S. P.).

Source.—This acid was known to the ancient alchemists as "Aqua fortis." It was prepared by Geber, in the eighth century, by distilling a mixture of niter, blue vitriol, and alum. Cavendish determined its composition in 1785. Nitric acid is present to a slight extent in a moist atmosphere, and particularly in rain-water falling during a thunder-shower. It is found in the fluids of some plants, and occurs in large quantities in alkaline combination where the oxidizing process of "nitrification" converts the nitrogen of decaying animal and vegetable tissues into nitric acid. In this silent but continuous manner large deposits of nitrates are formed in the earth, such as the "niter beds" of India and along the coast of Chili and Peru. Spring-water or surface well-water which has filtered through soil containing decomposed animal matter often contains nitrates in solution, and is unfit for drinking purposes.

Preparation.—Nitric acid is generally procured on a large scale by submitting to distillation either nitrate of potassium or of sodium with sulphuric acid, in an apparatus somewhat similar to that used in the distillation of oil of vitriol. The sodium or potassium unites with the sulphuric acid to form a sulphate, while the nitric acid is liberated in the form of gas, which is passed into a vessel of water, this fluid absorbing it and acquiring acid properties. According to Deville, dry or uncombined nitric acid (nitrogen pentoxide, or nitric anhydride N_2O_5) may be obtained by decomposing dry nitrate of silver by dry chlorine gas. It forms large, brilliant, colorless crystals, belonging to the right-rhombic prismatic system, which fuse at 24.4°C . (85°F .) and boil at 45°C . (113°F .).

Description and Tests.—Nitric acid is met with of various strengths, as follows:

I. **MONOHYDRATED NITRIC ACID, Hydrate of nitrogen.**—This, the strongest of the nitric acids, has been abandoned, owing to the difficulties attending its preparation, and to its instability. (For detailed description of it see *Am. Disp.*, 11th ed.)

II. **CRUDE NITRIC ACID.**—This acid is frequently called *Aqua fortis*, and is of two strengths—*Single aqua fortis* (spec. gr., 1.21) and *Double aqua fortis* (spec. gr., 1.37). It is colorless, or yellowish, and is employed in industrial processes, and occasionally in preparing certain pharmaceutical preparations.

III. **ACIDUM NITRICUM (U. S. P.), Nitric acid**, according to the *United States Pharmacopœia*, contains 68 per cent of absolute nitric acid. It colors the skin and nails yellow, and if long enough in contact with the tissues it will produce deep and slowly-healing sores. "A colorless, fuming liquid, very caustic and corrosive, and having a peculiar, somewhat suffocating odor. Specific gravity, about 1.414 at 15°C . (59°F .). It boils at 120.5°C . (248.9°F .), and is completely volatilized. It dissolves copper, mercury, silver, and other metals with evolution of red vapors, and stains woolen fabrics and animal tissues a bright yellow. Heated with indigo T.S., it discharges the blue color of the latter. Even when highly diluted, it shows an intensely acid reaction with litmus paper.

"If 1 Cc. of nitric acid be slightly supersaturated with ammonia water, no precipitate should be formed (absence of iron, or much lead); nor should the liquid assume a blue tint (copper); nor should the further addition of a few drops of colorless ammonium sulphide T.S. produce any coloration or precipitate (lead, iron, copper, etc.). On diluting some of the acid with five times its volume of water, a portion of this liquid, when gently heated and treated with freshly-prepared hydrogen sulphide T.S., should not show a colored precipitate (absence of lead, arsenic, copper); nor should any precipitate be produced in other portions of the diluted acid by barium chloride T.S. (absence of sulphuric acid), or by silver nitrate T.S. (absence of hydrochloric acid). If the diluted acid be shaken

with a few drops of chloroform, the latter should remain colorless (absence of iodine or bromine), even after introduction of a small piece of metallic zinc (absence of iodic or bromic acid). To neutralize 3.145 Gm. of nitric acid should require 34 Cc. of normal potassium hydrate V.S. (each cubic centimeter corresponding to 2 per cent of absolute acid), phenolphthalein being used as indicator"—(U. S. P.).

The presence of nitric acid or nitrates in a liquid may also be ascertained by carefully adding about one-half its volume of pure sulphuric acid, and when the mixture is cold, a layer of solution of ferrous sulphate; if nitric acid be present a purplish or brownish color will appear where the two liquids meet.

IV. **ACIDUM NITRICUM DILUTUM** (U. S. P.), *Diluted nitric acid*.—Take "nitric acid, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; distilled water, five hundred and eighty grammes (580 Gm.) [1 lb. av., 4 ozs., 201 grs.]; to make six hundred and eighty grammes (680 Gm.) [1 lb. av., 7 ozs., 481 grs.]. Mix them. Keep the product in dark, amber-colored, glass-stoppered bottles. Diluted nitric acid contains 10 per cent, by weight, of absolute nitric acid. Specific gravity, about 1.057 at 15° C. (59° F.). It corresponds in properties to nitric acid (see *Acidum Nitricum*), and should conform to the same reactions and tests. To neutralize 6.29 Gm. of diluted nitric acid should require 10 Cc. of normal potassium hydrate V.S. (each cubic centimeter corresponding to 1 per cent of absolute acid), phenolphthalein being used as indicator"—(U. S. P.).

V. **FUMING NITRIC ACID**, *Acidum nitricum fumans*, *Nitroso-nitric acid*, *Acidum nitroso-nitricum*.—This acid, which is produced when a less amount of sulphuric acid and greater heat is employed than is required for the production of nitric acid, is a mixture of HNO_3 with varying amounts of the lower oxides of nitrogen. It is a brownish-red fluid, giving off suffocating, brown-red fumes. It has a specific gravity ranging from 1.45 to 1.50. In attempting to remove the stopper from the container great care should be observed that a portion of the acid is not forcibly expelled with the fumes. It should always be kept in a cool situation. A preparation, known as *commercial nitrous acid* is a weaker, though similar, acid, being colored red by nitrogen tetroxide in varying amounts, and consisting largely of nitric acid.

Action and Toxicology.—Nitric acid internally in medicinal doses long-continued, or in nitric-acid baths, may produce the following symptoms: Increased appetite at first and diuresis; white-coated tongue; mouth at first dry, and afterward abundantly bathed in saliva, with loosened and aching teeth, and spongy and bleeding gums; the dental enamel may be corroded. Foul breath, feverishness, headache, dyspepsia, intestinal colic, general debility, and bowel disorders, particularly constipation, may follow. The fumes inhaled are fatal, producing congestion, hemorrhage, and œdema of the breathing passages, with dyspnoea as the chief symptom. Mr. Haywood (1854), an English chemist, lost his life in this manner from the breaking of a carboy containing nitric and sulphuric acids. He died in eleven hours. Two firemen (1890) lost their lives from inhaling the nitrous fumes from a broken container of the acid during a fire. The fumes from batteries charged with the acid may poison in poorly-ventilated rooms. When swallowed, without dilution, nitric acid proves fatal; the same means may be employed to counteract its effects, as named for hydrochloric acid. The smallest amount which has produced death is 2 drachms, death occurring in 36 hours. Infants might be killed by a few drops, provided it came in contact with the larynx. The most rapidly occurring case of death took place in the usual manner in 1½ hours; the slowest case died from exhaustion in eight months after its ingestion. Death usually results inside of 24 hours. (See Taylor, *Med. Juris.*). Fatal doses are immediately followed by intense, burning pain in throat and œsophagus, reaching to the stomach; gaseous eructations, abdominal swelling; violent emesis of fluids and solids, mixed with strongly acid, yellowish shreds of mucus, and dark-brown, altered blood. Great tenderness of the abdomen is felt. The oral membranes are soft and white, turning to yellow or brown. The teeth are also white or yellowish, and the dental enamel corroded. Viscid mucus fills the mouth, and swallowing or speaking is extremely difficult. The tongue is swollen and yellow, and the tonsils enlarged. Obstinate constipation ensues, and liquids increase the pain and vomiting. The pulse becomes quick, small, and

irregular, the surface cold, and shivering takes place. A light stupor, from which the sufferer may easily be aroused, supervenes, and as a rule the intellect is unimpaired to the last. Should the fumes have been inhaled also, pneumonia complicates the case. After death the parts with which the acid came in contact exhibit shades varying from white to yellow and brown. The throat and trachea and lungs are congested and inflamed. The cesophageal membrane is yellow or brown, soft, and readily detachable in long shreds. The stomach shows the greatest damage, and though so soft as to break down under the faintest pressure, singularly no cases of perforation have yet been observed. The gastric membrane is partially inflamed, and exhibits patches of a yellow, brown, green, or black color. Such changes may be observed also in the duodenum, though only redness may be apparent.

Medical Uses and Dosage.—As an internal remedy nitric acid has a wide application. Discrimination, however, must be exercised in its use. The conditions under which it exhibits its selective action have been thus pointed out by Prof. Scudder: "If the tongue, whether pale, rose-red, or deep-red, presents a violet haze, we have an indication for nitric acid. We will notice the same violet haze wherever the blood comes to the surface in the capillary circulation. I think we get the most decided results when the mucous membranes are moderately red. Do not mistake the deep, solid purple of the mucous membranes we see sometimes for this violet haze, for here the irritable stomach very frequently presents the red tip and edges of tongue, and sometimes elongated papillæ"—(*Spec. Med.*, p. 189). Bearing out these indications, it has been very successfully used in *pneumonia*, *continued* and *typhoid fevers*, *typhoid dysentery*, and *malarial headache*. In *chronic ague* it has equalled cinchona in proper cases. Quinine sulphate dissolved in a few drops of nitric acid and diluted with water forms an excellent combination in some *malarial disorders*. In *stomach troubles* with irritability and enfeebled action it often benefits. Impaired nutrition, with slow and imperfect breaking down of effete matter and failure of excretion, often indicate nitric acid. Nitric acid has long been regarded refrigerant, expectorant, and antisiphilitic. A refreshing acidulous draught is formed by making a very dilute, sweetened, solution of nitric acid, which is useful in *fevers*, especially when there is a disposition to prostration or putrescency; it has likewise been recommended in *hepatic* and *siphilitic affections*. Dr. Gibbs recommended the following mixture as very valuable in *whooping-cough*: Take of diluted nitric acid, 12 fluid drachms; compound tincture of cardamon, 8 fluid drachms; simple syrup, 3½ fluid ounces; water, 1 fluid ounce. Mix. For a child one or two years old, a teaspoonful may be given every hour or two, washing the mouth out immediately after with some alkaline solution to prevent the teeth from being injured. That it is a positive remedy for some cases of *whooping-cough* is well attested by many practitioners. The indications will lead to the proper cases. Undoubtedly its radical, combined with sanguinarine, forming the nitrate, plays an important part in controlling *explosive coughs* having their origin in some derangement of the medulla. A severe case of this kind of two years' standing, and for the relief of which the patient had taken a trip to Oregon and remained awhile, was promptly cured by one prescription, as follows: R Nitric acid, gtt. x; sanguinarine nitrate, gr. j; specific drosera, gtt. x; water, fl.℥iv. Mix. Sig: A teaspoonful every 2 hours. Hope's mixture for *diarrhœa* and *dysentery* is composed as follows: Nitrous acid (or *double aqua fortis*), half a fluid drachm; camphor water, 4 fluid ounces; mix, and add laudanum, 40 M. The dose is a tablespoonful every 2 hours. Ten or 20 drops of the acid added to a pint of water forms a useful wash for sloughing and other ill-conditioned *ulcers*, and in various *chronic eruptions*, *porrigo of the scalp*, etc. Concentrated nitric acid has been used externally for several purposes, as the destruction of *warts*, cauterization of *poisoned wounds*, *stings*, *bites*, and in *phagedenic ulcerations*, in which the acid should be brought in contact with the living surface. I have also found it very useful in removing *pterygium*, and *ulceration of the os uteri*, *fiatula in ano*, *siphilitic ulceration of the throat*, etc., applied daily, or every 2 or 3 days, by means of a pine wood portecaustic, first introduced to the profession by Prof. A. J. Howe, M. D.

In the treatment of *piles*, nitric acid is said to be very efficacious; the small tumors may be destroyed by a single application of it, while the larger may

require two or three applications. If the tumors can not be extruded from the anus, a speculum must be used. The acid may be applied by a bit of sponge not larger than a grain of wheat, attached to a gold or glass probe. The severe pain which usually follows may be relieved by morphine, exhibited internally, and lard, or opiate suppositories applied locally. If too much acid has been applied, extending to contiguous parts, and causing unnecessary pain, it may be neutralized by applying a piece of sponge or cotton saturated with soda or potassa. Some claim greater certainty for this method than by excision or ligation.

For several years past I have used nitric acid as a local application to *chancre*. It must be applied while the chancre is in the pustular form and unbroken, and before the virus is acted upon by the oxygen of the atmosphere, and consequently previous to its absorption into the system. As soon as the pustule is discovered, the physician will open it and apply several drops of undiluted nitric acid to it, thus destroying the virus at once and curing the disease in a few minutes. The pain occasioned is hardly noticed by some patients. Sometimes, I subsequently wash the ulcer with the tincture of chloride of iron, which is one of the best local applications to a chancre. No other treatment is required, unless for the purpose of allaying the patient's fears. Since having introduced this employment of the acid to the profession, many have employed it, and with uniformly successful results (J. King). The improbable claim of curing *albuminuria* and "*Bright's disease*" (an uncertain complaint) with daily diluted injections of this acid per rectum is made by a Rochester, N. Y., physician. Upon the skin this acid is said to resemble thuja in its power over *condylomata*, *anal fissure*, and *sores* about the body outlets. Ringer declares that "small syphilitic warts and condylomata are painlessly and surely dispersed by the constant application of a dilute wash (1 or 2 drachms of diluted nitric acid to 1 pint of water)." Nitric acid applied with a broom-splint may be used to destroy large *granulations* and *polypi* in the tympanic cavity (Foltz). Nitric acid is never given internally unless very much diluted. Its dose is from 1 to 20 (strong acid) or 1 to 50 (diluted acid) drops in 4 or 6 fluid ounces of water; it should be sucked through a quill or glass-tube, to prevent its injuring the teeth, and the mouth should be rinsed with an alkaline solution immediately after each dose. For its specific use Prof. Scudder directs: R Nitric acid, gtt. xxx; simple syrup, fl̄ iv. Mix. Dose, a teaspoonful every 8 hours.

Specific Indications and Uses.—The pale, rose-red, or deep-red tongue, with a violet haze, seemingly like a transparent color over red; usually with moderately red membranes (Scudder); harsh, explosive cough of medullary origin; cases of imperfect waste with foregoing indications.

Liquid Glue.—When nitric acid is added to a solution of glue it prevents it from forming a jelly, and makes what is called a liquid glue, which is very convenient for cabinet-makers, joiners, paste-board workers, toy-makers, etc., inasmuch as it is applied cold. The liquid glue is made by taking 2½ pounds of good glue, and dissolving it in 2½ pints of water, in a glazed pot over a gentle fire, or, still better, in the water-bath, stirring it from time to time. When all the glue is melted, pour in, in small quantities at a time, of nitric acid specific gravity 1.32, 7 ounces avoirdupois. This addition produces an effervescence, owing to the disengagement of hyponitrous acid. When all the acid is added, remove the vessel from the fire, and allow it to cool. This preparation preserves nearly all the primitive qualities of the glue, may be kept in an open vessel for years, without undergoing any change, and will be found very convenient in chemical operations; gases may be preserved by it by covering strips of linen with it.

ACIDUM NITROHYDROCHLORICUM (U. S. P.) —NITROHYDROCHLORIC ACID.

SYNONYMS: *Nitromuriatic acid*, *Acidum nitromuriaticum*, *Acidum chloronitrosum*, *Aqua regia*, *Aqua regis*.

Preparation.—"Nitric acid one hundred and eighty cubic centimeters (180 Cc.) [6 fl̄, 42 M]; hydrochloric acid, eight hundred and twenty cubic centimeters (820 Cc.) [27 fl̄, 849 M]. Mix the acids in a capacious glass vessel, and, when effervescence has ceased, pour the product into dark, amber-colored, glass-stoppered bottles, which should not be more than half filled, and keep them in a cool place"—(U. S. P.).

Description.—"A golden-yellow, fuming, and very corrosive liquid, having a strong odor of chlorine. Completely volatilized by heat. It readily dissolves gold-leaf, and a drop ~~of~~ added to potassium iodide T.S., liberates iodine"—(U. S. P.). This mixture should be made in the open air to allow the disagreeable fumes to pass off. It should be kept in a dark-colored, glass-stoppered bottle, and the patient directed to keep it away from fires and light. On account of the property possessed by this mixture of dissolving platinum and gold—the noble metals—it was named "*aqua regia*" or "*royal water*." Heat causes it to lose its chlorine, while light may convert its chlorine into chlorhydric acid. It should not be made in great quantities on account of its proneness to decomposition if long kept in stock; nor should it be prepared extemporaneously, for sufficient time must elapse for the reaction to cease, and on no account must it be put in bottles and stoppered before effervescence has subsided. It contains free chlorine and several chlorinated products, among them *nitrosylchloride* (NOCl , chloronitrous acid), a yellow-red liquid, decomposed by water into nitrous and hydrochloric acids. Nitrosylchloride has a low boiling point— -5°C . (23°F .).

Action, Medical Uses, and Dosage.—Large quantities of this acid act as a corrosive poison like its constituents, and in poisoning by it like treatment should be instituted. Even small doses attack the dental enamel and gold fillings and produce gastric derangements. When used diluted as a bath, it is absorbed, increasing the hepatic and renal secretions, and producing a sense of burning in the mouth and fauces, and induces profuse pyalism, redness and tumefaction of the gums, and buccal ulcers. Diarrhoea is occasioned by it also. It was introduced as a remedy for *hepatic affections*, the bath being preferred, but it is not now much employed in this manner. Small doses of this or the diluted acid are sometimes employed in *hepatic calculi*, hepatic fulness and tenderness, *dyspepsia* with constipation or slight *jaundice*, *oxaluria*, *scrofula*, *sypilis*, and *skin diseases*, but it probably possesses no advantages over its constituents, and is more likely to disorder the stomach and bowels. Bathing with a dilute solution of this acid, say 1 part of acid to 6 of water, is asserted to have cured several cases of obstinate constipation. Some prefer the stronger to the diluted acid. A preparation which was once highly lauded for the cure of *corns*, *warts*, *cancers*, etc., Dr. Bleeker's remedy, is said to be a compound of nitrohydrochloric acid and cobalt. Dose of nitrohydrochloric acid, 1 to 5 drops, highly diluted, after meals, and followed by an alkaline wash to protect the teeth.

WHITE LIQUID PHYSIC.—A preparation has been highly recommended, called *White Liquid Physic*, or *Dow's Physic*. It is made as follows: Take sulphate of sodium $\frac{1}{2}$ pound, water $1\frac{1}{2}$ pints; dissolve, and then add nitrohydrochloric acid 2 fl $\frac{1}{2}$, powdered alum 68 grains. This preparation is used as a cooling purgative; also to allay nausea and vomiting—for *colic*, *hepatic diseases*, *oxaluria*, *diarrhoea*, etc. Given by some as a substitute for mercury. In *intermittent fever*, given in laxative doses, it has proved highly beneficial, especially when occurring in broken-down constitutions, and has cured the most obstinate cases of *dysentery*. Dose, 1 tablespoonful in a gill of water 3 times a day; or, in dysentery, given every hour, until it slightly operates the bowels, after which, every 3 or 4 hours. In order to protect the teeth from the action of the acid, in this preparation, each dose should be sucked through a straw, reed, or glass tube; and, immediately after the dose has been swallowed, the mouth should be rinsed once or twice with an alkaline solution. The above is the original recipe, and the addition of *sanguinaria*, etc., are uncalled for.

The White Liquid Physic as given by Dr. Scudder (*Mat. Med.*, p. 185), is made as follows: R Sulphate of sodium lb. ss; water Ojss; dissolve the sulphate of sodium in the water, and add nitric acid $\frac{3}{4}$ j; hydrochloric acid $\frac{3}{4}$ j. This he regarded as one of the most efficient remedies in *dysentery*, used to produce at least one bilious evacuation, and afterwards continued in smaller doses. "It acts directly upon the liver, removes the constipated state of the upper part of intestinal canal, lessens the tormina and tenesmus, and speedily checks the dysenteric discharge" (Scudder). Dose, a tablespoonful every hour in sweetened water until catharsis ensues.

ACIDUM NITROHYDROCHLORICUM DILUTUM (U. S. P.)—DILUTED NITROHYDROCHLORIC ACID.

SYNONYMS: *Diluted nitromuriatic acid, Acidum nitromuriaticum dilutum.*

Preparation.—"Nitric acid forty cubic centimeters (40 Cc.) [1 fl. 3, 169 m]; hydrochloric acid one hundred and eighty cubic centimeters (180 Cc.) [6 fl. 3, 42 m]; distilled water seven hundred and eighty cubic centimeters (780 Cc.) (26 fl. 3, 180 m). Mix the acids in a capacious glass vessel, and, when effervescence has ceased, add the distilled water. Keep the product in dark, amber-colored, glass-stoppered bottles, in a cool place"—(U. S. P.).

Description.—"A colorless, or pale-yellowish liquid, having a faint odor of chlorine, and a very acid taste. Completely volatilized by heat. From potassium iodide T.S. it liberates iodine"—(U. S. P.). In this product it is now accepted that the nitrosyl chloride of nitrohydrochloric acid is decomposed, through the presence of water, into hydrochloric acid and nitrogen trioxide, which forms a solution of nitrous acid. Like nitrohydrochloric acid, it contains free chlorine, thus necessitating that it be kept cool in a dark situation.

Medical Uses and Dosage.—Uses same as for nitrohydrochloric acid. Dose, 5 to 25 minims largely diluted with water, repeated 2 or 3 times a day, and followed by an alkaline wash to protect the teeth.

ACIDUM OLEICUM (U. S. P.)—OLEIC ACID.

FORMULA: $\text{HC}_{18}\text{H}_{35}\text{O}_2$. MOLECULAR WEIGHT: 281.38.

SYNONYM: *Elaic acid.*

"An organic acid, prepared in a sufficiently pure condition by cooling commercial oleic acid to about 5° C. (41° F.), then separating and preserving the liquid portion"—(U. S. P.).

Source and Preparation.—This acid was first obtained by Chevreul in 1821. It is a constituent of most fats, and of the non-drying fixed oils in the form of glycerin trioleate (triolein). It is obtained in large quantities as a by-product in the manufacture of candles. In this condition it is very impure, of a dark, reddish-yellow or brownish-red color (*red oil*), and at ordinary temperatures somewhat turbid. An early method of obtaining this acid was as follows: To procure *oleic acid*, treat oil of bitter almonds with caustic potash, and to the soap formed add hydrochloric acid; this separates the oleic and other acids. To the decomposed mixture add about half its weight of oxide of lead, and digest for 2 or 3 hours at a temperature of 100° C. (212° F.), by which means oleates of the fatty acids are formed. Ether is now added, which dissolves only the oleate of lead; the ethereal solution is mixed with an equal volume of water, to which hydrochloric acid is added as long as is required for decomposition, and the mixture is then well shaken. The ether rises to the surface, holding the oleic acid in solution; decant it and distill it off; there remains a compound of pure oleic acid with oxidized acid. By subjecting this compound to a temperature of about -7.2° C. (19° F.), the pure crystals of oleic acid form, while the oxidized acid remains in solution. Wolff recommends the substitution of petroleum benzin in the place of ether. The method of Chas. T. George (*A. J. P.*, 1881) is to dissolve dry, white castile soap (30 parts) in hot water (100 parts) and then to decompose the solution with sulphuric acid (6 parts). After washing the resulting oily layer with warm water, powdered litharge (2 parts) is added to it, and the lead oleate formed is dissolved, while warm, in petroleum benzin (10 parts). This solution is decomposed with weak hydrochloric acid (1 part with 12 of water). Evaporate the benzin, and oleic acid (15 parts) remains.

Description and Tests.—Oleic acid is a tasteless, inodorous, colorless, oily fluid at temperatures above 13.8° C. (57° F.), but when once melted it does not solidify until cooled to 4.4° C. (40° F.), and when solid it does not melt until heated to 13.8° C. (57° F.) It is not soluble in water, but readily soluble in alcohol or ether, floats on water, and becomes brown by the absorption of

atmospheric oxygen, with which it has a tendency to combine. It forms salts or soaps with bases. The oleic acid, as it occurs in non-drying fat oils, like olive oil, is chemically different from that occurring in drying oils, the type of which is linseed oil. Oleic acid, when in contact with nitrous acid, is converted into an isomeric solid compound called *elaidic acid*.

Oleic acid is not decomposed when distilled *in vacuo*, but if heated in the air it decomposes, forming hydrocarbons, *sebacic acid*, and volatile fatty acids. When treated with fused caustic potash, decomposition takes place, with acetic and palmitic acids as a result. With sodium and potassium hydroxides it forms soaps known respectively as *oleate of sodium* and *oleate of potassium*, classed among *hard* and *soft soaps*. This acid is used in the preparation of the *oleates*, a class of external applications now used in considerable quantities. The *United States Pharmacopœia* describes, as follows, the oleic acid that should be employed in pharmacy: "A yellowish or brownish-yellow, oily liquid, having a peculiar lard-like odor and taste; becoming darker and absorbing oxygen on exposure to air. Specific gravity about 0.900 at 15° C. (59° F.). Insoluble in water; soluble in alcohol, chloroform, benzol, benzin, oil of turpentine, and fixed and volatile oils. When cooled to about 4° C. (39.2° F.), oleic acid becomes semi-solid, and, on further cooling, congeals to a whitish, solid mass. When heated to a temperature of about 95° C. (203° F.), the acid begins to be decomposed, giving off acrid vapors. At a higher temperature it is completely dissipated. An alcoholic solution of oleic acid has a feebly acid reaction upon litmus paper. Equal volumes of oleic acid and alcohol, mixed at the ordinary temperature, should give a clear solution without separating any oily drops upon the surface (absence of fixed oils). If 1 Gm. of oleic acid be heated with 20 Cc. of alcohol, 2 drops of phenolphthalein T.S. added, and then a strong solution (1 in 4) of sodium hydrate, drop by drop, until the liquid has acquired a permanent red tint and the acid is saponified; next acetic acid added until the red color of the liquid is just discharged, and the liquid filtered—10 Cc. of the filtrate mixed with 10 Cc. of ether should not be rendered more than slightly turbid by the addition of 1 Cc. of lead acetate T.S. (absence of notable quantities of palmitic and stearic acids)"—(*U. S. P.*).

Linoleic acid is used to adulterate oleic acid. It may be detected with potassium permanganate, which converts oleic acid into *azaleinic acid*, and *linoleic acid* into *sativic acid*. The latter does not dissolve in ether while the former does. As little as 1 per cent of this impurity may be detected by this salt (*A. P. A. Proceed.*, 1890). Linoleic and ricinoleic acids constitute the fatty acids occurring in the drying oils.

Use.—Used only in preparing the *oleates*.

Related Products.—**SULPHO-OLEIC ACID.** *Sulpholeic acid* ($C_{17}H_{33}CO_2HSO_3H$). This acid is formed when sulphuric acid reacts upon castor, olive, almond, or other fixed oils, provided the temperature be not higher than 50° C. (122° F.). To obtain the acid in an anhydrous state ether is employed to remove the oil not acted upon, and the crude product is treated with alkaline carbonates or hydroxides, treated again with sulphuric acid, and finally evaporated in pure condition from benzin, or from ether. The substances known as *oleite*, *polysolve* and *solvine*, are neutral salts of this acid from its combination with alkaline bases. Water dissolves these salts (sulpholeates) and they in turn may be employed to render many otherwise insoluble substances miscible with water. *Sulphoricinoleic acid* is the name applied to that prepared with castor oil. The sulpholeates mix with many organic substances.

SULPHORICINIC ACID. Prepared by acting upon castor oil at a heat not higher than 50° C. (122° F.) with from 30 to 40 per cent sulphuric acid. Upon adding water, the sulphoricinic acid together with some free oil, separates as an oily stratum, an aqueous acid solution underlying. It is an active topical irritant. It, as well as its soluble salts are decided deodorizers and antiseptics. They have been used in ozena and like conditions. Salol sulphoricinate, creosote sulphoricinate, and naphthol sulphoricinate, have been employed as local medicines. *Phenolum natrio sulphoricinicum* is a yellowish liquid containing sodium sulphoricinate (80 per cent) and phenol (20 per cent). It is miscible in all proportions with water. A 20 per cent solution has been recommended as a topical application in *diphtheria*. *Skin and mucous-surface affections*, tubercular and otherwise, have been treated with it.

OLEITE (*Sodium sulphoricinoleate*) is a scarcely odorous, transparent, gelatinous fluid, soluble in water, alcohol, volatile oils, and chloroform. Its taste is acrid. It has extraordinary solvent powers upon many substances employed in medicine. It is non-poisonous internally or externally, and being soothing, is recommended as an ointment base. It is said to act kindly in *cuts, scalds, burns*, etc.

ACIDUM OXALICUM.—OXALIC ACID.

FORMULA: $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$. **MOLECULAR WEIGHT:** 125.7.

History.—Oxalic acid was discovered by Scheele, in 1776, and it is found in the organic as well as in the inorganic kingdoms. In plants it is generally met in combination with calcium or potassium; rhubarb, *Rumex acetosa*, *Oxalis acetosella*, *phytolacca*, *belladonna*, etc., contain the acid or bin-oxalate of potassium; rhubarb also contains oxalate of calcium, as likewise do many lichens, and in the human body it forms the mulberry calculus, a frequent form of gravel. In combination with calcium it is found in ginger, orris-root, squill, valerian, curcuma, quassia, and other drugs. As an ammonium oxalate it is present in the fertilizer *guano*. In the *Cicer arietinum* or *chick pea* it occurs in a free condition. It may also be formed artificially by the action of nitric acid on sugar, molasses, rice, starch, gum, wool, silk, hair, and many other organic compounds, which are free from nitrogen. Berthelot has obtained it synthetically from acetylene, ethylene, propylene, and allylene, by oxidation with permanganate of potassium.

Preparation.—There are several methods by which oxalic acid may be procured; the following are considered among the best:

1. Gently heat 1 part of pure starch with 8 parts of nitric acid of sp. gr. 1.200 or 1.250. A powerful reaction ensues, with an evolution of red nitrous acid vapors; when this diminishes, heat must be applied, and continued until no more red vapors are given off; if sufficiently evaporated, a large quantity of crystals of hydrated oxalic acid are deposited as the liquid cools. These are dried on a porous tile, then dissolved in a little hot water, and pure oxalic acid is deposited as the solution cools. The mother liquor remaining after the first deposit of crystals contains much free nitric acid, saccharic acid, and other products.

2. Digest 1 pint of sugar dried at 100°C . (212°F .) with 8.25 pints of nitric acid of sp. gr. 1.380. Evaporate the mixture to a sixth, and leave to crystallize. This process requires but an hour or two, and yields from 50 to 60 per cent of handsome crystals.

3. An ingenious and economical method of manufacturing oxalic acid from sawdust has been devised by Mr. Dale, of England. It is as follows: two equivalents of caustic soda and one equivalent of caustic potash are mixed together, dissolved in water, and the solution evaporated until it has a sp. gr. 1.350, when enough sawdust is to be stirred in to form a thick paste. This paste is heated on iron plates, being constantly stirred. At first, water escapes; the mass then swells; inflammable gases, hydrogen, and hydrocarbons are evolved, along with a peculiar aromatic odor. When the temperature has been maintained at 204.4°C . (400°F .) for an hour or two, this stage of the process is complete. The mass has a dark color, contains from 1 to 4 per cent of oxalic acid, and about 0.5 per cent of formic acid; the balance of the mass consists of an unknown substance, which is intermediate between cellulose and oxalic acid. The next stage consists in heating the mass till quite dry, being careful that no charring takes place; a gray powder is formed, containing from 28 to 30 per cent of oxalic acid, in combination with sodium and potassium. The gray powder is now washed on a filter with a solution of carbonate of sodium, which decomposes the oxalate of potassium, and converts it into oxalate of sodium, which is decomposed by boiling milk of lime, oxalate of calcium being precipitated while the sodium hydroxide remains in solution. The oxalate of calcium being placed in leaden vessels, is treated with sulphuric acid, which precipitates the calcium and leaves the oxalic acid in solution, which may be obtained in crystals by evaporation. The sodium hydroxide left in solution after the addition of milk of lime, may be recovered by boiling, and be again made use of with fresh sawdust. The same may be done with the potassium salt which filters through in the last stage. By this process 2 pounds of sawdust are made to yield 1 pound of oxalic acid.

Description.—Oxalic acid crystallizes in colorless, transparent, oblique, quadrilateral prisms with two-sided summits. The crystals are inodorous, have a strongly acid taste, faintly effloresce in a dry atmosphere, redden litmus paper, and when pure are completely volatilized by heat, and without becoming black-

ened. They dissolve in from 8 to 11 parts of water at 15.5° C. (60° F.), in their own weight of water at 100° C. (212° F.), and in 4 parts of alcohol; the addition of a small quantity of nitric acid to the water causes them to dissolve more readily. Nearly all the oxalates are insoluble in water, excepting the alkaline. Oxalate of calcium is insoluble, and hence oxalic acid is useful as a test for calcium, and is usually employed in the form of oxalate of ammonium; if the liquor to be examined contains any free acid, this must first be neutralized, as the oxalate can only detect calcium in neutral or alkaline fluids. Oxalic acid reduced by hydrogen is converted into glycolic and acetic acids, and if the action be kept up sufficiently long the glycolic becomes wholly formed into acetic acid.

Oxalic acid may be detected in any solution, by being entirely volatilized by heat; by yielding a white precipitate with nitrate of silver, soluble in nitric acid; and by giving a white precipitate with lime water, which is insoluble in water, readily soluble in nitric acid, insoluble in acetic acid, and which, when dried and heated to low redness, is converted, without blackening, into carbonate of calcium. Solution of sulphate of calcium produces a bluish-white precipitate with oxalic acid. Oxalic acid is sometimes contaminated with nitric acid, which gives a faint odor to it, and stains the cork of the bottle in which it is kept, yellow. If a very dilute solution of sulphate of indigo, containing the impure crystals, be boiled, the nitric acid present will decolorize the solution. On account of the resemblance between crystals of this acid and of magnesium sulphate, the latter has been used as an adulterant. This resemblance has also led to cases of poisoning, the person believing the acid to be Epsom salts. The acid may likewise be used for removing iron-rust and ink-stains from linen, and is employed in calico printing as a bleaching and discharge agent.

SALT OF SORREL, *Salt of lemon*, or *Essential salts of lemon* (acid or binoxalate of potassium), is well known to the laity as an agent to remove iron-stains, though oxalic acid is generally used now, and is often sold under these popular names.

Action and Toxicology.—Oxalic acid and the oxalates poison the nervous system and the blood, producing, as well, gastro-intestinal lesions. A dose of 60 grains killed a boy (Taylor). Again, by prompt treatment, two cases recovered after a half ounce had been swallowed. Death takes place in varying lengths of time, a circumstance that can not readily be accounted for. Some cases die in from 10 minutes to an hour. The above-mentioned boy died in 8 hours. The symptoms are an intensely pure, acid taste, burning of the parts over which the poison passes, intense pain, vomiting, especially a bloody material, an extremely feeble pulse, an inability to assume the upright posture, collapse, and stupor. These symptoms, with the rapidity with which death takes place, will point to oxalic acid as the cause. Still, persons have been known to live for 22 days, death being produced by a slow poisoning. The post-mortem changes are a whitened oesophago-gastric tract, though the stomach may contain a dark, gelatinous liquid, appearing like disorganized blood. The mucous coats are softened and loosened, but rarely perforated. The blood is excessively red, and in some instances oxalates have been found in the *tubuli uriniferi* of the kidneys. Koch regards it as a heart poison. The same lethal symptoms may be produced from salt of sorrel. Poisoning by oxalic acid, oxalate of ammonium, or oxalate of potassium, is best remedied by the speedy administration of chalk, suspended in water; when chalk can not be had, magnesia may be used; either of these forms insoluble oxalates.

Medical Uses and Dosage.—This article, unless in great attenuation, is an unfit agent for internal administration, though it has been given in doses of three-quarters of a grain every 3 hours in *diphtheria*. Such a procedure is certainly dangerous, and an infusion of sorrel, sumac-bobs, and similar substances containing the acid in combination, would even be hazardous. These infusions have, however, given excellent results in *diphtheria* and certain *sore throats* when used simply as a gargle. Webster (*Dynamical Therapeutics*, 175), praises the action of oxalic acid in lagging functions of the spinal cord due to over-exertion, thereby resulting in tense pains, marked lumbar weakness, and insomnia. One or two grains of the 6x trituration every 4 or 5 hours, are recommended in these conditions. A solution of oxalic acid in water promptly removes iron stains. For a number of years past I have used a saturated aqueous solution of it as an external

application in *cutaneous cancer, acne, scald head*, and several forms of cutaneous disease, since which, on my recommendation, others have employed it with success in similar affections, sometimes alone, and again with a small portion of creosote added. The saturated solution, neutralized by caustic potash, forms an excellent application to discuss *indolent tumors* (J. King).

ACIDUM PHOSPHORICUM (U. S. P.)—PHOSPHORIC ACID.

FORMULA: H_3PO_4 . MOLECULAR WEIGHT: 97.8.

ACIDUM PHOSPHORICUM (U. S. P.), *Phosphoric acid, Orthophosphoric acid.*

ACIDUM PHOSPHORICUM GLACIALE, *Glacial phosphoric acid*, $HPO_3=80$

ACIDUM PHOSPHORICUM DILUTUM (U. S. P.), *Diluted phosphoric acid.*

The official phosphoric acid should contain not less than 85 per cent of absolute orthophosphoric acid, and the diluted phosphoric acid 10 per cent, both by weight.

Source and Modifications.—When dry phosphorus is burned in the air or in the presence of dry oxygen, a white body, having the form of snow-like flakes, and the composition P_2O_5 , is produced. This is phosphoric anhydride (metaphosphoric anhydride, phosphorus pentoxide, or phosphoric oxide), and being very hygroscopic it unites with moisture with great avidity, becoming converted into a monobasic acid (HPO_3)—*glacial phosphoric acid* or *monobasic metaphosphoric acid*. A second modification of P_2O_5 is the commonly employed phosphoric acid or *normal or orthophosphoric acid* (H_3PO_4). Glacial phosphoric acid dissolved in water, and nitric acid added to the solution until red fumes cease to be evolved (U. S. P., 1870), will produce the orthophosphoric acid. The official acid is not now made in this manner, however, and, in fact, should not be so prepared on account of the impurities in commercial glacial phosphoric acid, but is produced from bone ash, which is principally a tricalcium phosphate (a salt of tribasic orthophosphoric acid). A third modification is that produced by carefully heating crystallized orthophosphoric acid to a temperature of $213^\circ C.$ ($415.4^\circ F.$), when 1 molecule of water is expelled from 2 molecules of the acid, thus: $2H_3PO_4 - H_2O = H_4P_2O_7$. This product is *pyrophosphoric acid* (the bibasic diphosphoric acid). It is a sour, colorless, inodorless acid, and gives rise to the pyrophosphates.

Preparation.—I. ACIDUM PHOSPHORICUM, *Phosphoric acid*.—C. L. Diehl, Jr., recommends the following modification of the London process as a perfectly safe one: Into a French glass tubulated retort of 42 parts capacity introduce 12 parts of distilled water and 2 parts of phosphorus. Place the retort on a sand-bath and introduce through a funnel tube, fixed in the tubulure by means of a cork and reaching half an inch below the level of the liquid, 8 parts of nitric acid. Apply gentle heat, and watch the operation closely as soon as reaction commences. When the reaction slackens, add more nitric acid in portions of about one-fourth at a time. Should the reaction become violent, small quantities of warm water must be added until it is reduced to its ordinary action, which may be compared to the gentle boiling of water. The formation of frothy bubbles on the surface of the liquid is always the forerunner of violent reaction, and should be checked at once. I have found that if checked at this stage, a comparatively small amount of water would answer, but if allowed to react violently a much larger quantity of water will be required. After the phosphorus is all oxidized evaporate the acid in a porcelain capsule. As owing to the rapid disengagement of nitric oxide the liquid will froth up toward the termination of the process of evaporation, the capsule should have about three times the capacity of the acid when concentrated, and a little distilled water should be kept conveniently near, to add in case there is danger of frothing over. The operation should be conducted under a good furnace-hood, or else the beak of the retort should be introduced into a good flue, to carry off the vapors—*Amer. Jour. Pharm.*, 1867, p. 138).

II. ACIDUM PHOSPHORICUM GLACIALE, *Glacial phosphoric acid*.—Sulphuric acid and white-burned bones, of each, 1 part; water, 15 parts. Add the water to the acid and the bones to the solution, and digest until a smooth white paste of calcium sulphate is produced from the insoluble portion of the bones. Filter and wash with water; and to the filtrate, which contains phosphoric and sulphuric

acids and solution of phosphates of calcium and magnesium, add aqua ammoniæ or ammonium carbonate to neutralization. Finally, filter again to separate the precipitate of phosphates and evaporate. Completely drive off the ammonia from the phosphate of ammonium by heating the latter in a platinum crucible. Pour the melted acid on smooth iron surfaces, cool, and transfer the glassy masses to closely-stoppered bottles.

This acid may also be obtained by heating mono-sodium phosphate to redness, which expels one molecule of water; the fused mass is then dissolved in water, and precipitated by acetate of lead. The lead precipitate is treated with sulphide of hydrogen, which decomposes the lead salt, forming a sulphide of lead, and leaving the acid free in the solution. Its dilute solution may be kept without change, but boiling converts it into ordinary phosphoric acid. The chemistry of the modifications of phosphoric acid was first definitely established by Thomas Graham in 1833. Ordinary phosphoric acid was discovered in tri-calcium phosphate by Gahn in 1769, but was not isolated until Scheele obtained it in 1771.

The solutions of the foregoing modifications present the following differences in reaction :

	With albumen.	With calcium chloride.	With barium chloride.	With argentic nitrate
METAPHOSPHORIC ACID, HPO_3, ($\text{H}_2\text{P}_2\text{O}_7$, Rother).	Coagulation	White precipitate.	White precipitate.	Gelatinous, transparent precipitate.
ORTHOPHOSPHORIC ACID, H_3PO_4, ($\text{H}_4\text{P}_2\text{O}_7$, Rother).	No effect...	No effect...	No effect...	Yellow precipitate if a small amount of aqua ammoniæ be added. No precipitate with silver nitrate alone.
PYROPHOSPHORIC ACID, $\text{H}_4\text{P}_2\text{O}_7$.	No effect...	No effect...	No effect...	White precipitate if a small amount of aqua ammoniæ be added. Its solution yields a precipitate with silver nitrate alone, which is insoluble in excess of the acid.

It will be observed that the three acids—metaphosphoric, pyrophosphoric, and orthophosphoric—are chemical combinations of phosphoric oxide (P_2O_5), with one, two, and three molecules of water respectively, thus:

III. ACIDUM PHOSPHORICUM DILUTUM (U. S. P.), Diluted phosphoric acid.—Take "phosphoric acid, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; distilled water, seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]. To make eight hundred and fifty grammes (850 Gm.) [1 lb. av., 13 ozs., 430 grs.]. Mix them. Keep the product in well-stoppered bottles"—(U. S. P.).

Description.—**I. ACIDUM PHOSPHORICUM (U. S. P.), Phosphoric acid.**—"A liquid composed of not less than 85 per cent, by weight, of absolute orthophosphoric acid [$\text{H}_3\text{PO}_4=97.8$], and not more than 15 per cent of water. The above-mentioned percentage (85) is that assumed for phosphoric acid in the formulas of pharmacopœial preparations. Phosphoric acid should be kept in glass-stoppered bottles"—(U. S. P.). The Pharmacopœia directs: "A colorless liquid, without odor, but having a strongly acid taste. Specific gravity, not below 1.710 at 15° C. (59° F.). Miscible, in all proportions, with water or alcohol. When heated the liquid loses water; at 200° C. (392° F.) it gradually begins to change to pyrophosphoric acid. At a still higher temperature it is converted into metaphosphoric acid, which volatilizes in dense fumes, or forms, on cooling, a transparent mass of glacial phosphoric acid. The acid, even when largely diluted, has an intensely

acid reaction upon litmus paper"—(*U. S. P.*). Although evaporated so as to become dense, this acid does not act upon animal and vegetable matter like sulphuric and other mineral acids.

II. *ACIDUM PHOSPHORICUM DILUTUM (U. S. P.)*, *Diluted phosphoric acid*.—"Diluted phosphoric acid contains 10 per cent, by weight, of absolute orthophosphoric acid. Specific gravity, about 1.057 at 15° C. (59° F.). It corresponds in properties to phosphoric acid (see *Acidum Phosphoricum*), and should conform to the same reactions and tests. 4.89 Gm. of diluted phosphoric acid should require for neutralization 10 Cc. of normal potassium hydrate V.S. (each cubic centimeter corresponding to 1 per cent of the absolute acid), phenolphthalein being used as indicator"—(*U. S. P.*).

Microscopic vegetative growths may spring up in diluted phosphoric acid if the preparation be kept for too great a length of time. This change may be prevented by the presence of a mere trace of chlorhydric acid.

III. *ACIDUM PHOSPHORICUM GLACIALE*, *Glacial phosphoric acid*.—Pure glacial phosphoric acid is a soft mass, somewhat gummy in consistence, and requires the presence of some alkaline base, as sodium, to render it solid and glassy when cold. It requires a high temperature to fuse it, and volatilizes at a red heat. The commercial glacial phosphoric acid does not correspond to the former in its properties, and is apt to be a very impure product, large quantities of sodium phosphate and other salts having been found in samples of it. It is chiefly made in Germany. The acid of commerce is in reality a mixture of metaphosphoric and pyrophosphoric acids, the proportion varying according to the manner of making it, whether the heating has been prolonged or not, or whether or not too high a temperature is maintained. The commercial product occurs in glass-like masses, transparent and deliquescent, and its solution in both water and alcohol has an acid reaction and is strongly acid to the taste. Its aqueous solution gradually changes to ordinary phosphoric acid, a change which is accelerated by boiling, or by the presence of nitric acid. The time required for this conversion of a solution of 1 part acid to 2 parts of water is about 15 minutes (L. Thompson).

Tests.—The *Pharmacopœia of the United States* directs the following tests: "If a small portion of phosphoric acid be supersaturated with ammonia water, the addition of magnesium sulphate T.S. (or of magnesia mixture) produces a white, crystalline precipitate. If this precipitate be dissolved in diluted acetic acid, the solution yields a yellow precipitate with silver nitrate T.S. If a crystal of ferrous sulphate be dropped into a cooled mixture of 1 Cc. each of phosphoric and sulphuric acids, no brown or brownish-black color should appear around the crystal (absence of nitric acid). If 1 Cc. of phosphoric acid be diluted with 5 Cc. of water, and the liquid gently warmed, it should not be blackened upon the addition of a small amount of silver nitrate T.S., or rendered turbid by mercuric chloride T.S. (absence of phosphorous acid). If 1 Cc. of phosphoric acid (in which nitric and phosphorous acids have previously been shown to be absent) be mixed with 1 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), and a small piece of pure tin-foil added, no coloration should appear within 1 hour (limit of arsenic). Upon adding to 1 Cc. of phosphoric acid a mixture of 3 Cc. of alcohol and 1 Cc. of ether, no turbidity should appear (absence of phosphate). After neutralizing a portion of the acid with ammonia water, the addition of ammonium sulphide T.S. should produce neither a color nor a precipitate (absence of iron, etc.). After diluting a portion of the acid with 5 volumes of water, no precipitate should be produced, in separate portions of the liquid, by barium chloride T.S. (absence of sulphuric acid), or by silver nitrate T.S. (absence of hydrochloric acid); nor should any precipitate be formed, even after several hours, by the addition of an equal volume of tincture of ferric chloride (absence of pyrophosphoric and metaphosphoric acids). 0.978 Gm. of phosphoric acid, diluted with water, should require, for neutralization, not less than 17 Cc. of normal potassium hydrate V.S. (each cubic centimeter corresponding to 5 per cent of the absolute acid), phenolphthalein being used as indicator"—(*U. S. P.*). Another important test for phosphoric acid is that of molybdate of ammonium, made by dissolving molybdic acid in excess of ammonia, detecting even traces of it; when added in excess, it forms with this acid a bright yellow precipitate of ammonium phospho-molybdate of the composition

$2\text{PO}_4(\text{NH}_4)_3 + 22\text{MoO}_3 + 12\text{H}_2\text{O}$ (Rammelsberg). However, the composition seems to vary according to conditions. If diluted phosphoric acid be neutralized with ammonia, nitrate of silver occasions a yellow precipitate of phosphate of silver. Arsenous acid is the only acid similarly acted on; and it may be determined from phosphoric acid by the action of hydrogen sulphide, which causes a yellow precipitate with the arsenous acid, while it has no effect at all upon the phosphoric. Arsenic may also be detected by Marsh's test.

Action, Medical Uses, and Dosage.—This acid produces the usual effects of the diluted mineral acids, but is milder and more assimilable. In addition, a mild intoxication, not unlike that produced by alcohol, is produced by doses ranging from 40 to 180 minims. Larger doses produce a feeling of inertia and drowsiness, which persists for some little time. Locally, when concentrated, it is irritant and mildly escharotic. By improving the appetite and digestion, it favors nutrition and growth. It has been used to check *abnormal osseous secretions*, to remove *phosphatic urine*, to relieve *spasmodic affections*, and is frequently beneficial in the *nervous debility* of persons advanced in years, in the thirst accompanying *diabetes*, in *impotency*, or feebleness of the sexual functions, and in *fluor albus*. That form of *diabetes* induced by mental disturbances, and in broken-down, nervous individuals, is the kind benefited by it. *Functional deafness*, from inner ear disorders with atony of the nervous system, is specially met by drop doses of the diluted acid every 3 hours. In *eye disorders*, with involvement of the deeper tissues with atony, it is a pronounced remedy. The indication is *atony* of the eye and its appendages. It is indicated in nervous atony of the lid and ocular muscles, tobacco or alcoholic *amblyopia* (with nux if indicated), and in the *keratitis* of enfeebled persons. *Disseminated choroiditis* has been cured by it (Foltz). Externally it has been advantageously applied to *indolent ulcers*. From 1 to 30 drops may be given for a dose, mixed with an ounce or two of water, and this may be repeated 2 or 3 times a day.

Specific Indications and Uses.—Thirst; nervous and mental derangements; insomnia with atony; atonic nervous troubles of the eye and ear; functional deafness with debility.

Related Acid.—ACIDUM METAPHOSPHORICUM DILUTUM (N. F.). *Diluted metaphosphoric acid, Acidum phosphoricum glaciale dilutum, Diluted glacial phosphoric acid.* *Formulary number, 7:* "Glacial phosphoric acid one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; distilled water (enough to make one thousand cubic centimeters) (1000 Cc.) [33 fl. 3, 391 m.]. Dissolve the acid in the water without heat.

"This preparation should be kept in a cool and dark place, and should not be prepared in larger quantity than may be consumed within a few months.

Note.—The resulting product contains about 10 per cent of metaphosphoric acid, provided the glacial acid was free from impurities. That which is sold in form of glassy lumps is usually of sufficient purity. The variety in form of round sticks is more or less impure, containing generally more than 15 per cent of phosphate of sodium. If this variety is alone available, a proportionately larger quantity must be taken, to be determined, if time permits, by an assay of the free acid present. If no special accuracy is required, about 115 Gm. [4 ozs. av., 180 grs.] of this variety of the acid may be reckoned to be equivalent to the quantity directed in the above-given formula.

"Whenever pyrophosphate of iron (U. S. P.) forms one of the ingredients of a mixture containing diluted phosphoric acid, the official tribasic acid is unsuitable, as it produces with the salt a gelatinous precipitate. If a clear mixture is required the above preparation is to be used in place of the official. The same may be done when phosphate of iron (U. S. P.) is prescribed, though the precipitate caused by the official acid in this case is not as bulky, and under certain conditions may not form at all"—(Nat. Form.).

ACIDUM PICRICUM.—PICRIC ACID.

FORMULA: $\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$. **MOLECULAR WEIGHT:** 228.57.

SYNONYMS: *Carbazotic acid, Nitrophenic acid, Nitrophenolic acid, Nitropicric acid, Trinitrophenic acid, Trinitrophenol, Weller's bitter.*

Source and Preparation.—Picric acid is the product of the action of strong nitric acid on indigo, gum benzoin, coumarin, aloes, Australian gum, salicin, oil of gaultheria, phloridzin, silk, wool, leather, and other complex, organic substances, aided by heat, but is principally prepared from carbolic acid by the action of either nitric acid, followed by fuming nitric acid, or sulphuric acid and Chili saltpetre

(nitrate of sodium). It is principally prepared from phenol, and the following formula is in frequent use: Take carbolic acid, 1 part; nitric acid, 3 parts; fuming nitric acid, 3 parts; warm the nitric acid and add the carbolic acid, drop by drop. This produces a violent reaction. After the violence of the reaction has abated, add the fuming nitric acid, heat, and evaporate the mixture, when picric acid will crystallize on cooling. Wash the product with cold water, and recrystallize with hot water or diluted alcohol.

An old formula, showing the preparation of picric acid from indigo, is as follows: Reduce the best indigo to a coarse powder, and digest it with ten times its weight of hot nitric acid, of specific gravity 1.430, added in small portions at a time. It dissolves with a copious emission of nitrous fumes, while it froths up very considerably. After the violent ebullition is over, raise it to the boiling temperature. Then add a little more concentrated nitric acid, continuing it, from time to time, as long as red fumes are disengaged. When the liquid has cooled there will be deposited a great quantity of yellow-colored, semi-transparent crystals; and if the process was properly conducted, neither resin nor artificial tannic acid makes its appearance. Wash these crystals in cold water and dissolve them in boiling water, and crystallize a second time. To obtain the picric acid quite pure, dissolve these crystals again in boiling water, and saturate them with carbonate of potassium; on cooling, crystals of picrate of potassium form. It is best to dissolve and crystallize them two or three times. When this salt is sufficiently pure, dissolve it in water and decompose it by nitric, hydrochloric, or sulphuric acid. When the solution cools, picric acid is deposited in beautiful crystalline plates. More of the acid may be obtained from the mother-liquors by a similar process. 4 parts of indigo yield about 1 part of picric acid. Great care is necessary to obtain it free from indigotic and oxalic acids.

Description.—Picric acid forms long, brilliant, whitish-yellow prisms with rectangular bases, which, in thin layers, are almost colorless. It reddens vegetable blues, and has an exceedingly bitter taste; it is fusible and volatile, and burns with a yellow flame, leaving a residue of charcoal. It is nearly insoluble in cold water, but soluble in hot water, alcohol, ether, benzol, chloroform, and petroleum benzin. It is not acted upon by chlorine, iodine, hydrochloric acid, nitro-hydrochloric acid, or cold sulphuric acid. Concentrated sulphuric or nitric acids dissolve it unaltered, and deposit it on the addition of water. Heated in an amount of water insufficient to dissolve it, the acid melts to a yellowish, transparent oil, which solidifies on cooling. Heated alone, the acid fuses to a yellowish oil; if the temperature be gradually raised, it may be partially sublimed; suddenly heated, it decomposes with explosion. It colors the skin, hair, and especially animal membranes, permanently yellow. It forms salts with bases, called picrates (carbazotates), which also detonate in high temperatures. Gelatin is precipitated by its solution in water. Its alcoholic solution is a good reagent for detecting the presence of potassium in sodium salts; the picrate of potassium is sparingly soluble, and is deposited in minute yellow crystals, while the picrate of sodium is very soluble. It will stain wood, and is much used by dyers to impart a permanent yellow color to silk and woollen goods. If it be used with indigo, various tints of green may be obtained. Picric acid and its ammonium salt are now extensively used in the production of "smokeless gun-powder." A saturated solution will show the presence of albumen in urine. Into a test-tube containing the solution, drop the urine, and if it contains albumen, at the point of junction of the two liquids a white line will be observed (Gallippe, *Ed. Med. Jour.*, 1873). More recently the picric acid test for albumen was modified by the additional use of citric acid (Esbach's solution, containing 2 per cent of citric and 1 per cent of picric acid). In the practice of medicine the name carbazotic acid is still in favor.

The aqueous solution, 1 to 100, is used as a laboratory test for alkaloids, most of which, excepting morphine, cocaine, coniine, caffeine, hyoscyamine, aconitine, and theobromine, will be thrown down from weak acidulous solutions.

Action and Medical Uses.—Picric acid and the picrates (carbazotates) impart a yellow coloration to the skin of man, and to the urine and conjunctiva in both man and animals. Diarrhoea, intestinal sanguineous extravasation, flatulent accumulations, depression, loss of flesh and muscular twitchings were observed in a rabbit.

This acid was formerly much used both internally and externally in various disorders, chiefly in *intermittents*, and *intestinal worms*. Picric (carbazoic) acid is tonic and astringent, the latter influence being effected by improving the general tone of the system. It has been efficaciously used in convalescence from acute diseases, *cephalgia*, *chronic diarrhoea*, *gastric irritability*, *dyspepsia*, *anemia*, and *intermittent fever*; in which last disease it was once considered a valuable substitute for quinine, and is especially efficacious in those cases of *ague* in which, from continuous use, quinine has lost its effect. As the free acid is apt to occasion cramps in the stomach, the picrates of ammonium and iron have been found preferable. The picrate of ammonium and gallic acid, 1 grain each, with one-sixth of a grain of opium for a dose, may be repeated 3 times a day, in obstinate *diarrhoea*. By the use of these agents the skin and conjunctiva become temporarily colored, so as to closely resemble jaundice, and would deceive the keenest observer; the acid has been detected in the urine, even when this has been kept several days. Its intensely bitter taste is a bar to its use. The dose of the acid and its salts is from half a grain to a grain, repeated 3 times a day—(Moffatt, Crace Calvert). Webster suggests its possible curative action in *pernicious anemia* and *leukemia*, in 2 or 3 grain doses of the 3x or 6x triturations every 4 hours. It is now chiefly used as a laboratory reagent. An alcoholic solution may be applied to *burns*.

ACIDUM SALICYLICUM (U. S. P.)—SALICYLIC ACID.

FORMULA: $\text{HC}_6\text{H}_5\text{O}_3$. MOLECULAR WEIGHT: 137.67.

SYNONYMS: *Oxybenzoic acid*, *Ortho-oxybenzoic acid*.

"An organic acid, existing naturally, in combination, in various plants, but most largely prepared synthetically from carbolic acid"—(U. S. P.).

Source and History.—In the year 1839, an article, from the pen of M. Piria, stated that by heating salicin, with mixtures of bichromate of potassium and sulphuric acid, an oily product was obtained, which he named *hydruret of salicyl* (since known as salicylous acid). When this substance was heated with caustic potash, the mass dissolved in water, and then treated with excess of hydrochloric acid, a white substance crystallized, which Piria named *salicylic acid*. Soon afterward, Cahours and Gerhard obtained it, by decomposing wintergreen oil. Kolbe and Lautemann (*Ann. de Chim. et Pharm.*, cxiii.) succeeded in preparing salicylic acid, by passing carbonic acid gas through carbolic acid, at the same time adding fragments of metallic sodium. The residuum was dissolved in water and an excess of hydrochloric acid added, when impure salicylic acid separated. Afterward, Kolbe found that by preparing dry carbolate of sodium, and heating it to the temperature of 100°C . (212°F .), gradually increased to 220°C . (428°F .) [not to exceed 250°C . (482°F .)], while at the same time a constant stream of carbonic acid gas is kept passing through the retort, phenol will distill over, and disodium salicylate remain in the retort, thus: $2(\text{C}_6\text{H}_5\text{ONa}) + \text{CO}_2 = \text{C}_6\text{H}_5\text{ONa} \cdot \text{CO}_2\text{Na} + \text{C}_6\text{H}_5\text{OH}$.

This preparation was very impure, however, and it was not until after the year 1875 that, from this source, white salicylic acid became an article of commerce. Rautert (1875) found that pure salicylic acid would distill with a current of steam, thus enabling chemists to easily purify Kolbe's dark-colored or yellow preparation; and Dr. Squibb recommends this process in practice. At present, the bulk of salicylic acid found in commerce is prepared from carbolic acid. The following process, devised by R. Schmitt, was patented in 1885. Phenol-sodium is acted upon by a current of carbon dioxide (CO_2) at ordinary temperature, resulting in the formation of sodium phenyl carbonate as follows: $\text{C}_6\text{H}_5\text{ONa} + \text{CO}_2 = \text{C}_6\text{H}_5\text{O} \cdot \text{COONa}$. This substance is then heated in closed vessels to a temperature of 120°C . to 140°C . (248°F . to 284°F .), an intramolecular change taking place, whereby monosodium salicylate ($\text{C}_6\text{H}_4(\text{OH}) \cdot \text{COONa}$) is produced; from this salt salicylic acid is easily liberated by hydrochloric acid. Salicylic acid is likewise found in the leaves of wintergreen (*Gaultheria procumbens*), and in allied plants, as methyl-salicylate ($\text{C}_6\text{H}_4(\text{OH}) \cdot \text{COCH}_3$). Cahours and Gerhard discovered it in the former about 1843. Cahours also obtained it while fusing a mixture of indigo and hydrate of potassium at high temperature; and Delandès, by a

somewhat similar action, upon coumarin. Distilled oil of meadow sweet (*Spiraea ulmaria*) readily yields it, as this oil is, mainly, salicylous acid ($C_7H_5O_2$). Prof. E. S. Wayne obtained salicylic acid, from an oil, distilled from buchu leaves, and Prof. J. U. Lloyd (1877) from an oil, obtained by distillation from senega root. [This oil proved to be identical, in character, with oil of wintergreen]. Mandelin (1881) proved its existence in several species of violets.

Preparation.—To prepare salicylic acid, dissolve, in an evaporating dish, 24 parts of white hydrate of potassium, by means of a similar amount of distilled water, and raise the temperature of the solution to $82.2^\circ C.$ ($180^\circ F.$); then add, with constant stirring, 8 parts of oil of wintergreen (*Gaultheria procumbens*). When effervescence ceases, pour the solution into a mixture, composed of hydrochloric acid, 4 parts, and distilled water 10 parts; stir well, and allow the mixture to remain in a cool place for 24 hours; then pour it upon a muslin strainer, drain the crystalline magma, redissolve it in boiling water, and crystallize by cooling; or, dissolve the precipitate in alcohol, and then reprecipitate, by the addition of water. Pure wintergreen oil must be employed in this process, because, if adulterated with sassafras oil, as is often the case, much trouble will be experienced in purifying the acid.

Description and Tests.—Salicylic acid separates from concentrated solutions, when rapidly cooled, in the form of small, crystalline tufts of minute acicular crystals. It is inodorous, but the crude salicylic acid in course of preparation, from wintergreen oil, possesses, from the presence of foreign matters, the peculiar odor of fresh willow bark, an odor familiar to those who have visited willow plantations, and have become impressed with the exhalation from freshly-stripped willows. When pure, this acid imparts, at first, a sweetish taste, which quickly becomes acid and disagreeable. It sublimes, when gradually heated, but, according to Biel, after sublimation it has a tendency to spontaneously decompose into carbolic acid and carbonic acid gas. It unites with alkalis to form salts, the sodium salicylate being considerably employed in medicine. The dust of salicylic acid is irritating, if inhaled, exciting coughing and a sense of suffocation. In making solutions of salicylic acid in water, phosphates or acetates of the alkalis are often added, as salicylic acid is very soluble in these solutions. It is stated that a compound of borax with salicylic acid, $Na(B.OH)2C_7H_5O_2$, may be formed, and in practice, it is customary for physicians to add borax when desiring to make an aqueous solution of the acid. This solution soon acquires a bitter, unpleasant taste. The official acid is thus described: "Light, fine, white, prismatic needles, or a light, white, crystalline powder; odorless, having a sweetish, afterward acrid taste, and permanent in the air. Soluble at $15^\circ C.$ ($59^\circ F.$), in about 450 parts of water, and in 2.4 parts of alcohol; in 14 parts of boiling water, and very soluble in boiling alcohol. Also soluble in 2 parts of ether, 2 parts of absolute alcohol, and 80 parts of chloroform. When heated to $156^\circ C.$ ($312.8^\circ F.$), the acid begins to melt, and is completely melted at $157^\circ C.$ ($314.6^\circ F.$); at a higher temperature it is gradually dissipated without leaving more than 0.6 per cent of fixed residue. The saturated aqueous solution has an acid reaction, and is colored intensely bluish-violet (in high dilution violet-red) by ferric chloride T.S."—(*U. S. P.*).

CRESOTIC ACID, $C_8H_7O_2$,—is a homologue of salicylic acid, and the properties of commercial salicylic acid are said to be often considerably modified by its presence. It is more soluble in boiling water, but likewise, produces the violet reaction with ferric chloride. This impurity, as well as phenol, is liable to be found only in salicylic acid artificially prepared from carbolic acid. That made from wintergreen oil may contain chloride of potassium, recognized by remaining insoluble, when the acid is washed with excess of alcohol. For medicinal use, the acid from wintergreen is often preferred by physicians.

"On adding to a small portion of salicylic acid, in a test-tube, about 1 Cc. of concentrated sulphuric acid, then, cautiously, about 1 Cc. of methylic alcohol, in drops, and heating the mixture to boiling, the odor of methyl salicylate will be evolved. On allowing a saturated alcoholic solution of the acid to evaporate spontaneously in a glass or porcelain capsule, in a place protected from dust, a perfectly white, crystalline residue should remain (absence of iron, carbolic acid, or coloring matter). If 1 Gm. of the acid be dissolved in an excess of cold

sodium carbonate T.S., the liquid agitated with an equal volume of ether, and the ethereal solution allowed to evaporate spontaneously, the residue, if any, should be free from the odor of carbolic acid. On treating about 0.5 Gm. of the acid, in a clean test-tube, with 10 Cc. of concentrated sulphuric acid, no color should be imparted to the latter within 15 minutes (absence of readily carbonizable, organic impurities). A solution of 0.5 Gm. of the acid in 10 Cc. of alcohol, mixed with a few drops of nitric acid, should remain unaffected upon the addition of a few drops of silver nitrate T.S. (absence of hydrochloric acid)"—(*U. S. P.*).

Action.—According to MM. Chirone and Petrucci, animals subjected to the daily ingestion of this acid, rapidly emaciate, and lose much of their weight. With frogs and mammals, it always diminishes the number of pulsations; in large doses it elevates the temperature of the body, and diminishes the number of respirations; in small doses it lowers the temperature. According to others, its use is apt to occasion more or less deafness, tinnitus, pain in the forehead, manual tremors, and accelerated respiration; and very large doses induce intense cephalalgia, tremors, excessive debility, hurried respiration, some lesion of the kidneys, and tingling sensations in the extremities, and, in some instances, rapid collapse, and cerebral symptoms, varying from those resembling cinchonism to nearly acute delirium. Sudden temporary amaurosis (Gatti) with recovery in 10 hours, occurred in an individual to whom 125 grains of sodium salicylate had been administered. Dimness of vision, ptosis, and strabismus are not uncommon results from its use. H. Kohler states that it depresses the respiratory activity, and may even occasion death by asphyxia. Auger observes that its prolonged use in large doses, especially with women, is very apt to occasion nausea, vomiting, pyrosis, diarrhoea, angina, tinnitus, and even deafness, redness of the face, and slight congestion; and that, with inebriates, it may determine a furious delirium. These results, he adds, may sometimes be prevented or mitigated, by administering it in milk, or in unleavened bread with a cup of milk. Pye Smith has observed that the urine of a patient who had been taking salicylic acid, gave the characteristic saccharine reaction, with the copper test; while Muller and others have found its sodium salt to temporarily, or permanently, as the case may be, cause the diabetic sugar to completely disappear. M. Gubler observes, that when the kidneys are normal the use of salicylic acid occasions diuresis, while, on the contrary, the urine is in diminished amount and even albumen is present in, more or less, considerable quantity, when there is a lesion of these organs. Salicylic acid imparts to the urine a characteristic olive-green tint. M. Bucquoy cites a case in which abortion, at the sixth month, followed the administration of this acid; and he also inquires whether the rapid deaths of certain patients, treated with this acid, and especially when the doses were large, may not be due to uremia, occasioned by its use. One or two writers have stated that the osseous system is affected by its use, and we are aware of several instances in which caries of the teeth occurred after a treatment with salicylic acid; but whether due to this acid is a question yet to be determined. Many of the serious symptoms following its employment have been attributed to an impure preparation; yet as such symptoms have been observed, it behooves the medical practitioner, not only to be certain that he is employing the pure acid, but, likewise, to be careful in its administration, and to closely watch its effects, that he may be the better prepared to promptly remove any undesirable symptoms that may arise therefrom. The irritating action of this acid, upon the mucous membrane of the mouth, pharynx, œsophagus, etc., is said to be due to impurities; but the pure acid will occasion a dryness of the mucous membrane, followed by slight burning and increased saliva.

If a solution of salicylic acid be sprayed upon plants they quickly die. Added to milk and beer it prevents organic changes by checking the fermentative processes. If added to urine it will stop all putrefactive processes, and if it be ammoniacal, it will be promptly deodorized. Fermentation of urine within the bladder may be checked by the internal administration, or by injection, of solutions of this acid or one of its alkaline salts.

Medical Uses and Dosage.—The therapeutical virtues of salicylic acid are not satisfactorily determined; while many physicians highly extol it, as possessing certain valuable properties, as many others, on the other hand, emphatically

deny this, and attribute the results following its employment to other causes. By various investigators, it has been claimed that salicylic acid is an antiseptic and germicide; by others, that it is a disinfectant, a deodorizer, an astringent, and an antipyretic. Kohler and some others consider it an antiseptic and germicide only when locally applied, because when taken internally it becomes united with an alkali, loses its antiseptic action, and produces effects similar to those following the ingestion of sodium salicylate. MM. See, Laborde, and others, state that the good effects following its internal administration are entirely due to its action as an analgesiant, and deny that it has any antiseptic, antipyretic, or antiperiodic action, when thus employed. Prideaux speaks highly of its efficiency in *smallpox*, when in combination with ammonium and sodium salts; his formula is a mixture of carbonate of ammonium, carbonate of sodium, each 5 grains, salicylic acid 20 grains, water 1 fluid ounce; the dose is one-half, or the whole, of this solution, given every 4 or 6 hours. It is pleasant to the taste, unirritating to the intestinal canal, and modifies the disease so as to arrest it in its second and third stages, and also to prevent pitting, after recovery, in consequence of the absence of pus formation (*Braithwaite's Retrospect*, January, 1878, p. 188, from *Med. Exam.*). Letzerich states that upon the addition of salicylic acid to the diphtheritic organisms in the urine of children affected with severe *diphtheria*, and which consisted of bacteria, micrococci, and protoplasmic masses, the bacteria were destroyed, and the corpuscles of the plasmic substance became dim, presented a double margin, and apparently contained air-bubbles. He considers it a powerful anti-diphtheritic agent, and has successfully treated several cases of the disease, using a solution of the acid as a gargle, and applying the pulverized acid over the affected surface. Others, again, have derived no benefit whatever from its employment in diphtheria. But it is useless to continue these discordant statements, from which it will readily be seen that even its acknowledged partisans are not agreed as to its therapeutical virtues, and that our knowledge concerning its value is still very imperfect; and until more satisfactory information concerning its action shall be had, it will be advisable to employ it with great care and prudence, to closely watch its effects, and to at once suspend its administration whenever any unexpected symptoms appear, or when any doubt exists as to its influences upon the system, or any of its organs. Salicylic acid, and its salts, appear in the urine, partly free, partly in the form of salicyluric acid, in from 20 to 30 minutes after its ingestion, and may be known by the violet color produced when a solution of ferric chloride has been added to this fluid; also, by its deviating to the left the plane of polarization, from the presence of salicin.

Salicylic acid, as well as its salts, as salicylate of sodium, of calcium, of lithium, of ammonium, of quinine, have undoubtedly been found of great value in *acute articular rheumatism*, rapidly reducing the temperature and the pulsations, and mitigating the pain, thus tending to prevent serious complications, allowing the excretory organs to eliminate any noxious substance, and lessening the intensity and duration of the disease. As with all remedies, failures may occur, chiefly owing to the treatment with the acid not having been commenced until after the existence of complications, or from want of perseverance in following up the treatment, as from the rapid elimination of the acid from the system, it requires to be frequently and persistently administered in order to be of any avail. The acid may be given in doses of from 5 to 10 grains, repeated every hour or two. Without doubt the drug is practically useless in chronic cases. Prof. John M. Scudder believed the drug useful in cases of *acute*, or *sub-acute rheumatism*, with but little febrile reaction, the tongue being full, moist, purplish, or leaden-colored, and where the rheumatic area exhibits local redness, with slight purplish discoloration, especially when pressed upon; as an antirheumatic he preferred 2-grain doses every 2 hours. According to Prof. F. J. Locke, it is always contraindicated by a pointed, red tongue. He prefers to use it in combination with potassium acetate. It has likewise been used in *gout*, to lessen pain and favor the elimination of the sodic biurate present in the blood in excess, but it should not be administered to gouty patients whose urine contains albumen; though Dr. S. J. Sharkey and some others doubt whether the medicine has anything to do with the presence of albumen in the urine, as this substance is encountered in the urine of rheumatic

patients with high temperature; still, it is better to observe caution until the matter is settled definitely. In *acute diseases, intermittents, etc.*, it has failed as frequently as it has proved successful; and, indeed, doubts exist as to whether the successful results can be attributed to its action. It has been proclaimed useful in *aphthæ, thrush, lumbago, neuralgia, diabetes, hectic fever, etc.*, but further investigations are necessary before any reliance can be placed upon its use in these affections. As the rule, the administration of one of its salts is preferable to the pure acid, especially its sodium salt, on account of its more perfect solubility, its milder action, and its more agreeable taste. When salicylic acid, or any of its salts, is found to disagree with the stomach, occasioning uneasiness, nausea, or other unpleasant feelings, these may be prevented or mitigated by the administration of an aromatic tincture or infusion, with each dose. It is a good remedy in *dyspepsia* with yeasty fermentation. Given internally it removes *lumbricoides*, and by injection destroys the *ascaris vermicularis*.

As a local application, a spray of solution of salicylic acid has been found serviceable in *ozena, fetid bronchitis, chronic pharyngitis, aphthæ, pulmonary gangrene*, and other maladies attended with offensive odor, as *bad breath from carious teeth*; and it is a very efficient agent in *fetid perspiration*, especially of the feet and axillæ. In *phthisis* its use should be extremely guarded, as it has even produced hemoptysis in the healthy man. In *diarrhœa* and *dysentery*, also in *leucorrhœa* and *gleet*, used in injection, it has proven useful, especially in removing fetor; in these cases it should be used in solution considerably diluted, as a strong solution is apt to be quite irritating.

In diseases due to or attended with minute organizations (fungi), as *diphtheria, parasitic cutaneous maladies, hay fever, coryza, etc.*, its application in solution, or in dry powder, has been productive of benefit; in *ulcers, suppurating wounds, and gangrene*, it forms a very useful dressing, though probably inferior to thymol, or carbolic acid. Prof. Scudder regarded this agent as an antipytic, and considered it one of our best antiseptic agents. He employed it in open wounds to prevent the formation of pus, and to correct offensive odors. *Typhlitis* and *perityphlitis*, with or without suppuration, are benefited by it. It is valuable in *septicemia* to correct blood dyscrasia, and especially so in *puerperal fever* (Webster). Mixed with an ointment base, it has removed *freckles*, and combined with collodion and *cannabis indica*, has been recommended for the removal of *corns*. On account of its corrosive action on steel, it is not a good agent with which to cleanse surgical instruments. Dr. W. N. Mundy (*Annual of Eclectic Med. and Surg.*, Vol. 1), is authority for the statement that this acid is an excellent local application for *rhus poisoning*, and that a saturated solution with collodion will cure *ringworm*, a second application being rarely needed. Prof. A. J. Howe valued it in *pruritis ani* and *rectal fissures*. Lithium salicylate has given good results in *chronic cystitis*, and calcium salicylate has been highly praised for its action on *syphilitic chancre*.

Foltz reports good results in the scaly and exudative forms of *eczema* of the eyelids by the use of an ointment (salicylic acid [Lloyd's] grs. v to xx, petrolatum 3j), and also employed a 4 per cent glycerin solution to destroy the false membrane in *diphtheritic conjunctivitis*; while Webster regards it curative in *rheumatic ophthalmia* and in *myalgia* of the ocular region (*Dynam. Therapeutics*).

While salicylic acid and the salicylates are excellent remedies when indicated, they should be very cautiously employed where there is any existing *cardiac trouble*. In fact, the main objection to the use of these drugs is their dangerously depressant action on the heart. They are also contraindicated in *diseased conditions of the kidneys*, and especially so if disintegration of the renal structures is taking place. *Typhoid fever* and *typhoid states* are not benefited by this acid or its salts, but on the contrary their action is often deleterious. The untoward effects of the salicylates are said to be somewhat mitigated by the administration of ergot.

The following formulæ have been given for the administration and application of salicylic acid; the solutions, it will be observed, are salicylates of the alkalies entering into them: 1. Salicylic acid, 30 grs.; citrate of ammonium, 40 to 45 grs.; water, 4 fl℥. Mix. Or, salicylic acid, 30 grs.; citrate of ammonium, 15 grs.; rum or brandy, ½ fl℥; distilled water, 2½ fl℥. Mix. The dose is 1 to 2 tablespoonfuls (A. Casson). 2. Salicylic acid, 180 grs.; carbonate of

ammonium, 90 grs.; water, 6 fl̄. Mix. Dose, a tablespoonful every 3 hours (J. A. E. Stuart). 3. Salicylic acid, 60 grs.; borax, 30 grs.; glycerin, 1½ fl̄. Mix the acid and borax with half an ounce of the glycerin, and heat until solution is effected, then add the balance of the glycerin. For internal and local application. 4. Salicylic acid, 30 to 60 grs.; white wax, 60 grs.; paraffin, 120 grs.; almond oil, 2 drachms. Mix, melt, and rub up in a heated mortar. Spread on strips of muslin or fine linen. This is an excellent antiseptic application, and also useful in *eczema, rodent ulcer*, etc. (Lister). 5. Salicylic acid, 10 grs.; borax, 6 grs.; water, 6 fl̄. Mix, heat, and while the solution is hot, saturate clean cotton with it, and allow it to dry. This cotton forms a valuable dressing for surgical purposes. 6. Salicylic acid, 10 drachms; pure olive oil, 16 ounces. Mix, heat, and rub in a heated mortar. Lint or cotton saturated with this oily solution, forms a very satisfactory application to *burns, scalds, eczematous affections*, etc. Antirheumatic dose: 2 grains, in pill or capsule, every 3 hours, until 20 grs. are taken. Lotion: Salicylic acid, borax, āā 3j; aqua, Oj.

Specific Indications and Uses.—Antirheumatic; rheumatic pain, with but little fever; sub-acute rheumatism. Tongue, broad, full, purplish, or leaden-colored, showing spots where the fur is detached; chronic catarrh of mucous tissues.

Related Products.—ACIDUM SALICYLACTICUM, *Salicylactic acid*.—Salicylactic acid is obtained by heating 169 parts of dry sodium salicylate with 100 parts of a 40 per cent solution of caustic soda. After the mixture is cold add to it 130 to 140 parts of sodium monochloracetate, heat to 120° C. (248° F.), and then neutralize the mixture with diluted hydrochloric acid. It is insoluble in ether, which removes from it remaining traces of salicylic acid; and it is generally irresponsive to the common solvents. It is antiseptic, forming also an antiseptic salt when combined with antipyrin.

CRESOTIC ACID, Cresotinic acid, Homosalicylic acid, Oxytoluic acid ($C_6H_4CH_2OHCOOH$).—Many isomers of this acid exist, four of which are homologues to salicylic acid. Three of these are known as ortho-, meta-, and para-cresotic acids, according to their preparation from ortho-, meta-, or para-cresol, in the same manner as salicylic acid is obtained from phenol. Only the para compound is used medicinally, and that has been replaced by *sodium cresotate*. Paracresotic acid occurs in long prisms, fusing at 151° C. (303.8° F.), scarcely soluble in cold, but more readily in hot water, and easily soluble in alcohol, chloroform, and ether. *Sodium cresotate* is a fine, white powder, bitterish, but not unpleasant to the taste, and soluble in 24 parts of hot water, the solution being permanent. Divided doses of from 60 to 90 grains have been given daily, and it is said to act better as an antipyretic and antirheumatic than salicylic acid. On the other hand, it has been charged with causing cutaneous erythema and dangerous collapse.

SULPHOSALICYLIC ACID, Sulpho-salicylic acid, Salicyl-sulphonic acid ($C_6H_4SO_3H.OH.CO.OH$).—Produced by acting upon salicylic acid with concentrated sulphuric acid. Colorless needles soluble in water and alcohol. A delicate test for proteids—fibrin, globulins, peptones, and albumen, 17.17 part of the latter being detected by it. A dense white precipitate falls, which, when boiled, dissolves and reappears when the solution is allowed to cool, if the substance be an albumose or peptone. With the other bodies the precipitate does not redissolve on boiling.

ACIDUM PHENYLO-SALICYLICUM.—An acid whose salts are said to be less poisonous than those of salicylic acid, and possessing the germicidal properties of the latter. A powder, whitish, readily soluble in alcohol, glycerin, and ether, and sparingly in water.

ACIDUM ORTHO-AMIDO-SALICYLICUM.—A nearly odorless, non-crystalline, grayish powder, feebly sweetish, and not soluble in alcohol, water, or ether. Has been used by Neisser (*Inaug. Dissertation*, Bern, 1892) in sub-acute forms of *rheumatism*, with apparent success.

ACIDUM STEARICUM (U. S. P.)—STEARIC ACID.

FORMULA: $HC_{18}H_{35}O_2$. MOLECULAR WEIGHT: 283.38.

"An organic acid, in its commercial, more or less impure, form, usually obtained from the more solid fats, chiefly tallow"—(U. S. P.).

Source and Preparation.—Stearic acid may exist in limited quantities in a free state, and, together with palmitic acid, is present in the form of a glyceride in many of the oils and in most solid fats. It also exists free in the intestines when fats are undergoing digestion. It may be obtained pure by saponifying fats with an alkali, and decomposing the soap so formed with hydrochloric acid. The resulting fatty acids are dissolved in excess of alcohol and heated. The boiling solution is then acted upon with a strong solution of acetate of barium. The precipitate, after having been washed, is then decomposed with hydrochloric

acid, whereupon the stearic acid separates, and is treated with alcohol, from which it is recrystallized. Recrystallization is repeated until the crystals melt at about 70° C. (158° F.).

Description and Tests.—"A hard, white, somewhat glossy solid, odorless and tasteless, and permanent in the air. Insoluble in water; soluble in about 45 parts of alcohol at 15° C. (59° F.); readily soluble in boiling alcohol and in ether. Stearic acid when pure melts at 69.2° C. (156.6° F.). The commercial acid should have a melting point not lower than 56° C. (132.8° F.), and the melted acid should not become opaque and begin to congeal at a temperature lower than 54° C. (129.2° F.). If 1 Gm. of stearic acid and 1 Gm. of sodium carbonate be boiled with 30 Cc. of water in a capacious flask, the resulting solution, while hot, should not be more than opalescent (limit of undecomposed fat)"—(U. S. P.).

Uses.—This acid, combined with sal soda (sodium carbonate), is employed in the preparation of glycerin suppositories. The stearate of zinc forms a protective against fluids, and is useful as a dressing powder in *pruritic complaints*.

ACIDUM SULPHURICUM (U. S. P.)—SULPHURIC ACID.

FORMULA: H_2SO_4 . MOLECULAR WEIGHT: 97.82.

SYNONYMS: *Hydrogen sulphate, Oil of vitriol.*

Source and History.—Sulphuric acid is the most extensively used of the acids, being consumed in enormous quantities in almost every branch of commercial industry. It was first prepared (about 1440) from "calced vitriol" (green vitriol) by an industrious monk, Basil Valentine, of Erfurt, Saxony, and its composition ascertained by Lavoisier, in 1777. The name "oil of vitriol" was given it by the former. Combined in minerals, such as Epsom salts (magnesium sulphate), heavy spar (barium sulphate), and gypsum (calcium sulphate), it is quite extensively distributed over the earth. Unlike nitric and hydrochloric acids, it can not easily be made from its salts, but is prepared almost entirely by the oxidation of sulphur dioxide in the presence of water, the dilute solution being afterward concentrated. It is sometimes, though rarely, found uncombined in nature, the waters of the Rio Vinagre of South America containing it in sufficient quantities to render it appreciably sour. It exists free in the salivary glands of certain mollusca and in the waters of a few mineral springs—the Oak Orchard Mineral Spring at Medina, N. Y., containing 1½ Gm. to the liter.

Preparation.—Sulphuric acid is made in enormous quantities by passing into lead chambers, supported in a wooden frame-work, vapors of sulphur dioxide, nitric acid, jets of steam, and a certain quantity of atmospheric air. The sulphur dioxide is obtained by roasting iron pyrites, or burning crude sulphur; and the nitric acid, from the action of sulphuric acid on sodium nitrate. By a series of reactions of these substances on each other, a diluted acid, known as "chamber acid," results. This product is too weak for most industrial purposes (its density being 1.550), consequently it is drawn off into leaden evaporating pans, and condensed until its density reaches 1.750, when it begins to corrode the lead, and further concentration is carried on in glass or platinum stills.

Sulphuric acid for medicinal use can only be purified by distillation in glass retorts. This is a dangerous operation, from the fact that the retort is liable to be broken by the excessive heat required to bring the acid to the boiling point, 338° C. (640.4° F.). The glass retort must be imbedded to the neck in a sand-bath connected with a receiver, and heat applied. After about one-eighth or one-sixth of the acid has passed over, another receiver is connected in place of the former, which is removed, and the remaining distillate will then have the required density. No luting should be used to connect the retort and receiver, but a metallic hood over the former is advisable. To prevent bumping caused by the vapors, a few fragments of sharp-pointed glass, clay pipe-stems, or quartzite (Lembert), may be placed in the liquid in the retort, taking the precaution to replace them or add more as soon as their points become worn off. If possible, an acid free from arsenic should be employed for purification. Much of the English acid contains this impurity, on account of being made from iron pyrites, which contains it in considerable quantities. Acid made from Sicilian sulphur, however, is compara-

tively free from it, which is true also of much of the acid now made in this Country, though there have recently arisen factories in the United States, in which pyrites containing arsenic is employed. The removal of arsenic from sulphuric acid is carried out on a large scale according to either of the two following principles: 1. Precipitating the arsenic as sulphide by means of hydrogen sulphide, either in the concentrated, or preferably, the somewhat diluted acid. 2. By volatilizing the arsenic as trichloride by means of hydrogen chloride gas conducted into the acid, which is afterward heated to a temperature somewhat above 134°C . (273°F .) to facilitate the expulsion of the arsenous chloride. If arsenic is present in the form of arsenic acid, this must first be reduced to arsenous acid, by means of sulphurous acid gas, or heating the acid with a little charcoal.

FUMING SULPHURIC ACID, *Acidum sulfuricum fumans*.—This acid is also known as *Nordhausen oil of vitriol*, from the fact that it was first made at Nordhausen, in Saxony. It was prepared at an earlier date than ordinary oil of vitriol. It is really a sulphur trioxide (SO_3) dissolved in sulphuric acid, and is made by roasting ferrous sulphate (obtained from pyrites-bearing slate) to redness in earthenware retorts, and distilling. The acid fumes pass over, leaving ferric oxide in the retort. The latter is then sold as a polishing material, under the name of *colcothar* or *rouge*.

Description.—I. **SULPHURIC ANHYDRID, or *Anhydrous sulphuric acid* (SO_3),** is a white, crystalline solid, which melts at 20°C . (68°F .), and boils near 35°C . (95°F .). It gives off thick fumes in moist air, and has so strong an affinity for the elements of water that when thrown into that fluid it hisses like red-hot iron, combining with the water to form oil of vitriol. It is prepared from the Nordhausen acid. It does not redden litmus unless moisture be present.

II. **NORDHAUSEN OIL OF VITRIOL,** is an oily fluid, usually brownish in color from organic impurities present. It gives off copious, white, irrespirable fumes; when cooled to 0°C . (32°F .) it congeals, forming white crystals of the composition $\text{H}_2\text{SO}_4 + \text{SO}_3$, and melting at 35°C . (95°F .). This compound is called pyrosulphuric acid ($\text{H}_2\text{S}_2\text{O}_7$), because it forms a number of stable salts. It boils when heated to between 40°C . (104°F .) and 50°C . (122°F .), yielding anhydrous sulphuric acid.

III. **COMMERCIAL OIL OF VITRIOL.**—Crude sulphuric acid is of a heavy, oily consistence, odorless, and colorless if free from organic matter. It is often, however, of a yellowish or dark-brown appearance, due to the presence of such organic material as dust, cork, straws, etc., and will quickly disintegrate flesh. Even after much dilution it has an intensely sour taste. It should be free from arsenic if to be used for pharmaceutical purposes, but unfortunately this impurity, as well as lead sulphate, is frequently present.

IV. **ACIDUM SULPHURICUM (U. S. P.), *Sulphuric acid*.**—"A liquid composed of not less than 92.5 per cent, by weight, of absolute sulphuric acid ($\text{H}_2\text{SO}_4 = 97.82$), and not more than 7.5 per cent of water. The above-named percentage (92.5) is that assumed for sulphuric acid in the formulæ of pharmacopœial preparations. Sulphuric acid should be kept in glass-stoppered bottles"—(U. S. P.).

It forms "a colorless liquid, of oily consistence, inodorous, and very caustic and corrosive. Specific gravity, not below 1.835 at 15°C . (59°F .). Miscible in all proportions, with water and alcohol, with evolution of so much heat that the mixture requires great caution. It boils at 338°C . (640.4°F .). When heated on platinum foil it is vaporized without leaving a residue. Even after dilution with much water it shows an intensely acid reaction with litmus paper"—(U. S. P.).

Owing to its great affinity for water, sulphuric acid is so intensely corrosive that it will rapidly destroy the tissues. If a piece of wood or a lump of sugar be dipped into the acid it will abstract from it the elements of water, leaving behind a charred mass of carbon. When mixed with water a great amount of heat is developed, depending partly on the energetic chemical action, and partly on the condensation which takes place; on this account, when exposed to the atmosphere, its absorption of moisture rapidly reduces its strength. It unites with water in all proportions, and the heat evolved is so great as to endanger the glass container, which may be avoided by adding the acid gradually. Water should never be poured into the acid, but, on the contrary, if a solution be required, the

acid should be gradually added to the water, and, preferably, a porcelain dish should be used in which to mix it. Combined with bases, sulphuric acid forms salts called sulphates.

V. ACIDUM SULPHURICUM DILUTUM (U. S. P.).—Diluted sulphuric acid.

Preparation.—"Sulphuric acid one hundred grammes (100 Gm.) [3 oza. av., 231 grs.]; distilled water eight hundred and twenty-five grammes (825 Gm.) [1 lb. av., 13 oza., 44 grs.]. To make nine hundred and twenty-five grammes (925 Gm.) [2 lbs. av., 275 grs.]. Pour the acid gradually, under constant stirring, into the distilled water. Keep the product in glass-stoppered bottles"—(U. S. P.).

Description.—This is a thin, colorless liquid, having a pure, sour taste. "Diluted sulphuric acid contains 10 per cent, by weight, of absolute sulphuric acid. Specific gravity about 1.070 at 15° C. (59° F.). It should respond to the reactions and tests given under sulphuric acid (see *Acidum Sulphuricum*). To neutralize 4.89 Gm. of diluted sulphuric acid should require 10 Cc. of normal potassium hydrate V.S. (each Cc. corresponding to 1 per cent of the absolute acid), phenolphthalein being used as indicator"—(U. S. P.).

Impurities and Tests.—Among the impurities liable to be found in sulphuric acid are: Organic matter, which colors the acid brownish or black; arsenic, which may be detected by Marsh's test, or according to the U. S. P. test to follow; selenium, which, when the acid is diluted with alcohol, falls down in the form of a red powder. The presence of sulphuric acid in the smallest quantity, whether free or combined, is detected in solutions by the characteristic property of forming, with any soluble compound of barium (as the chloride or nitrate), a precipitate of sulphate of barium, which is not only insoluble in water, but also in strong acids, except in concentrated sulphuric acid; from this solution it is reprecipitated by water. Free sulphuric acid in dilute solution may be recognized, by adding some crystals of sugar and evaporating on the water-bath nearly to dryness, whereby a black or brown color is produced if sulphuric acid was present. Sulphuric acid reddens salicin, piperin, veratrine, phloridzine, oil of bitter almonds, etc.

The U. S. P. tests for the purity of sulphuric acid, are as follows: "Diluted with 5 volumes of water, it yields, with barium chloride T.S., a white precipitate insoluble in hydrochloric acid. On mixing the acid, carefully, with 4 or 5 volumes of alcohol, no precipitate should be formed within one hour (absence of lead). If there be carefully poured upon it, in a test-tube, a layer of ferrous sulphate T.S., the zone of contact should not assume a brown or reddish color (limit of nitric or nitrous acid). In sulphuric acid, diluted with 20 volumes of water, no precipitate should be formed by the addition of silver nitrate T.S. (absence of hydrochloric acid), or of hydrogen sulphide T.S. (absence of lead, arsenic, copper); nor by supersaturation with ammonia water (iron); nor should the acid thus supersaturated leave any fixed residue on evaporation and ignition (absence of non-volatile impurities), nor yield any precipitate on addition of ammonium sulphide T.S. (iron, thallium, etc.). 1 Cc. of sulphuric acid, diluted with 5 Cc. of water, and cooled, should not at once discharge the color of 0.1 Cc. of decinormal potassium permanganate V.S. (limit of sulphurous or nitrous acid). If 1 Cc. of a mixture of 1 volume of sulphuric acid with 2 volumes of water be mixed with 1 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), and a small piece of pure tin-foil added, no coloration should appear within one hour (limit of arsenic). To neutralize 0.489 Gm. of sulphuric acid, diluted with about 10 Cc. of water, should require not less than 9.25 Cc. of normal potassium hydrate V.S. (each 0.1 Cc. corresponding to 1 per cent of the absolute acid), phenolphthalein being used as indicator"—(U. S. P.).

Uses in the Arts and Pharmacy.—Sulphuric acid is very extensively used in almost every branch of the arts. In pharmaceutical operations it is the most universally employed of all acids, viz.: To liberate hydrogen from zinc and water; in purifying chloroform and other bodies, by extracting organic impurities; for drying gases and other bodies; in the preparation of many other acids; to refine paraffine and petroleum products; in preparing the aromatic sulphuric acid, the sulphates, sulphurous acid, oil of wine, sulphuric ether, alkaloids, pyroxylin, hides for tanning, chlorinated lime, phosphorus, soda, alum, persulphate of iron; and in making solutions of indigo, etc.

Action and Toxicology.—The protracted use of diluted sulphuric acid, is exceedingly deleterious in its effects on digestion, and may give rise to diarrhoea, with consequent weakness and loss of flesh. It is at all times and in all conditions destructive to the teeth. It slows the pulse, increases the appetite, allays thirst, and checks excessive cutaneous excretion. Injected into the venous circulation, the strong acid coagulates and chars the blood. The pure acid destroys flesh, redissolving coagula, and penetrates deeply, carbonizing the tissues wherever it touches. If swallowed in any amount, death is almost sure to follow, as the tissues over which it passes are utterly destroyed. The symptoms are intense burning pain, escape of gaseous or frothy material, retching, and vomiting of shreds of tissue and dark, coffee-ground and bloody fluid, and excoriation of the parts over which the acid passes, giving them a whitish appearance, as of parchment that has been soaked. This whitish hue subsequently changes to gray or brownish, and the mouth is filled with a thick, sticky mixture of mucus, saliva, and corroded tissue. Breathing, speaking and swallowing are very difficult, and the face assumes a livid or bluish appearance. If breathing be not obstructed, from injury to the larynx, the face is pale and the expression extremely anxious and indicative of intense suffering. Pain is increased upon the ingestion of fluids, and upon movement of the abdominal muscles. Exhaustion, great weakness, small, feeble, quick pulse, cold, mottled skin, bathed in clammy sweat, great thirst, obstinate constipation and convulsive movements, are also symptomatic. The intellect remains unimpaired until death. If death is not immediately produced, it may subsequently result from œsophageal stricture, or gastric inflammation and ulceration; in either case causing death by starvation. It should be antidoted with calcined magnesia, if at hand; if not, other alkaline solutions may be given. Emetics and alkaline carbonates should, if possible, be avoided, and the stomach-pump used with the greatest of care. Mucilaginous drinks, milk, albumen and soaps may be given after the antidotes if the acid swallowed be small in amount, or in a diluted form. After death, the parts are found corroded, and colored whitish, gray or brown-black, with ecchymoses. The stomach may be perforated, but if not, it is collapsed and its tissues contracted, the stain being black or brown over the entire surface, or merely in black streaks, according to the amount of food in the organ. The contents are of the same hue, and tarry in consistence. If perforation occurs, other neighboring organs may be attacked. Death from poisoning by this acid, usually occurs in from 18 to 24 hours. The smallest dose which has killed is $\frac{1}{4}$ drachm. A middle-aged man died in three-quarters of an hour from $3\frac{1}{2}$ ounces of the acid (Rapp). Again, death may result months or years afterward from the effects of the poison.

If the acid be spilled, upon the skin brown spots may appear, or the color of clothing may be changed to red or yellow, or wholly discharged; if the goods be black, a moist, reddish-brown stain is seen.

Medical Uses and Dosage.—Externally, sulphuric acid has been used as a caustic, in *ulcers* and *malignant growths*, combined with enough saffron or sulphate of zinc to form a paste that will not spread beyond the part to which it is applied. It has been used in *entropion* and *ectropion*, to cicatrize the palpebral tissues in such a manner as to reverse the direction of growth. It is sometimes used in the form of ointment. As an internal remedy, it is only used in a diluted form. Diluted sulphuric acid is an excellent tonic, exciting the appetite, promoting digestion, quenching thirst, and checking fermentation in the stomach, and is therefore used with success in morbid acidity, debility, and relaxation of the stomach. As an astringent, it is used in *hemorrhages* of a passive character, *diarrhoea*, *chronic dysentery*, *Asiatic cholera*, etc. As a refrigerant, it is very useful in checking the perspiration in *hectic fever*; and forms a pleasant acid drink, when sufficiently diluted with water, in *continued fevers*, and during recovery from exhausting diseases; as an antiseptic, it is beneficial in putrid febrile diseases. It is an effectual remedy in *lead poisoning* or *painter's colic*, as are all of the soluble sulphates. As a remedy for *colliquative sweating*, it is probably one of the best we possess. For this use the aromatic acid is generally preferred. As a diuretic, it may be used in *dropsies*, and some forms of *fever*, but its use should not be continued too long, as it is apt to cause griping and looseness. It has likewise been advantageously exhibited in some *cutaneous diseases*, *phosphatic*

calculous affections, dyspepsia, etc. Added to gargles, it will be found of service in *ulceration of the throat and mouth, profuse salivation, etc.*; and may be used in the form of a wash in *indolent ulcers, and several diseases of the skin.* The dose of the strong acid is 1 or 2 drops largely diluted (water flʒvj); of the diluted acid 5 to 30 drops, well diluted in about 4 fluid ounces of water. Alkaline washes should follow to protect the teeth.

Specific Indications and Uses.—The deep-red tongue; diarrhoea, with deep-red tongue and gastric debility; colliquative sweats, with marked debility.

ACIDUM SULPHURICUM AROMATICUM (U. S. P.)—AROMATIC SULPHURIC ACID.

SYNONYMS: *Elixir of vitriol, Elixir vitrioli Mynsichti, Tinctura aromatica acida, Mynsicht's elixir.*

Preparation.—Sulphuric acid, one hundred cubic centimeters (100 Cc.) [3 flʒ, 183 M]; tincture of ginger, fifty cubic centimeters (50 Cc.) [1 flʒ, 331 M]; oil of cinnamon, one cubic centimeter (1 Cc.) [16 M]; alcohol, a sufficient quantity. To make one thousand cubic centimeters (1000 Cc.) [33 flʒ, 391 M]. Add the sulphuric acid gradually and with great caution to seven hundred cubic centimeters (700 Cc.) [23 flʒ, 321 M] of alcohol, and allow the mixture to cool. Then add to it the tincture of ginger and the oil of cinnamon, and afterward enough alcohol to make the whole measure one thousand cubic centimeters (1000 Cc.) [33 flʒ, 391 M]. Keep the product in glass-stoppered bottles (U. S. P.).

Description.—This forms a pleasantly aromatic, acid preparation, having a pale-yellow color. "Aromatic sulphuric acid contains about 20 per cent, by weight, of official sulphuric acid, partly in form of ethyl-sulphuric acid. Specific gravity, about 0.939 at 15° C. (59° F.). If 4.89 Gm. of aromatic sulphuric acid be mixed in a small flask with 15 Cc. of water and boiled for several minutes (so as to decompose the ethyl-sulphuric acid), and the liquid be then allowed to cool, it should require, for complete neutralization, about 18.5 Cc. of normal potassium hydrate V.S. (each Cc. corresponding to 1 per cent of absolute or about 1.08 per cent of official sulphuric acid), phenolphthalein being used as indicator"—(U. S. P.) The sulphovinic acid (ethyl-sulphuric acid) developed in this preparation gradually increases as the product becomes old. The corresponding British preparation contains only a little over 12 per cent of sulphuric acid, and has a density of 0.911.

Medical Uses and Dosage.—This acid mixture possesses the same properties as diluted sulphuric acid, for which it is preferable, and generally substituted for internal administration. It is particularly applicable in *colliquative sweating*, and in *gastric derangements.* It may be given in doses of 5 to 30 drops, diluted with about 4 fluid ounces of water, and repeated 3 or 4 times a day. The teeth may be protected from the action of the acid, by taking it through a glass tube and employing thereafter an alkaline wash.

Specific Indications and Uses.—The deep-red tongue; diarrhoea, with the deep-red tongue and gastric debility; colliquative sweats, with marked debility.

ACIDUM SULPHUROSUM (U. S. P.)—SULPHUROUS ACID.

FORMULA: SO_2 . **MOLECULAR WEIGHT:** 63.9.

SYNONYMS: *Sulphur dioxide, Sulphurous anhydride.*

"A liquid composed of not less than 6.4 per cent, by weight, of sulphurous acid gas (sulphur dioxide, $\text{SO}_2=63.9$), and not more than 93.6 per cent of water"—(U. S. P.).

History and Source.—The ancient Greeks and Romans were acquainted with the characteristic bleaching and disinfecting properties of sulphur fumes, and, according to Pliny, they were employed for purifying fabrics. Stahl, in 1697, differentiated the dioxide from oil of vitriol, and in 1775, sulphur dioxide was prepared pure, and investigated by Priestly (Roscoe and Schorlemmer). It exists in some mineral springs, in volcanic gases, and is formed whenever sulphur

is burned in the atmosphere. Medicinal sulphurous acid, is a solution of sulphur dioxide in water, and has the formula, H_2SO_3 .

Preparation.—On a small scale, sulphurous acid is obtained either by acting upon sodium sulphite with diluted sulphuric acid, or reducing sulphuric acid by heating with copper turnings, or with sulphur, or more generally with charcoal; in the latter case the following reaction takes place: $2\text{SO}_3\text{H}_2 + \text{C} = \text{CO}_2 + 2\text{H}_2\text{O} + 2\text{SO}_2$. The process indicated as follows by the *U. S. P.* is representative:

"Sulphuric acid, eighty cubic centimeters (80 Cc.) [2 fl \bar{z} , 338 Ml.]; charcoal, in coarse powder, twenty grammes (20 Gm.) [309 grs.]; distilled water (1000 Cc.) [33 fl \bar{z} , 391 Ml.]. Introduce the charcoal into a glass flask having a capacity of about five hundred cubic centimeters (500 Cc.) [16 fl \bar{z} , 435 Ml.]; add the acid, and mix them well. Connect the flask, by means of suitable glass tubing, with a wash-bottle having a capacity of about two hundred cubic centimeters (200 Cc.) [6 fl \bar{z} , 366 Ml.], which is filled to about one-third of its height with water. Through the stopper of the wash-bottle pass a safety-tube, which should reach nearly to the bottom of the bottle, and connect the latter, by means of glass tubing, with a bottle having a capacity of about fifteen hundred cubic centimeters (1500 Cc.) [about 50 fl \bar{z}], and containing one thousand cubic centimeters (1000 Cc.) [33 fl \bar{z} , 391 Ml.] of distilled water deprived of air by being boiled shortly before use. The tube should dip about 25 Mm. below the surface of the distilled water. By means of a second tube, connect this bottle with another containing a dilute solution of sodium carbonate, to absorb any gas which may not be retained by the distilled water. Having ascertained that all the connections are air-tight, apply a moderate heat to the flask containing the sulphuric acid and charcoal, until the evolution of gas has nearly ceased, and during the passage of the gas keep the bottle containing the distilled water at or below 10° C. (50° F.) by surrounding it with cold water or ice. Finally, pour the sulphurous acid into dark, amber-colored, glass-stoppered bottles, and keep them in a cool place, protected from light"—(*U. S. P.*).

In the preparation of sulphurous acid on a somewhat larger scale, Prof. J. U. Lloyd has, to great advantage, replaced the glass apparatus by a cast-iron retort of about 2 gallons capacity.

Description and Tests.—I. **SULPHUROUS ANHYDRIDE.**—Sulphurous acid gas is colorless, irrespirable, having the odor of burning sulphur, and an acid taste. It is very heavy, having the specific gravity 2.2112, forms an anhydrous, limpid liquid at -10° C. (14° F.), and at a very low temperature it solidifies. Respired in a concentrated form, it proves fatal to life; if diluted, it causes cough and headache. It is highly destructive to all animals. Its reaction in aqueous solution is strongly acid. It extinguishes combustibles in a state of flame, and in case of burning soot in a chimney, a handful of sulphur thrown into the fire will promptly extinguish it if the draft be closed. It bleaches many vegetable and animal colors, and its vapor, from burning sulphur, is used to whiten straw, bleach silk, woolen goods, and isinglass—in fact, is used for bleaching where chlorine can not be utilized or would be injurious. Brewers use a solution of sulphurous acid to cleanse casks that have been once used, and farmers make common use of the fumes of burning sulphur in purifying cider barrels. It is sometimes employed for the preservation of meats and canned fruits. It will remove fruit stains, and is employed by the pharmacist to bleach sponges. In combination with bases, its aqueous solution gives rise to the line of salts known as the sulphites. When dry, it shows no affinity for oxygen, but in contact with a little water it slowly combines with that gas, forming sulphuric acid.

II. **SULPHUROUS ACID.**—Sulphurous acid of the *U. S. P.* contains 6.4 per cent of absolute acid. It is "a colorless liquid, of the characteristic odor of burning sulphur, and of a very acid, sulphurous taste. Specific gravity not less than 1.035 at 15° C. (59° F.). By heat it is completely volatilized. Litmus paper moistened with the acid is first reddened and afterwards bleached"—(*U. S. P.*).

"On gently heating a few Cc. of the acid in a test-tube, the gas evolved will blacken a strip of paper moistened with mercurous nitrate T.S., but will not affect one moistened with lead acetate T.S. On mixing in a test-tube 1 Cc. of sulphurous acid with 5 Cc. of diluted hydrochloric acid, and adding a small piece of pure zinc, hydrogen sulphide gas will be evolved, which will

blacken a strip of paper moistened with lead acetate T.S. If to 10 Cc. of sulphurous acid there be added 1 Cc. of diluted hydrochloric acid, and afterwards 1 Cc. of barium chloride T.S., not more than a very slight turbidity should be produced (limit of sulphuric acid). If 2 Gm. of sulphurous acid be diluted with 25 Cc. of distilled water and a little starch T.S. be added, at least 40 Cc. of decinormal iodine V.S. should be required before a permanent blue tint is developed (each Cc. corresponding to 0.16 per cent of sulphur dioxide)"—(U. S. P.).

Action, Medical Uses, and Dosage.—Organic matter is energetically attacked by this acid, which has a selective affinity for oxygen. Fungi, bacteriæ, and other low forms of life, are destroyed by it. Pronounced irritation of the glottis is produced by inhaling sulphur dioxide, and the sensation of suffocation produced is intense. The air passages may be violently inflamed by large amounts of the gas. Fatal cases from the burning of coal giving off a large amount of this gas, present a cold surface, livid countenance, purple lips, hands, and nails; short, quick breathing; quick, feeble, and small pulse; fixation of the pupils, and complete insensibility. Congestion of the brain, heart, and lungs is, as a rule, the chief post-mortem feature, like one who has been hanged (see Taylor).

Sulphurous acid was introduced into medicine owing to its destructive influence upon inferior organic growths, whether animal or vegetable, and from its apparent azymotic property. It has been found very useful in *typhoid* or *enteric* and *remittent fevers*, *scarlet fever*, *smallpox*, *measles*, *puerperal* and *surgical fevers*, and in *dysentery* and *pneumonia*, both of typhoid type, in *sarcinæ ventriculi*, and in *pyrosis*, checking the excessive secretion, stopping the vomiting, and lessening epigastric pain. Dr. H. Lawson has found the fluid of pyrosis to contain *sarcinæ*, *torulæ*, huge clusters of *leptothrix*, and myriads of vibriones and bacteriæ, which, by their presence, keep up the irritation causing pyrosis; the sulphurous acid checks these unusual processes by its parasitocidal properties. He advised from half a drachm to a drachm, 3 times a day, shortly before meals, largely diluted with distilled water. Yeasty fermentation calls for it. The sulphites of sodium or magnesium produce similar results, as they become decomposed when in the stomach, and give out sulphurous acid.

To be of service in the foregoing disorders, as well as in those to follow, this agent must be specifically applied. The cases for it are those calling generally for acid medication; though it is not used as an acid, for its acid properties are feeble. Yet the general state of the system tends toward excessive alkalinity (redness), while, on the contrary, the alkaline sulphites are indicated in excessive acidity (pallid tongue and membranes). The characteristic condition for sulphurous acid, is one of a low state, with normal or increased redness of the tongue and membranes. The tissues are enfeebled, full and relaxed, and appear to have lost vitality; the pulse large and empty, the sensation under the finger being that of a large-calibred vessel with a small stream of blood. The secretions are nasty, dirty, and exhale, as well as the breath, a peculiar, sweetish, mawkish odor. The membranes are reddened and dirty, or muddy in color. The tongue is characteristic, being coated, over red, with a glutinous, nasty, yellowish-brown, or the coating may be transparent; and, again, it may appear as if fecal matter had been rubbed upon it. In later stages a moist, glutinous, brownish fur may line the center of the organ. Occasionally the tongue is slick and shining, like a piece of raw beef. Dirty sordes upon the teeth and lips; and the saliva is increased in quantity, viscid, and mawkish. When externally indicated, as in *erysipelas* and like conditions, the tissues are deep-red, and appear to have lost vitality. The erysipelatous redness blanches more or less as the disease progresses, "sometimes in the center, sometimes at the border, sometimes in the deep structures, you seem to be looking through the superficial redness" (Scudder, *Spec. Diag.*, 90). *Wounds* and *abrasions* seem to show a tendency to slough, and are bathed in dirty, sticky, unhealthy secretions. Added to these a depraved state with *yeasty vomiting*, and you have the uses for one of our most important antiseptics.

Sulphurous acid has been largely employed as an external application in all *cutaneous parasitic affections*, and in which, before its application, the scabs have been removed, so as to have the diseased surface directly exposed to the agent. For this purpose it may be applied pure, or diluted with glycerin or water, of the required strength. The use of glycerin, however, should be guarded, as it often

acts as an irritant to the skin, as well as doing injury by abstracting water from the tissues, leaving them hard and dry. *Tinea tonsurans*, *verruccolor*, and *favosa*, *urticaria*, *scabies*, *ringworm*, and *purpura*, are successfully treated with it. As a wash, or in the form of spray, it has been found effectual in *thrush*, *diphtheria* (with dusky coloration of membranes), *follicular pharyngitis*, *clergyman's sore throat*, *chronic irritation of the larynx and vocal cords*, *weakness or loss of voice* from the preceding cause, *chronic bronchitis*, *pertussis*, *asthma*, *wounds*, and *ulcers*. In these conditions it should be used internally also. *Mucous patches*, *tonsillitis*, and *mercurial stomatitis*, when having the characteristic indication, yield promptly to this acid. As an application to *sloughing wounds* and *ulcers*, with sticky, glutinous secretion, it is of marked value. Give it internally at the same time.

Cures have been effected in several cases of extensive *syphilitic ulceration* of the throat and posterior nares, by the spray, repeated 2 or 3 times a day, of sulphurous acid, used of official strength, or diluted with an equal volume of water. It is equal, if not superior to carbolic acid, in efficiency, besides being free from the objections to the latter, as, its disgusting odor and its powerful, irritant action. Dr. James Dewar has found sulphur dioxide very efficacious in *pleuropneumonia of cattle*, *chilblains*, *chapped hands*, *obstinate grease of the heels in horses*, *ringworm*, *molluscum*, *mange*, *lice*, *hospital gangrene*, and as a disinfectant; having in all these difficulties made use of it in the form of sulphur fumigation, paying proper attention to ventilation of the apartment in which the cattle or persons are exposed to the vapor. He has even met with unexpected success in a case of supposed *phthisis*, with which several other eminent medical men were acquainted. We can not, however, subscribe to its alleged curative action in the last-named disease, though we believe it to be valuable in mitigating many of the unpleasant symptoms, and particularly in overcoming the sweetish, mawkish odor of the sputa and breath. As a decalcifying agent to assist in the removal of carious fragments from the aural canal and tympanum, it has found some favor. Dose, from 10 to 60 drops, well diluted. The acid must be fresh, and not remain long in contact with water. Dispense it in bulk.

Specific Indications and Uses.—Full, relaxed, dirty-looking tissues, with deep redness and sticky, unhealthy discharges; sweetish, mawkish odor of breath and discharges; saliva increased and viscid; tongue full, broad, atonic, normally red, with glutinous coat, either transparent or dirty-brownish, with effaced papillæ; unhealthy, viscid wounds and ulcers; gastric derangements with yeasty fermentation. All the conditions are those of sepsis and debility.

ACIDUM TANNICUM (U. S. P.)—TANNIC ACID.

FORMULA: $\text{HC}_6\text{H}_3\text{O}_6$. MOLECULAR WEIGHT: 321.22.

SYNONYMS: *Gallotannic acid*, *Digallic acid*, *Tannin*, *Tanninum*.

"An organic acid obtained from nutgall"—(U. S. P.).

Source.—Tannin is a name applied to vegetable substances possessing acid properties and having an astringent taste, and which produce with iron salts a dark precipitate or solution, and precipitate albumen and gelatin. The tannin under consideration is produced from nutgalls, and to distinguish it from other tannins, is known as gallotannic or digallic acid. Tannic acid may be obtained from nutgalls (excrecence on *Quercus lusitanica*, Lamarck, *var. infectoria*, Nat. Ord. *Cupuliferae*, U. S. P.), from the leaves of the *Rhus Coriaria*, Linné, from some kinds of acorn cups, and from Japanese and Chinese galls. Allied tannic acids are also found in catechu, coffee, fustic, quercitron, pomegranate, kino, cinchona, tea, the oak, willow, elm, horse-chestnut, plum, pear, sumach, whortleberry, etc., in each instance possessing nearly the same properties, though their chemical composition is different. Some of them form a dark-green color with the salts of iron, and a few form a gray color. Gallotannic acid produces a dark-blue, or bluish-black precipitate with ferric salts. Tannic acid was distinguished as an individual compound by Deyeux and Seguin, in 1793 and 1795, respectively. Gallotannic acid was found by Schiff, in 1871, to be an anhydride of gallic acid, having the constitutional formula: $\text{CO}_2\text{H} \cdot \text{C}_6\text{H}_3(\text{OH})_2 \cdot \text{O} \cdot \text{COC}_6\text{H}_3(\text{OH})_2$.

Preparation.—Allow sulphuric ether to percolate through a suitable quan-

tity of powdered galls contained in a glass percolator, the lower end of which is loosely closed with a pellet of cotton. The liquor obtained in the receiver separates into two parts, and the ether must be allowed to percolate through the galls until the lower stratum of liquid in the receiver no longer increases. Pour off the upper layer, and evaporate the lower portion with a moderate heat, to dryness.

It is stated that a much larger quantity of tannic acid may be obtained by employing a mixture of 16 parts of ether and 1 part of alcohol. The percolated liquid separates into two layers. The lower one contains the tannic acid, which may be obtained perfectly pure on evaporation; the upper layer contains the gallic acid, coloring matter, and some tannic acid. The tannic acid in the upper layer may be obtained by evaporating the liquid to dryness, treating the residue with pure ether, until the lower of the two layers, into which the liquid separates, no longer presents a green color; and then separating it, adding, if necessary, a little alcohol, and evaporating.

Description and Tests.—"A light-yellowish, amorphous powder, usually cohering in form of glistening scales or spongy masses; odorless, or having a faint, characteristic odor, and a strongly astringent taste; gradually turning darker when exposed to air and light. Soluble at 15° C. (59° F.) in about 1 part of water, and in 0.6 part of alcohol; very soluble in boiling water, and in boiling alcohol; also in about 1 part of glycerin, with the intervention of a moderate heat; freely soluble in diluted alcohol, sparingly in absolute alcohol; almost insoluble in absolute ether, chloroform, benzol, or benzin. When heated on platinum foil, the acid is gradually consumed without leaving more than 0.2 per cent of ash. Tannic acid has an acid reaction upon litmus paper"—(*U. S. P.*).

The watery solution, exposed to the air, absorbs oxygen, and is transformed into carbonic acid gas, which escapes, leaving behind gallic and ellagic acids. Oils do not dissolve it. Tannic acid combines with a solution of animal gelatin, forming a white, curdy, insoluble substance, the tannate of gelatin; a piece of prepared skin introduced into a solution of tannic acid, absorbs the acid and is converted into leather. With the per-salts of iron, tannic acid and its salts strike a deep-blue, nearly black color, which is a tannate of iron, and the principal ingredient of ordinary ink. Ink stains are gallo-tannates of iron, and are readily removable by oxalic and citric acids, owing to the solubility of the iron basis. When potassium hydroxide is added in excess to a solution of tannic acid, tannoxylic or rubitannic acid is formed; if the mixture be boiled, instead of exposed to the air, tannomelanin or tannohumic acid is formed, a bibasic, dark, humus-like powder. Concentrated sulphuric acid dissolves the dry tannins, forming yellow solutions which, when heated, become deep-red, owing to the formation of rufi-gallic and meta-gallic acids. Potassium bichromate causes brown precipitates with the majority, if not all, of the tannins (*Trimble, On Tannins*). Tannic acid precipitates most metallic oxides from the solution of their salts; is more or less completely precipitated from its solution by mineral acids, and gives, with those acids, compounds soluble in pure water. If tannic acid be treated with oxidizing bodies, as with nitric acid, chromic acid, chlorine, bromine, or the higher oxides, it is completely destroyed, under production of formic and oxalic acids. Acetate of lead added to a solution of tannic acid, produces a white precipitate; tartar emetic gives a white precipitate, of a gelatinous character. When given internally, tannic acid will be found, when passed in the urine, to have changed into gallic acid. There is a substance formed in white wines, called glaiadine, which renders them turbid and disposed to mucous fermentation; a solution of tannic acid will arrest this by coagulating the above-named substance.

The *U. S. P.* gives the following tests: "The addition of a small quantity of ferric chloride T.S. to an aqueous solution of the acid, produces a bluish-black color or precipitate. On adding to an aqueous solution (1 in 100) of tannic acid a small quantity of calcium hydrate T.S., a pale, bluish-white, flocculent precipitate is produced which is not dissolved on shaking (difference from gallic acid), and which becomes more copious and of a deeper blue by the addition of a moderate excess of calcium hydrate T.S., while a large excess of the latter imparts a pale-pinkish tint to the solution. The aqueous solution of the acid produces precipitates with most alkaloids and bitter principles, and with test

solutions of gelatin, albumen, and starch (distinction from gallic acid). On dissolving 2 Gm. of tannic acid in 10 Cc. of boiling water, and allowing the liquid to cool, no turbidity should be produced on diluting 5 Cc. of the solution with 10 Cc. of alcohol (absence of gum or dextrin), or with 10 Cc. of water (absence of resin)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Tannic acid is a pure astringent. It has a bitter, astringent taste, and a constricting action upon mucous tissues. As a general rule it does not derange the stomach, yet it precipitates pepsin from the gastric secretions. It generally produces constipation, by contracting the intestinal vessels, thus diminishing the secretions and retarding peristaltic action. It sometimes, and especially when long given, occasions gastric and intestinal pain, febrile phenomena, with thirst and eructations of gas, while the tongue is coated, and defecation tenesmic. It powerfully coagulates blood and albumen, and enters into the blood in the form of gallic acid. It probably controls hemorrhage by acting upon the vascular coats. Erythema, dyspnea, and a cyanotic condition have been produced by it.

In view of its astringent power, tannic acid is very valuable in *gastro-intestinal disorders*, with undue acid, watery, or mucoid secretions, and accompanied with flatulence. In the various forms of *non-irritative diarrhæa*, without fever or inflammation, it is of marked utility. *Chronic dysentery* is asserted to be benefited by it. Tannic acid should never be given when there is fever or active inflammation. The *diarrhæa* and *colliquative sweats of phthisis* are controlled by it, the febrile condition here, if present, not contraindicating its use. It is effectual in *uterine* and other *passive hemorrhages*, and as a wash or injection to remove chronic mucous discharges, as in *bronchial catarrh*, *gonorrhæa*, *gleet*, *leucorrhæa*, etc. "Use it in *hemorrhage*, from abortion, or any passive uterine hemorrhage, with pain and nervous disturbance. Take 30 grains each, of tannic acid and Dover's powder, and divide into 5 or 10 powders, and let 1 be taken every hour or two until the bleeding is arrested. This will check the flow, provided there is no organic lesion" (*Locke, Syl. of Mat. Med.*). In this manner it is of much value in *menorrhagia*. *Hematuria*, *hematemesis*, and *hemoptysis* (by spray) are benefited if the blood is small in amount. If the hemorrhage be active in the latter case, the agent is too slow in producing its effects. It has likewise been recommended in *diabetes*, combined with opium, and to arrest excessive perspiration; also, in conjunction with morphine, in *Asiatic cholera*. Externally, it has been successfully used in *excoriations*, *prolapsed ani*, *piles*, *fissure of the anus or rectum*, *sore nipples*, *phagedenic ulcers*, *aphthous ulceration of the mouth*, *sore throat*, *severe salivation*, and in *toothache*, in solution with ether. Applied to *nasal polypi*, it is stated to have produced a rapid disappearance of the abnormal growths. In the form of ointment, it will frequently prove effectual in curing *vaginal leucorrhæa*, being introduced into the vagina on lint or cotton, and allowed to remain there, changing it every 3, 4, or 5 hours. In solution or powder, in the form of spray passed upon the affected parts, it gradually overcomes *chronic mucous irritation or congestion*, and has been beneficially applied in *chronic nasal, faucial, pharyngeal and laryngeal mucous affections*. Dissolved in 3 parts of muci-lage, it has effected cures in *chronic granular conjunctivitis*, *corneal ulceration*, and other affections of the eye. It may be used in *ophthalmia neonatorum*, with granular conjunctiva (1 part in 10 of water); and in *purulent conjunctivitis*, with but little swelling and small quantity of secretion, use a wash of from 2 to 10 grains to 1 ounce of distilled water. In the early stage of *trachoma*, when there is slight roughness of the conjunctiva, the beginning of granulation, with injected and clouded upper part of the cornea, a glycerole (5 grs. to 1 fl̄ʒ) dropped into the eye in 2-drop doses will allay the gritty sensation. In advanced trachoma, with soft, pasty granulations, it may be used in connection with gallic or boric acids (*R* Boric acid ʒiij; tannic acid ʒi; *R* Gallic acid ʒi; tannic acid ʒiij). It is of little value to destroy *aural polypi*, and when used in *suppurative otitis media*, as it sometimes is, it is objectionable in that hardened masses, difficult of removal, are formed. Its solution in glycerin is a powerful styptic. It may be employed in the form of a wash, by adding 5 grains to a fluid ounce of water; or in ointment, 1 part of the acid to 10 or 15 of lard. It is a valuable remedy, the only disadvantage being its tendency to produce constipation, which may be

avoided by the addition of a small quantity of podophyllum resin, in cases where this resin is not contraindicated.

The glycerole of tannin is very efficient in *sores* occurring from the use of false teeth; and in *ingrowing toe-nail*, with fungous granulations, the pure acid is especially useful. It forms a good dressing for *burns*. Several cases of *cholera* in the collapsed stage have been cured by our physicians, by doses of 10 or 15 grains of tannic acid, repeated every 10 or 15 minutes, until the discharges ceased; and continuing it afterward at longer intervals, with other appropriate treatment. Tannic acid, as an internal astringent, sometimes leaves the tissues upon which it acts harsh and dry. Dr. Chausarel has proved that tannic acid is the best antidote against *poisonous fungi*, or *mushrooms*, etc.; 30 or 40 grains of tannic acid, dissolved in a pint and a half of water, may be taken in small glassful doses every 5 minutes; if too much time has not elapsed an emetic may be first administered. Tannic acid is one of the best antidotes against *poisoning by strychnine*, forming an insoluble tannate of strychnine; it may be given freely. Dose of tannic acid, from half a grain to 10 grains. Suppositories, consisting each of 12 or 15 grains of butter of cacao, and 3 to 5 grains of tannic acid, are valuable in some rectal and vaginal diseases, as *anal prolapsus*, *hemorrhoids*, *abrasion of the vaginal epithelium*, *leucorrhœa*, etc.

Specific Indications and Uses.—Relaxed states of the gastro-intestinal tract, with excessive secretions, and no fever or inflammation; soft, pasty or fungoid granulations; passive hemorrhages; leucorrhœa with vaginal relaxation.

ACIDUM TARTARICUM (U. S. P.)—TARTARIC ACID.

FORMULA: $H_2C_4H_4O_6$. MOLECULAR WEIGHT: 149.64.

SYNONYMS: *Dextro-tartaric acid*, *Dioxysuccinic acid*, *Sal essentiali tartari*.

"An organic acid usually prepared from argols"—(U. S. P.).

Source and History.—Scheele first prepared this acid in 1769. Retzius, in 1770, produced it in crystalline condition. Tartaric acid is a constituent of grape juice in the form of an acid tartrate of potassium, and is also contained in many other plants, as in the juice of the pineapple, tamarind, sorrel, mulberry, "sumach-bob," etc. The acid of commerce is produced almost exclusively from "crude tartar" or "argols," a refuse by-product in the manufacture of wines. Formerly the American market was chiefly supplied by European manufacturers, but at the present time nearly all of the acid consumed here is produced in the United States from argols shipped from European ports.

Preparation.—This acid is prepared somewhat similarly to citric acid, by forming tartrate of calcium and decomposing it by sulphuric acid; this is generally effected by adding an excess of carbonate of calcium to a solution of acid tartrate of potassium, which yields a precipitate of insoluble tartrate of calcium. The remaining salt in solution (neutral potassium tartrate), is then treated with calcium chloride, which decomposes it with the production of soluble potassium chloride and insoluble calcium tartrate, which latter product is then collected, thoroughly washed, and acted upon by sulphuric acid, which sets the tartaric acid free, and forms a precipitate of sulphate of calcium. To obtain the acid pure, it is evaporated, crystallized, redissolved in water, strained, and recrystallized three or four times. When prepared on an extensive scale, sulphate of calcium is substituted for chloride of calcium on account of the cheapness of the former. The colored crystals are treated with charcoal and recrystallized. The finest crystals are produced when there is a slight excess of sulphuric acid.

Description.—Tartaric acid occurs in "colorless, translucent, monoclinic prisms, or crystalline crusts, or a white powder, odorless, having a purely acid taste, and permanent in the air. Soluble at 15° C. (59° F.), in about 0.8 part of water, and in 2.5 parts of alcohol; in about 0.5 part of boiling water, and in about 0.2 part of boiling alcohol; also in 250 parts of ether; nearly insoluble in chloroform, benzol, or benzin. When heated for some time at 100° C. (212° F.), the powdered crystals do not suffer a sensible loss of weight. At 135° C. (275° F.), the acid melts. At higher temperatures it is gradually decomposed, emitting the odor of burning sugar, and is finally consumed without leaving

more than 0.05 per cent of ash. Tartaric acid has an acid reaction upon litmus paper"—(*U. S. P.*).

Its aqueous solution molds on exposure, yielding acetic and butyric acids. Fused with hydroxide of potassium, it decomposes into acetic and oxalic acids and water. When gently heated, the crystals of tartaric acid acquire electrical polarity equal to that of tourmaline. Tartaric acid possesses in a remarkable degree the property of turning the plane of polarized light to the right, which is increased by warming the substance, as well as by combination with bases. Nitric acid immediately decomposes it into oxalic and carbonic acids; chlorine does not decompose it. Tartaric acid gives rise to tartrates of two kinds, the neutral and acid tartrates; with caustic potash and ammonia it forms neutral salts, easily soluble, and acid salts not easily soluble. When heated with sulphuric acid they are readily charred. Tartaric acid may be reduced to succinic acid by saturating its concentrated aqueous solution with hydriodic acid, sealing in a strong glass tube, and heating it for 6 or 8 hours, not to exceed the temperature of 120° C. (248° F.). Tartaric acid may be known by its sour solution, which gives white precipitates with solutions of caustic lime, baryta, strontia, and acetate of lead, the precipitated tartrates being soluble in excess of acid. Ammonium chloride dissolves the precipitate produced by lime-water. Sulphate of calcium gives no precipitate; a solution of chloride of platinum causes a black precipitate of metallic platinum. Most of the commercial tartaric acid is in the form of a white, crystalline powder.

By the researches of M. Pasteur, the existence of four isomers of tartaric acid (dextro-tartaric) was established, all having the same formula, $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$, but differing principally in their behavior towards polarized light. These isomers are: (1) racemic, (2) lævo-tartaric, (3) meso-tartaric, and (4) meta-tartaric acids.

1. *Racemic acid* (*para-tartaric* or *uvic acid*), occurs in the mother liquors obtained in the making of cream of tartar. It is optically inactive, being a compound of equal amounts of dextro- and lævo-tartaric acids, and has been resolved into its constituents by preparing a supersaturated solution of its sodium-ammonium salt and dropping into the fluid a crystal of the sodium-ammonium salt of either the dextro- or the lævo-rotatory acid, whereby this form of salt will crystallize out while the other form remains in solution. Mineral acids will then liberate the respective free tartaric acids from these salts. Racemic acid is best obtained by heating ordinary tartaric acid with 0.1 part of water, to 175° C. (347° F.), whereby it is completely converted into meso-tartaric and racemic acids. It crystallizes more readily than tartaric acid, into efflorescent, triclinic prisms, containing 1 molecule of water of crystallization. Its acid potassium salt is by far more soluble than the salt of dextro-tartaric acid (cream of tartar); its calcium salt is distinguished by its being insoluble in acetic acid.

2. *Lævo-tartaric acid*, turns the plane of polarized light to the left, and has otherwise the general properties of the dextro-acid.

3. *Meso-tartaric acid*, is formed when dextro-tartaric acid is heated to 165° C. (329° F.), with about one-eighth its quantity of water, for about 2 hours. It is optically inactive and can not be resolved into dextro- and lævo-tartaric acids.

4. *Meta-tartaric acid*, is formed when dextro-tartaric acid is heated till it fuses, *i. e.*, to 130° C. (266° F.). It is also dextro-rotatory, but differs from ordinary tartaric acid mainly in its deliquescence and that of its salts.

Tests.—The *U. S. P.* directs the following tests for tartaric acid: "An aqueous solution (1 in 2) of the acid mixed with a strong solution (1 in 3) of potassium acetate yields a white, crystalline precipitate which is soluble in solutions of alkalis and in mineral acid, but insoluble in acetic acid. The aqueous solution (1 in 10) of the acid, acidulated with a few drops of hydrochloric acid, should remain unaffected by barium chloride T.S. (absence of sulphuric acid). Another portion of the aqueous solution (1 in 10) in which the free acid has been nearly, but not entirely, neutralized by ammonia, should not be affected by calcium sulphate T.S. (absence of and difference from oxalic and uvic acids). On supersaturating 10 Cc. of the aqueous solution (1 in 10) with ammonia water, no turbidity should be produced in the liquid by ammonium oxalate T.S. (absence of calcium), nor should the further addition of 1 drop of ammonium sulphide T.S. produce any dark coloration or precipitate (absence of iron, lead, copper, etc.). To neutralize

3.75 Gm. of tartaric acid should require 50 Cc. of potassium hydrate V.S. (each Cc. corresponding to 2 per cent of the pure acid), phenolphthalein being used as indicator"—(U. S. P.).

Action, Medical Uses, and Dosage.—Tartaric acid in large doses is an unsafe agent, causing gastro-intestinal inflammation and death. The symptoms in man from 1 ounce largely diluted, were intense, burning pain in the fauces and stomach, persistent vomiting, and death in nine days, the effects being those of a corrosive poison.

Tartaric acid is refrigerant, antiseptic, and antiscorbutic. It is used as a drink in *febrile* or *inflammatory diseases*, forming a cooling, refreshing, and agreeable acidulous draught. It is less costly than citric acid, and may be used instead of this acid to form an artificial lemonade. Tartaric acid enters into the composition of *Seidlitz*, as well as of *soda powders*. A colorless solution of sulphate of quinine has long been employed by physicians; it may be made by adding equal parts of tartaric acid and sulphate of quinine to as much water as may be desired. The dose of tartaric acid is from 10 to 30 grains dissolved in water or syrup.

Related Preparation.—ACIDUM TARTARICUM SACCHARATUM (N. F.), *Saccharated tartaric acid*. *Formulary number*, 8: "Tartaric acid (U. S. P.), in very fine powder, six hundred and seventy-five grammes (675 Gm.) [1 lb. av., 7 ozs., 354 grs.]; sugar, in very fine powder, three hundred and twenty-five grammes (325 Gm.) [11 ozs. av., 203 grs.]. Triturate the powders together until intimately mixed, and preserve the product in well-stoppered bottles.

"*Note.*—This saccharate, when dissolved in water with an equal weight of saccharated sodium bicarbonate (F. 341), will form a neutral solution, and it is introduced into the formulary for the convenient preparation of effervescent powders (F. 319). This saccharate contains 87.5 per cent of tartaric acid"—(Nat. Form.).

ACIDUM VALERIANICUM.—VALERIANIC ACID.

FORMULA: $\text{HC}_8\text{H}_{13}\text{O}_2$. MOLECULAR WEIGHT: 101.77.

SYNONYMS: *Valeric acid*, *Isopentioic acid*, *Isopropyl-acetic acid*, *Acidum valericum*.

Source and History.—Chevreul, in 1817, first obtained this acid from the oil of the dolphin (*Delphinus globiceps*), and named it *delphinic acid*. An identical acid was afterward found in the *Valeriana officinalis*, after which the name *delphinic acid* was changed to *valerianic acid*. Besides being found in *valerian*, it exists in *Sambucus nigra*, *Anthemis nobilis*, *Artemisia Absinthium*, *Angelica archangelica*, *Viburnum opulus*, and other plants. Oxidized organic material yields it. The pure acid from *valerian* plant is seldom used in medicine, but in its stead an acid, prepared by the oxidation of fusel oil (amylic alcohol), when acted upon by sulphuric acid and potassium bichromate, is employed. So violent is the reaction, and so disagreeable the odor, that few care to make *valerianic acid*.

Preparation.—The U. S. P. (1870) directed to take coarsely-powdered sodium valerianate, 8 troy ounces; sulphuric acid and water, of each a sufficiency. Three fluid ounces of the water are first added to the valerianate, and subsequently $3\frac{1}{2}$ troy ounces of the sulphuric acid, and all mixed thoroughly. After standing, an oily acid layer rises to the top, which must be removed and agitated with small quantities of sulphuric acid until its density is below 0.950. This is put into a retort, distilled almost to dryness, rejecting that distillate having a density above 0.940. The remainder is kept for use. The rejected distillate may be redistilled, yielding an acid sufficiently pure to use in preparing the valerianates.

Description.—Valerianic acid is a thin, colorless, inflammable, oily fluid, of an intensely disagreeable and offensive odor, and has an unpleasant, acid, sour, burning taste. It has a strong acid reaction. With alkalis it forms valerianates. With alcohol, in which it is freely soluble, it forms an almost odorless solution, but if water be brought into contact with it, it instantly regains its disagreeable odor. It is freely soluble in water, chloroform, ether, and concentrated acetic acid. With the volatile oils and carbon disulphide it forms turbid mixtures. Camphor and some resins are soluble in it. Most of its salts are permanent and odorless when dry, but added to water (in which most of them are soluble) they develop the rank odor of the acid.

Action and Medical Uses.—Experimentation upon animals showed Reissner that this acid was strongly irritant to the skin and membranes, and that it

coagulated milk, albumen, and the serum of the blood. Quickened and enfeebled respiratory and cardiac action were noticed, with marked debility and paralysis of the extremities, followed by spasm and death. If death were slow, the kidneys were found congested, the urine bloody and turbid, and the bowels inflamed; if death resulted quickly, the gastric interior was pallid. This acid is only used in medicine in combination with bases forming valerianates.

ACONITINA.—ACONITINE.

FORMULA: $C_{34}H_{47}NO_{11}$ (Freund and Beck). MOLECULAR WEIGHT: 643.55.

SYNONYMS: *Aconitia*, *Aconitinum*.

Preparation, History, and Chemical Composition.—Wright's process is as follows: Exhaust powdered aconite root with alcohol, in which has been dissolved 0.5 per cent of tartaric acid. Distill the alcohol to complete evaporation at a low heat or *in vacuo*. Dilute the extract so obtained with a like quantity of water, remove the oil and resin by filtration, add ether or petroleum naphtha to remove the remaining resin, and precipitate with excess of salt of tartar. Dissolve the precipitate in ether, mix again with petroleum naphtha and evaporate. This process will yield a crystalline aconitine, having, however, a small amount of adherent amorphous product, not wholly separated by the potassium carbonate. Other methods, in which sulphuric acid and ammonia water are chiefly employed, yield an amorphous product. The chemistry of aconite and aconitine has been the subject of much controversy. That the mineral acids produce the amorphous form, and that tartaric acid does not decompose aconitine, were first shown by Duquesnel, in 1872. Groves first obtained it in crystalline form. Wright (1875–1880) showed that aconitine could be resolved by heat or by saponification with an alkali into benzoic acid and *aconine* ($C_{28}H_{39}NO_{11}$), an amorphous body, identical with *acolyctine* and *napelline*, and having a bitter, non-acrid taste. Aconine dissolves freely in water, alcohol, and chloroform, but is nearly insoluble in ether. Wright assigned to aconitine the formula $C_{38}H_{48}NO_{12}$, and found its fusing point to be 183°C . (361.4°F). Subsequently Dunstan and Ince, in 1891, gave it the formula $C_{38}H_{48}NO_{12}$; fusing point 186.5°C . (367.7°F). In 1894 and 1895, Freund and Beck pronounced aconitine to be an acetyl-benzoyl derivative of aconine, establishing for the latter alkaloid the formula $C_{28}H_{39}NO_9$; hence, for the pure aconitine $C_{34}H_{47}NO_{11}$, having a fusing point at $197\text{--}198^{\circ} \text{C}$. ($386.6\text{--}388.4^{\circ} \text{F}$). The results obtained by Dr. Freund seem now to be generally adopted as correct. Commercial aconitine has repeatedly been shown to be of various degrees of strength, and is a mixture of the foregoing alkaloids, together with *pseudoaconitine* ($C_{38}H_{48}NO_{12}$) and *picroaconitine* ($C_{38}H_{48}NO_{10}$), the former being capable of conversion into *dimethyl-protocatechuic acid* (*veratric acid*) ($C_9H_9NO_4$) and *pseudoaconine* ($C_{27}H_{37}NO_9$). [For a recent investigation in this direction, see Dohme, *Proc. Am. Ph. A.*, 1895, p. 206].

Description.—The pure alkaloid has a slightly bitter, but acrid, taste, and dissolves easily in alcohol, ether, chloroform, and benzol. That made according to the *British Pharmacopœia*, is a white, amorphous body, sparingly soluble in cold, more readily in hot water, and still more freely in ether and alcohol, but it is almost insoluble in benzin. It produces protracted numbness, preceded by tingling, when rubbed on the hands or skin. Pseudoaconitine alone is often sold for crystalline aconitine. According to Dr. E. R. Squibb (*Ephemeris I.*, 135), no aconitine should be accepted of which $\frac{1}{16}$ grain dissolved in 1 fluid drachm of water, and held in the anterior portion of the mouth (first well rinsed) for 1 minute, which will not, within 15 minutes, produce a pronounced aconite sensation short of, but bordering on, numbness. Most of the commercial aconitine is now made by patented processes.

Action, Medical Uses, and Dosage.—The effects of this drug are those mentioned under aconite, though greatly intensified, as it is a much more powerful agent than the parent drug. The ointment or alcoholic solution, applied to the unbroken skin, produces tingling, prickling, and anæsthesia. Neither redness nor heat are observed, however, from such use. Upon broken skin, intense burning is felt, and when placed upon the ocular membranes violent irritation is pro-

duced. It should never be used as an internal agent, its effects being such that its employment, when the drug is pure, is too hazardous. Owing to the variability of the commercial product the dosage can not safely be regulated.

Dr. Turnbull introduced aconitine as an external agent in *neuralgia* and *rheumatism*, in the form of tincture or ointment. His ointment is composed of aconitine, 16 grains; olive oil, half a drachm; lard, an ounce. Mix. To be rubbed for several minutes over the affected part. The tincture is made by dissolving 8 grains of aconitine in 2 fluid ounces of alcohol. In using these preparations they should not be applied where the skin is broken or excoriated. Even as an external agent its use should be discouraged. When employed internally, as it has been by some physicians, the dose ranges from $\frac{1}{100}$ to $\frac{1}{50}$ grain; as a beginning dose not more than $\frac{1}{100}$ grain should be administered. We have known alarming symptoms to be produced by $\frac{1}{100}$ grain of aconitine.

ACONITUM (U. S. P.)—ACONITE.

The root and leaves of the *Aconitum napellus*, Linné. (*Aconitum vulgare*, De Candolle; *Aconitum variabile*, Hayne).

Nat. Ord.—Ranunculaceæ.

COMMON NAMES.—*Monkshood*, *Wolfsbane*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 5, 6, 7.

Botanical Source.—Aconite plant is a perennial herb, having a simple stem (usually growing from 2 to 4, sometimes 8 feet high), and bearing palmately-lobed leaves; those low on the stalk being from 5 to 7-cleft, those higher 3 to 5-cleft. Each of these lobes is, again, from 3 to 5-parted. They are alternate, petiolate (the lower ones having long foot-stalks), and are deeply divided, and vary from 2 to 4 inches in diameter. Each lobe is toothed in such a manner that each tooth terminates in a lance-linear point. The leaves are stiff and somewhat smooth and coriaceous, the under surface being light, while the face of the leaf is of a bright, shining, green color. The flowers are large, attractive, and of a dark-purple or violet-blue hue (sometimes white) and are borne in a terminal raceme, with occasional clusters below, in the axils of the leaf stalks. The upper sepal is helmet-shaped and pointed, and the lateral sepals hairy on the inner surface. The fruit consists of from 3 to 5 capsular pods, containing numerous angular, corrugated seeds.

Fig. 2.

Aconitum napellus.

Description.—ACONITUM (U. S. P.) *Aconite*.

ACONITI RADIX.—The root is prolonged into a conical tap-root, tuberous, and though smaller, has some resemblance to the common horse-radish root, for which it has been mistaken, and eaten with fatal consequences. At the top it seldom exceeds an inch in thickness, and is about 2 to 4 inches long. Externally, it is brown; internally white and fleshy. As found growing, there is usually a rhizome produced from a lateral bud from the tuber. At the extremity of this subterranean stem, another tuber, with a bud for the next year's plant, is developed. This second tuber, in the course of the year, develops a third tuber, so that when dug for commerce it is common to find at least two roots, connected by a short rhizome. Each root has several long, fleshy rootlets. The fresh root has a radish-like odor which is dissipated on drying. The dried root is thus described in the U. S. P.:

"From 10 to 20 Mm. ($\frac{3}{8}$ to $\frac{1}{2}$ inches) thick at the crown; conically contracted below; from 50 to 75 Mm. (2 to 3 inches) long, with scars or fragments of radicles; dark-brown externally, whitish internally; with a rather thick bark, the central

axis about seven-rayed; without odor; taste at first sweetish, soon becoming acrid, and producing a sensation of tingling and numbness, which lasts for some time"—(U. S. P.).

If of recent growth, it is whitish, internally, and compact, breaking with a short, clean fracture. If, however, the root be of the previous year's growth, it may be porous and of a dark-brown color within, and consequently of less value as a drug.

ACONITI FOLIA.—Aconite leaves are often intermixed with some of the flowers, as well as leaves and blossoms of other blue-flowered species of the family.

The leaves are smooth, coriaceous, somewhat rigid, glossy on the upper surface, having a sub-orbicular, or nearly cordate outline, which is deeply (3 to 5) cleft, producing long, narrow, cuneiform segments, deeply incised, and presenting lance-linear teeth. The taste is bitterish and acrid, and gives the well-known characteristic tingling sensation of aconite. They have but little, if any, odor.

History.—Aconite is abundant in the mountainous woodlands of various parts of Europe, especially in France, along the Pyrenees, and in the rocky heights in Germany and Austria, Denmark, and the Scandinavian peninsula, and is abundant in the Alps and the Himalayas, where, with other species, it is found at a height of from 10,000 to 16,000 feet (*Pharmacographia*). It is plentiful throughout Siberia, and is cultivated to some extent in gardens, both in the United States and Europe, for its floral beauty. It is said to have been naturalized in portions of the British isles.

Fig. 3.
Cross-section of an Aconite flower.

Aconite tubers and leaves are frequently of very poor quality, and with foreign admixture as found in market, having been gathered without regard to season, species, or quality, by the poor peasants while engaged in watching the grazing herds. The shrivelled and decaying growth of the previous year is, as compared with the recent growth, relatively feeble. The aconites were well known to the ancient Greeks, Romans, and Chinese. It provided certain native tribes of the East with an active arrow poison. The root should be collected in winter or early spring; the leaves just before the blossoming period, or when the plant has but partially bloomed. The virtues of aconite remain intact upon drying, the whole plant being acrid and fully yielding its medicinal properties to alcohol. Various other plant species are present as admixtures, and especially, according to Holmes (*Pharm. Jour.*, 1877), are substituted the roots of the *Imperatoria Ostruthium*, Linné (European masterwort). As the latter tuber is aromatic, its detection is not difficult, though the roots somewhat resemble the aconite tubers. Good aconite is usually known by its characteristic benumbing taste. Aconite was introduced into modern medicine by Baron Störck, of Vienna, about 1762.

Chemical Composition.—Besides mannite, cane sugar, glucose, resin, and fats, aconite root contains aconitic acid ($H_3C_6H_5O_6$), usually combined with calcium in the form of calcium aconitate. This acid is also present in a number of other plants. It occurs in plate-like or warty crystals, soluble in alcohol, ether, and water. The most important constituent, however, is the alkaloid *aconitine* (*napaonitine*, *benzoyl-acetyl-aconine*) ($C_{33}H_{45}NO_{12}$, Wright; $C_{33}H_{45}NO_{12}$, Dunstan and Ince, 1891; $C_{34}H_{47}NO_{11}$, Freund and Beck, 1894), for a description of which and other constituents of aconitum usually present in the commercial alkaloid, see *Aconitine*. Aconite leaves contain, besides aconitine, gum, albumen, sugar, tannin, aconitic acid, an amorphous alkaloid, bitter to the taste, called *napelline*, which Hübschmann found to be identical with a substance previously isolated by him from another species of aconite (*Aconitum Lycoctonum*, Linné), and named *acolytine*, but considered by C. R. A. Wright to be a decomposition product of *aconitine*. The tubers also contain a small amount of *napelline*.

Action and Toxicology.—Aconite is an energetic, acro-narcotic poison in improper doses, occasioning symptoms of gastric irritation, with great depression of nervous energy and brain. The usual effects of an improper dose of either the tincture or powder, are a prickling, or slight thrilling in the mouth and

limbs, accompanied with a benumbing sensation, but without, as a rule, coma or convulsions. Several of the following symptoms will soon manifest themselves: Vomiting, perhaps great thirst, sometimes violent purging with painful spasms of the stomach and bowels, sense of great exhaustion, pale face, impaired vision, scarcely perceptible pulse, coldness of feet and legs, and coma, or delirium; and, from paralysis of the respiratory muscles, death follows. These symptoms may vary in different cases, though several of them will always be present. Gastritis and enteritis, with pulmonary and cerebral congestion, are exhibited upon a post-mortem examination.

Locally, aconite and its alkaloid produce a prickling sensation and numbness, followed by an impairment of the sensory nerves, resulting in anæsthesia of the part. Both are very irritating to the Schneiderian membrane and conjunctiva. Aconitine produces the effects of aconite, though in a much more exalted degree. Taken internally, in small amounts, aconite occasions a tingling, prickling sensation of the buccal cavity, fauces, and tongue, followed by more or less numbness. If not too large a quantity has been swallowed, these effects are overcome by a swallow of vinegar (Scudder). The tincture, in non-lethal doses, gives rise to a sense of gastric warmth and a general glow of the surface. Perspiration may be induced and the renal secretions augmented. Pyrexia is reduced when the pulse is frequent and feeble, if the drug be administered in minute doses.

In maximum medicinal doses, it causes gastric heat, which extends throughout the general system, and occasionally the prickling sensations will be experienced, with, perhaps, benumbing feelings; or, these may pass over the whole system, with dizziness, more or less pain in the head, acute pains, excessive depression of the vital forces, with feeble circulation and respiration. Aconitum should never be given in sufficient quantity to produce these effects. A drop of a solution of aconitum in the eye causes the pupil to contract. Larger amounts induce toxic symptoms, the principal of which are increase of tingling and numbness, or thrilling of the mouth and extremities, excessive perspiration rapidly lowering the body temperature, pupillary dilatation, dimness of sight, loss of hearing and the sense of touch, and diminished action of the sensory filaments supplying the skin. Muscular weakness is marked; trembling, and occasionally convulsions may ensue. Excessive depression comes on, and the power of standing is early lost. The feet and legs become cold, the face pale, and the patient has a tendency to faint. There may be violent burning in the stomach, with great thirst and dysphagia, and vomiting and diarrhœa may occur. The pulse is weak, rapid, and almost imperceptible; acute, lancinating pain may be felt, and more or less delirium may result, though as a rule the intellect remains unimpaired. The manner in which aconite affects the nervous system is not yet definitely known. That it is a heart paralyzer, seems to be an accepted fact. Death may result from syncope, though usually it occurs from respiratory paralysis. The action of a lethal dose is rapid—toxic symptoms showing themselves within a few moments. The treatment consists in keeping the patient in a recumbent position, with the feet slightly elevated. External heat should be applied, and stimulants (as brandy, ammonia, ether) administered. It is stated that digitalin previously administered, to animals, wholly prevented the toxic action of aconitine (Fothergill); hence digitalis is recommended to antidote aconite poisoning. Tannin (astringents) is said, also, to be an efficient antidote. Inhalations of nitrite of amyl were resorted to in one case with good results. Strychnine, atropine, or strophanthus may be cautiously administered. In no case allow the patient to arise from the recumbent posture, lest death suddenly take place from syncope. The stomach should, of course, be promptly evacuated with the stomach-pump, or emetics and artificial respiration resorted to, if necessary, for the prevention of respiratory paralysis.

Medical Action, Uses, and Dosage.—Therapeutically, aconite is a special sedative, and, according to Prof. J. M. Scudder, is the remedy when there is difficulty in the capillary circulation, a dilatation and want of tone in these vessels, as it moderates the force and frequency of the heart's action, increasing the power of the heart and the tone of the blood-vessels, and hence is advantageous in asthenia and extreme debility; it also has a tendency to lessen pain and nervous irritation. He considered it the remedy in cases where there is a frequent but free

circulation; where there is an active capillary circulation; and where there is a marked enfeeblement of the circulation, manifested by a frequent, small pulse, a hard and wiry pulse, a frequent, open, and easily compressed pulse, a rebounding pulse, or an irregular pulse. In *congestion*, especially of the nerve-centers, to relieve coma, and in *diabetes insipidus*, he associated its administration with belladonna; with the bitter tonics in *phosphuria* and *oxaluria*; and with the mineral acids in *night-sweats*. While it acts upon the excretory organs, increasing excretion, yet it controls excessive activity of these organs, whether of the skin, bowels, or kidneys, and hence its value in *summer complaint* of children (*Ec. Med. Jour.*, 1868, p. 430).

With the *small, frequent* pulse, whether corded or easily compressed, aconite is a remedy of wide applicability in asthenic or adynamic states. Our old school competitors assert that aconite should never be given only in sthenic conditions, but their conclusions are evidently based upon the use of too large doses. Given in the minute dose, as employed by our physicians, it tends toward a restoration of normal action. With the characteristic pulse, its action in *fevers* is to reduce the temperature, generally in the proportion in which it controls the frequency of the heart-beat; if, on the other hand, the temperature be subnormal, as in the cold stage of fevers, *congestive chill*, or in *Asiatic cholera*, the minute dose increases the warmth of the body, giving volume and freedom to the pulse, and tending toward a normal circulation.

"If we note its action in active inflammation, we notice that it lessens determination of blood, quiets the irritation, checks the rapid circulation in the capillaries where it is too active, and increases the circulation where it is sluggish. If, as we think, it acts upon and through the ganglionic system of nerves, we can account for all this by saying that it gives *right* innervation. I have been in the habit of saying that aconite was a stimulant to the heart, arteries, and capillaries, because whilst it lessened the frequency, it increased the power of the apparatus engaged in the circulation" (Scudder, *Dis. of Child.*, 42, 43). It must be remembered that our term sedative differs somewhat from that accepted by other schools. A remedy, such as aconite, which in minute doses will stimulate the vascular system to normal activity, and thereby reduce febrile states by correcting innervation, comes under our class of "special sedatives." As a special sedative, it is useful in all *asthenic febrile* and *inflammatory diseases*, and, indeed, in all affections in which there is an increase of nervous, vascular, or muscular action with determination of blood to the parts. In *scarlatina*, *inflammatory fever*, *acute rheumatism*, *peritonitis*, *gastritis*, and many other acute disorders, it has been used with the most decided advantage. Added to *cimicifuga*, it greatly increases the curative influence of this agent in *acute rheumatism*, and more especially where there is a tendency to muscular spasm. "In cases of pure *inflammatory rheumatism*, independent of any organic lesion, and with no septic processes going on in the blood, aconite is an absolute specific" (Locke). By its beneficial action upon the sensory nerves, it is a remedy of marked value in various forms of *neuralgia*. In *facial neuralgia*, not due to carious teeth, it may be aided by piper methysticum (Webster), and is especially applicable when febrile phenomena are present. In *rectal neuralgia*, it may be used with *æsculus glabra*, *æsculus hippocastanum*, *collinsonia*, or *hamamelis*, as indicated; in *visceral neuralgia*, with *æsculus glabra*. Its action in neuralgias is not pronounced in most instances when administered alone, but it greatly aids the other indicated remedies, particularly where fever is a concomitant condition. *Peridental inflammation* is allayed by it.

In *simple fevers*, aconite aids diagnosis. "If in twelve hours' treatment with aconite the patient is not well, or markedly improved, he has more than a case of simple fever" (Locke). In *typhoid fever*, it cannot arrest the disease, though it may be used, if clearly indicated, which we believe is rarely; *baptisia* is a much better remedy here. *Rheumatic* and *intermittent fevers* are benefited by it, especially when slight chilly sensations are repeatedly experienced. *Gastric fever*, with yellow-coated tongue, bad taste, and diarrhoea of undigested aliment, is controlled with aconite in small doses. Its action is marked in many *inflammatory skin diseases*. In *erysipelas*, when high fever is present, never omit aconite (Locke). In *brain* and *meningeal disorders*, it is frequently of marked advantage. Add to

the characteristic pulse a hyperemic state of the superficial cerebral and meningeal vessels, and your case is one for aconite. If there be great excitation, gelsemium will aid its action; if congestion, belladonna. *Insomnia*, from nervous erethism, points to aconite for its relief. Such a state, bordering upon convulsions, sometimes depends upon *teething* and *gastro-intestinal diseases*. *Mental perturbation*, with fever, and a fear of impending disaster, with melancholia, is said to be relieved by aconite. Webster pronounces it "the pulsatilla of the febrile state."

By its control over the sympathetic nervous system, and its influence on the circulation and temperature, aconite becomes one of the most important remedies in the treatment of respiratory lesions. If the temperature is high, it reduces it; if it be abnormally low, it raises it to its normal standard. It is the remedy for all asthenic inflammatory and febrile conditions, especially in their earlier manifestations. It is the remedy for hyperemia; it is the remedy for loss of tone in the capillary structures resulting in inflammation. Loss of tone in a part causes capillary stasis, which, if allowed to go on, results in congestion, and, continuing, ends in inflammation. Here aconite controls the circulation, allays the irritation, lowers the temperature, and re-establishes the secretions. It acts as a gentle stimulant to the sympathetic system, consequently it has a good influence over irritation and inflammation in the parts supplied by it. Aconite is the remedy for irritation of the mucous surfaces. *Acute catarrh*, nasal and faucial, *acute pharyngitis*, and *ulcerated tonsils*, with elevated temperature, yield to aconite. It is the first remedy to be thought of in *tonsillitis*, *spasmodic* and *mucous croup*, and it is not without value in the pseudo-membranous form of croup. It may be used internally and locally. In spasmodic croup it allays the spasm, and the dyspnoea is quickly relieved. In tonsillitis it materially lessens the duration of the disease. It may be used early by spray, and given internally in small doses. Associated with gelsemium, it is of value in a large percentage of cases of "*la grippe*." In cases of *acute coryza*, it controls the febrile phenomena. In *pneumonia*, catarrhal or fibrinous, it is of signal value in the earlier stage to control the inflammatory process. It is good, though of less value, in the latter stage of the same malady, when bryonia is to be preferred. Its use in *acute bronchitis* and *laryngitis* gives good results. In *pleurisy*, it should be associated with bryonia in the earlier stage, with sharp pain, marked chill and high temperature, and the use of the latter agent should be continued to remove the effusions after the acute pains have subsided. It is one of the best agents to prevent *acute catarrhal pneumonitis*, as a complication of *measles*, and one of the best to control it in case it does supervene. The remedy should be administered in *phthisis*, to regulate the temperature, and is very valuable when new portions of the lung tissue are being invaded by the inflammatory process. It is said to give relief in *asthma*, with high temperature. Give the drug in small doses, frequently repeated, in acute disease; 3 or 4 times a day in chronic conditions.

No remedies surpass aconite and belladonna in the *exanthematous diseases*, and very frequently no other remedy than aconite will be indicated in *scarlatina* and *measles*. Here the hot, dry skin, with vascular excitation, calls for the drug, the temperature falling as soon as the eruption appears, which aconite aids in bringing out. Recent *amenorrhœa*, due to cold, is amenable to aconite if the circulation and temperature be increased. *Disorders of the menopause*, with alternate chills and flushes of heat, "with rush of blood to the head," cardiac palpitation, dyspnoea, gastric fullness, and sense of distension in the bladder, with frequent attempts to pass urine, are relieved by the usual dose of aconite every half hour (Locke). In *uterine hemorrhage*, as *menorrhagia*, with hot, dry face and excited circulation, aconite will relieve. In *cardiac diseases*, it has been employed with good results when there is *palpitation*, depending upon irritation; and for *heart spasm*, with a feeling of suffocation and as if the heart's action would cease, it is a prompt remedy.

Aconite is one of the first remedies for *gastro-intestinal diseases*, and especially the bowel troubles of children. All such disorders resulting from cold, or with inflammation, demand aconite as a part of the treatment. In *aphthous conditions*, with fever, associate it with phytolacca. It relieves *gastric irritation*, and may be associated with amygdalus, rhus, and ipecac. *Diarrhœa*, *cholera infantum*, *cholera*

morbus and *acute gastro-intestinal irritation*, usually yield to aconite and ipecac; while in *dysentery*, aconite, associated with ipecac and magnesium sulphate, is very prompt in controlling the disease. It is often indicated in the *diarrhoea of teething*.

A *hyperemic, oedematous conjunctiva*, with a feeling of burning and dryness, are the indications for its use locally and internally in inflammatory affections of the eye and its appendages. It shortens the inflammatory stage and allays pain in *acute catarrh of the middle ear*, though suppuration can not always be averted. The same result is obtained by its internal and external use in *mastoid disease*. Locally, aconite has been used in painful and neuralgic states, but is not much employed in this manner by our physicians. The usual prescription is: R Specific aconite, grt. ij to v; aqua, fl̄ iv. Mix. Sig. Dose, a teaspoonful every $\frac{1}{2}$ to 1 hour.

Dose: Tincture of aconite, 1 to 3 drops; extract of aconite, 1 to 2 grains; fluid extract of aconite, $\frac{1}{2}$ to 1 drop; specific aconite $\frac{1}{16}$ to $\frac{1}{2}$ drop. The larger doses should seldom be employed.

Specific Indications and Uses.—The *small and frequent pulse*, whether corded or compressible, is the direct indication; asthenic febrile state, with or without restlessness; chilly sensations; skin hot and dry, with small, frequent pulse; irritation of mucous membranes, with vascular excitation and determination of blood; hyperemia; tonsillitis and laryngitis, early stage; simple colitis.

Related Drugs and Species.—*Aconitum Lycocotum*, Linné. This plant yielded Hübschmann two alkaloids, *acolytine* (previously called by him *napelline*) in powdered form, and *lycotoxine* in crystalline needles. According to Flückiger, it is identical with neither aconitine nor pseudaconitine. Wright regards *lycotoxine* as identical with aconine, and *acolytine* with *pseudaconitine*. Dragendorff and Spohn, on the contrary, state the constituents of this plant to be *lycotoxine* ($C_{27}H_{34}N_2O_8 \cdot 2H_2O$), and *mycoctone* ($C_{27}H_{32}N_2O_8 \cdot 5H_2O$), the former of which, when boiled with water under pressure, splits into a volatile acid and *lycotoxonic acid* ($C_{17}H_{18}N_2O_7$), and an alkaloid soluble in ether, *lycotoxine*, and a second one, probably the *acolytine* of Hübschmann, soluble in chloroform. Hübschmann's *napelline* is regarded by Mandel as a mixture of aconine and aconitine in variable amounts. The status of the constituents of the several aconites does not seem as yet to be well understood.

BISHMA, or BIKHMA.—*Wakhma*. This variety is furnished by the *Aconitum palmatum*, Don. The tubers are very bitter, but non-acrid. They contain a non-toxic, bitter alkaloid. *Wakhma* is reputed tonic.

JAPANESE AND CHINESE ACONITE.—This drug consists of the tubers of several species of aconite variously preserved, sometimes, it is said, in child's or cow's urine, or in vinegar, or dried and salted. They are poisonous in varying degree; those of the *Aconitum Fischeri*, Reichenbach, being regarded as the most virulent. *Aconitum Chinense*, Siebold, and *Aconitum Japonicum*, Thunberg, as well as other species, amounting to seven altogether, are said to furnish this kind of aconite. An extremely poisonous principle, *japaconitine* ($C_{26}H_{32}N_2O_{11}$), has been isolated from Japanese aconite-tubers. It splits into benzoic acid and *japaconine*, when saponified (see *Aconitum Fischeri*).

ATIS, or ATIVISH.—*Atees, Utees*, etc. The tuberous roots of the *Aconitum heterophyllum*, Wallich, a species growing in the Himalayan country, constitute the *atis* of East Indian medicine. It is employed in its native country as a bitter tonic and antiperiodic, and is used as a vegetable (G. Watt). *Atisine*, discovered by Broughton, is the active constituent, and is a non-toxic, intensely bitter alkaloid. Broughton gave it the formula $C_{26}H_{32}N_2O_8$; Wright (1878) suggests $C_{22}H_{28}NO_2$ as being more nearly correct. Wacowitz (1879) found besides *atisine*, probably another amorphous alkaloid, sugar, mucilage, pectin, aconitic acid, starch, and a soft fat, which he thought to be a mixture of oleic, stearic and palmitic glycerides, and an acid resembling tannic acid. Pure *atisine* is white, amorphous, and exists only in minute quantities in the drug (Dymock, *Mat. Med. of Western India*).

BISH, BIS, BIKH, BIKLI, or NEPAUL ACONITE.—This variety is chiefly made up of the tubers of *Aconitum ferox*, Wallich, though *Aconitum napellus*, *Aconitum palmatum*, and other species probably contribute a portion. This variety is intensely acrid and poisonous. Its chief active constituent is the extremely poisonous *pseudaconitine* [*seraconitine*] ($C_{28}H_{36}NO_{12}$); and has also been termed, by Ludwig, *acraconitine*; by Wiggers, *napelline*; and by Flückiger, *nepaline*. F. Mandelin (*Arch. der Pharm.*, 1885) believes aconitine and pseudaconitine pharmacologically the same, and regards them as the strongest of known poisons. He also regards *japaconitine*, *aconitine*, and *benzoylaconitine*, as identical. *Pseudaconitine* ($C_{28}H_{36}NO_{12} + H_2O$), a new base formed by the saponification of *pseudaconitine*, and *aconine* ($C_{26}H_{32}NO_{11}$), one of the saponification products of aconitine, are regarded by the same investigator as either identical or homologous, and both poisonous, though less so than aconitine and pseudaconitine. Mandelin also believes that the difference in the poisonous effects of *Aconitum ferox* and *Aconitum napellus* depends wholly upon the relative amount of aconitine present in the two plants, and not upon any difference in virulence of the active principles of either. (See Dymock, *Mat. Med. of Western India*). Dymock states that Hindu authors mention "eighteen kinds of *Bish*, or poison," ten of which are too poisonous for medicinal use; also, that the word *bish* appears to have been applied "to any very poisonous root."

ACONITUM FISCHERI.—AMERICAN ACONITE.

The tuberous roots of *Aconitum Fischeri*, Reichenbach.

Nat. Ord.—Ranunculaceæ.

COMMON NAME.—*American aconite*.

ILLUSTRATION.—Lloyd's *Drugs and Medicines of North America*, Pl. xvii.

Botanical Source and History.—Though said to be the most active and poisonous of the species furnishing Japanese aconite root (Geerts, 1880), on account of its abundance in America and its likelihood of some day being the source of aconite for use in this country, we have taken the liberty to name this plant the *American aconite*.

Aconitum Fischeri, Reichenbach, is found in the Rocky Mountain region of the United States; also in other sections of the world. The plant is particularly mentioned here on account of the fact that its chemical properties are similar to those of aconite, and Prof. J. U. Lloyd, who has made an exhaustive study of the plant, prophesies that it may, at some future date, be an important source of aconite. In view of this fact, we extract from *Drugs and Medicines of North America*, by J. U. and C. G. Lloyd, a full botanical description of the plant: "This plant is quite common along the banks of streams in the mountains of the Western States. It is generally found near the tops of mountains and in mossy and boggy places. It usually grows near the water or in it, but never where the water is not fresh. It grows at an altitude of from 7,000 to 11,000 feet above sea level. The stem is erect and about 3 or 4 feet high, although in some favored situations it attains a height of 10 feet. The stem is smooth, except on the upper flowering portion, which is covered with a short pubescence. The leaves are orbicular in outline, and deeply three to five-lobed; the segments are acute, and coarsely and sharply-toothed. The leaf stalks are 2 to 6 inches long. The flowers appear in August or September, and are borne in a terminal loose raceme. They have the usual odd aconite shape, and can be recognized at once. They are usually of a deep-blue color, but vary to nearly white in some instances. Sometimes plants are found with bronzed flowers" (*Drugs and Medicines of North America*). It is an extremely variable plant, having been found in several forms.

Description.—The root of *Aconitum Fischeri* is described by the authors of *Drugs and Medicines of North America* as follows: "Our engraving (Fig. 5) represents the average size of the roots obtained by us. It will be observed that they are cylindrical and taper at the lower extremity. They are, as a rule, of greatest diameter about one-fourth the distance below the top, approaching, by a graceful curve, the constriction that separates the stalk from the root. The parent root produces each season a small tuberous root (sometimes more) at the base of the stalk, which develops and increases during the season until it is of full size; then the stalk dies, the mother root shrinks and decays, the young root forms a terminal bud in anticipation of the coming season, and also begins to send out the new root. Our engraving exhibits these several phases, the old, contorted, shriveled root being upon the right; the succulent, plump, young root, fully developed, in the

Fig. 4.

Aconitum Fischeri.

Fig. 5.

Root of *Aconitum Fischeri*.

center, and with its terminal bud; the new root for next season upon the left"—(*Drugs and Medicines of North America*). The root closely resembles the aconite root of commerce, develops in the same manner, is bitter to the taste, and has the peculiar benumbing effect upon the tongue which is possessed by true aconite.

Chemical Composition.—Prof. F. B. Power, at the request of Prof. J. U. Lloyd, has investigated the chemical properties of this plant, though owing to the lack of material at the time was unable to state definitely what the constituents were. He established conclusively, however, that the drug contained an alkaloid or alkaloids. Prof. Lloyd states, basing his views on the physiological investigations of Prof. Roberts Bartholow, undertaken at Prof. Lloyd's request, that the drug undoubtedly contains *aconitine*, associated with other proximate principles (see *Drugs and Medicines of North America*, p. 228). Paul and Kingzett have obtained from it an alkaloid, which has been named *japaconitine* ($C_{28}H_{48}N_2O_{11}$), a principle said by F. Mandelin (*Arch. der Pharm.*, 1885) to be identical with *benzoylaconine*. It has a close resemblance to Wright's *aconitine*. By saponification, it is resolved into *japaconine* ($C_{27}H_{41}NO_{10}$) and benzoic acid.

Action and Medical Uses.—American aconite has not been used to any extent in medicine, but in view of the fact that its constituents are probably similar to those of aconite, the drug should be studied to determine its action and therapeutical value.

Related Species.—*Aconitum uncinatum*, Linné, and *Aconitum reclinatum*, Gray, are also found in the Western States, but are unimportant. The last has not been chemically examined, and is probably inert; the former has proved to be practically inert as a medicine. V. Coblenz, at the request of Prof. Lloyd, examined it and found in it a glucosid, and a bitter, non-crystalline body of an alkaloidal character. Climate probably modifies the action of the aconites, as this species, in India, is poisonous and furnishes a portion of *Bish*.

ACTÆA ALBA.—WHITE COHOSH.

The rhizome and rootlets of the *Actæa alba*, Bigelow.

Nat. Ord.—Ranunculaceæ.

COMMON NAMES.—*White cohosh*, *White baneberry*, *Necklace weed*, *White beads*.

ILLUSTRATION.—*Drugs and Medicines of North America*, by J. U. and C. G. Lloyd, Pl. xviii.

Botanical Source.—*Actæa alba* is a perennial herb, having an erect stem about 2 feet high, bearing two large tri-ternate leaves, the leaflets of which are nearly oval, acute, serrate, and somewhat lobed. The flowers, which are handsome, showy, and white, are borne on a short, compact, oblong raceme with pedicles as large as the general peduncle. The petals are truncate at the apex, equalling the stamens. The fruit is a berry about the size of a cherry-pit, of an ivory white color, with an occasional tinge of red at the apex. These berries range from about 10 to 20 in number.

Fruit of *Actæa alba*.

Description.—The rhizome, which grows just beneath the surface of the soil, is about an eighth of an inch thick, fleshy, knotted, and has many fibrous rootlets. It weighs from 1 to 2 ounces when green. Where the stem joins the rhizome there is an enlargement which is often nearly an inch in thickness. Several offshoots, from 1 to 4 inches long, are given off from the main root. When mature the rhizome is usually decayed at one end and growing at the other. The young rhizome is sweetish, but less so than the mature rhizome which, however, is not so acrid as the former, having but a very faint acidity. The sweet taste is persistent, that of the younger having been compared to that of glycyrrhizin (Lloyd, *Drugs and Medicines of North America*). The dried is darker than the fresh root, shrunken, very hard, and has a sweet taste. The drug loses three-fourths of its weight in drying.

History and Constituents.—The cohoshes have received their name from the aborigines, who employed them as medicines. According to Barton they used

them for rheumatism, but depended more upon their topical than their internal action. They also employed them as emmenagogues and parturients. *Actæa alba* grows in the rich mold of rocky forests and hillsides throughout the Union, east of the Mississippi. Though pretty evenly distributed, it is nowhere an abundant plant. It blooms in May, about a week later than the red cohosh, and matures its fruit in July and August, several weeks later than the latter. It is frequently found as an adulterant among commercial lots of *cimicifuga*, but is not considered objectionable, as it undoubtedly possesses properties similar to those of black cohosh.

William Dillmore (1874) found the plant to contain albumen, sugar, starch, gum, and extractive, but neither tannic nor gallic acids. (The *A. spicata* is said to contain tannin). Two resins were also obtained, one soluble and the other insoluble in ether. Both, however, were dissolved by alkalies. The aqueous liquid, after precipitation of the resins from alcoholic solution, behaved like a solution of saponin. Prof. J. U. Lloyd (*Drugs and Medicines of North America*), obtained a resin exactly like the purified resin of black cohosh, which was neither acrid nor bitter, differing from Dillmore's resin, which was probably obtained from a drug mixed with spurious roots. Lloyd also obtained a tincture having a pure, sweet taste, without either acidity or bitterness. Chemically, as well as in other ways, this drug differs but little from *cimicifuga*, but owing to its scarcity as compared with the latter, it will probably never take its place as a medicine.

Action, Medical Uses, and Dosage.—White cohosh is an active agent, and in large doses will produce violent emeto-catharsis. Grave irritation and gastrointestinal inflammation have resulted from over-doses of the drug. It has been variously classed as alterative, emmenagogue, parturient, narcotic, purgative, and nerve stimulant. It specially acts upon the female reproductive organs, and favors waste and nutrition. The conditions in which it is useful are those of atony, and especially of nervous impairment. *Atonic digestive derangements*, with a low state of the nervous system, and *chronic constipation*, are cases for this drug. Its most decisive action, however, is in the disorders of the female organs. It is reputed a good *partus preparator*, and Dr. W. Fulton (see *Specific Medication*), accords it a first place in *puerperal after-pains*, and suggests its employment in *uterine congestion* and *neuralgia*. We would add here that it should be selected in debilitated states. It should be thought of in *menstrual irregularities* and other wrongs, as *amenorrhœa*, *menorrhagia*, and *dysmenorrhœa*. Those *ovarian affections*, attended with an unpleasant feeling and extreme sensibility to external touch or pressure, are asserted to be improved by its employment. Added to these may be headache, delirium, insomnia, and melancholia. When spasmodic diseases are due to menstrual wrongs—*chorea*, *epilepsy*, *hysteria*, and other convulsive attacks—the remedy is said to be curative. In *leucorrhœa* and *uterine prolapse* it should be used both locally and internally. In general its field of action is quite similar to that of *cimicifuga*. A peculiar pinkish hue of the part freely supplied by blood, usually associated with menstrual wrongs, is, according to Prof. Scudder (*Specific Diagnosis*), an indication for this drug, as well as for *pulsatilla* and *helonias*.

Dose: Decoction so made as to represent about 30 grains of the root, at one dose. Specific actæa, 1 to 20 drops. For its specific application the following is preferred: R Spec. actæa gtt. xx.; aqua f̄ijiv. Mix. Dose, a teaspoonful every 1 to 3 hours.

Specific Indications and Uses.—Atony of the nervous system associated with reproductive wrongs, headache, delirium, insomnia, melancholia, and convulsions; uneasy sensations in, and marked sensibility to the touch, or upon pressure, in the ovarian region; pinkish hue of the parts freely supplied by blood. Atonic states only.

Related Species.—*Actæa spicata*, Linné. *Baneberry*, *Herb Christopher*. Elevated parts of Europe, Caucasus, and Siberia. Grows to a height of 3 or 4 feet, having bi- or tri-ternate leaves, an ovoid raceme of white flowers, and glossy-black, juicy berries. The rhizome is blackish-brown, and when fresh has a disagreeable, bitter, acrimonious taste, followed by a sweet after-taste. The odor is nauseous, but when dried the root is nearly odorless. It gives its properties to water and alcohol. The berries are poisonous, causing mental hallucination,

Fig. 7.

Fruit of *Actæa spicata*,
var. *rubra*.

gastric irritation, and even death. The green root is violently purgative, resembling black hellebore, but less so when dried, and has emmenagogue properties. A decoction used locally, destroys lice, fleas, and the itch insect. Hens and ducks are killed by the berries, but herbivorous animals eat the plant with impunity. It is sometimes found as an adulterant of black hellebore.

Prof. Scudder (*Specific Medication*, 59), suggested its use in small doses (R. Tr. *actæa spicata* gtt. ij, aqua fl̄ iv. Mix. Dose, a teaspoonful, in diarrhœa, dysentery, some forms of colic, and urinary diseases with teneasmic passages of urine.

Actæa spicata, Linné, var. *rubra*, Aiton. *Red cohosh*, *Red baneberry*. This species inhabits the United States east of the Mississippi river, from Canada southward. It is almost identical in appearance with the *Actæa alba*, and they can hardly be distinguished from each other unless they are in fruit, though the latter flowers a week or so later than the red cohosh. The fruit of this variety (for it is only considered by botanists as a variety of the European species, *Actæa spicata*), is a glossy, cherry-red berry, of which the plant bears from 20 to 24. They ripen in early July. It was employed by the Indians under the name of red cohosh. It probably possesses similar properties to those of cimicifuga and the other actæas. *Actæa spicata*, var. *arguta*, Western United States, is another variety.

ADANSONIA.—BAOBAB.

The bark of *Adansonia digitata*, Linné.

Nat. Ord.—Malvaceæ.

COMMON NAMES.—*Baobab*, *Monkey-bread tree*, *Sour-gourd tree*, *Cream-of-tartar tree*.

ILLUSTRATIONS.—*Bot. Mag.*, Pl. 2791 and 2792.

Botanical Source and History.—*Adansonia digitata* is a large tree of the western coast of Africa and Egypt, sometimes attaining huge dimensions, being often 25 feet in diameter, although the height is not nearly so great in proportion. It was formerly supposed to attain a great age, and Adanson, a French botanist, in whose honor the tree was named, estimated a tree on the islands of Cape de Verd to be over 5,000 years old, a point disputed by Bentham, who asserts that *A. digitata* is of rapid growth and comparatively short-lived. It is the baobab tree of travelers, and also known as monkey-bread, cream of tartar tree, and sour-gourd tree. The local name is *Gowik Chentz* or *Churee Chentz*.

The leaves are digitate, and consist of five acute elliptical leaflets, resembling the leaves of our common buckeye. The flowers are very large and suspended on long peduncles; the calyx not having the peculiar involucre at its base which characterizes many genera of the Malvaceæ. The style is long, exserted from the staminal column, and bears a 10-rayed stigma. The fruit, which is nearly a foot long, is divided into 10 cells filled with an agreeably acid pulp in which the seed are imbedded.

The baobab tree belongs to the section Bombaceæ, of the natural order Malvaceæ, by De Candolle considered sufficiently distinct to form a separate natural order, which differs from Malvæ (the typical form of Malvaceæ) in having the calyx imbricated in the bud, and the stamiferous tube divided into five bundles at the apex; whereas the stamens of the Malvæ are perfectly monadelphous. The fruit of this tree, which is cucumber- or bottle-shaped, is used by the natives for fishing-net floats and as water vessels. The native Africans employ the cream-of-tartar-like or sub-acid, mucilaginous pulp as a remedy for dysentery, and poultice inflammations with the leaves. They also use to control excessive perspiration a powder (called *Lalo*) of the dried leaves. Combined with buttermilk it is used in Bombay for its astringent effect in dysentery and diarrhœa, and the sub-acid pulp is given with figs by the Concans for asthma (Dymock).

Description.—The bark is the part employed, and, together with the leaves and flowers of the tree, contains much mucilaginous matter. When fresh it is about five-eighths of an inch in thickness, brown, with a rough epidermis. A section shows the structure to consist of a mixture of pitted wood cells devoid of general arrangement. The cut surface of a transverse section is mottled yellowish-green, and reddish-brown, uniting with the woody fiber of the trunk.

Chemical Composition.—The decoction of the bark decomposes rapidly, owing to the mucilaginous material present; however, this may be prevented by the addition of alcohol, or a small quantity of sulphuric acid. By treatment with alcohol, subsequently evaporating, then digesting with litharge, and extracting with ether, upon evaporating the ether white needles of an extremely bitter taste are obtained, named *adansonin*. These are fusible, dissolve in 6 parts of cold and 3 of boiling ether, are soluble in alcohol, and but slightly so in water; they are not precipitated from their solution by alkalies, and chloride of iron imparts a greenish tinge to the alcoholic solution. Their formula is $C_{28}H_{40}O_{13}$ (Wittstein). Acid malate of potassium, glucose, pectin, and tartaric acid have been found in the pulpy substance surrounding the seeds.

Action, Medical Uses, and Dosage.—According to M. Duchassaing, the bark of this tree possesses febrifuge properties, and although devoid of bitterness, may be beneficially substituted for cinchona; since its introduction into our markets, no satisfactory report has been made of its virtues in this respect. The juice of the fruit is stated to be employed in its native country as a remedy in *putrid* and *pestilential fevers*; and a decoction of the nut, in *dysentery*. A decoction of the bark (1 oz. in 1 quart of water boiled to $1\frac{1}{2}$ pints) is of a reddish color, somewhat resembling that of decoction of cinchona (*Comp. Rend.*, xxvi, 1848, and *Jour. de Pharm.*, June, 1845). A pint and a half of the decoction may be taken in a day.

ADEPS (U. S. P.)—LARD.

“The prepared internal fat of the abdomen of *Sus scrofa*, Linné (class *Mammalia*; order *Pachydermata*), purified by washing with water, melting, and straining. Lard should be kept in well-closed vessels impervious to fat, and in a cool place”—(U. S. P.).

SYNONYMS: *Prepared lard*, *Hog's lard*, *Arunge*.

Source and Preparation.—Lard should preferably be prepared from “leaf fat” obtained from the omenta, mesenteries, and kidneys of the common hog killed during the winter or early spring months. The fat should be thoroughly cleansed from extraneous material, as dirt, blood, etc., and the outer membranous portion of the leaf torn off, after which the perfectly fresh fat should be suspended in the air for a short time. It must then be beaten in a stone mortar until the fibrous, vesicular walls of the cells are broken and the mass becomes uniform throughout, and then heated in a water-bath to 54.4°C . (130°F). Separate the remaining membranous parts, and strain through flannel or linen, after which it may be filtered through paper in a warm atmosphere. It should then be put into impervious containers, cooled, covered with waxed or varnished paper, and kept in a dark, cool, dry place, preferably a cellar, otherwise by the action of the atmospheric oxygen it will speedily become unfit for medicinal use.

Description and Chemical Composition.—Lard used for medicinal purposes should not contain salt; when good it is white, somewhat translucent, of granular appearance, smooth to the touch, somewhat of the consistency of butter, having a faintly-sweetish taste, and a faint, but not rancid, odor; but by exposure to the air it absorbs oxygen, and acquires an unpleasant odor and rancid properties. It is bland to the taste. Water does not dissolve it, and alcohol but slightly; ether, chloroform, benzin, benzol, and carbon disulphide are solvents of it, and so are the essential oils. The concentrated acids decompose it, and caustic alkaline solutions form soap with it, when boiled together. “Specific gravity about 0.932 at 15°C . (59°F). It melts at 38° to 40°C . (100.4° to 104°F) to a perfectly clear liquid, which is colorless in thin layers, and which should not separate an aqueous layer. At or below 30°C . (86°F) it is a soft solid”—(U. S. P.). When melted it combines with resins, wax, and fixed oils, forming ointments, liniments, etc., as may be required. When heated in close vessels, it undergoes a process of destructive distillation, by which palmitic, oleic, acetic, and probably benzoic acids are formed, together with other less important modifications of its constituent fatty principles—i. e., glycerides of oleic, stearic, and palmitic acids; these are found in most animal oils and fats, whose hardness or softness is owing to the relative quantity which they contain of each of these principles (see *Soap*).

OLEIN, or the *Glyceride of oleic acid*, is the liquid principle of oils, and is unknown in the native state. It is an oily fluid, devoid of color, taste, and odor, of specific gravity about 0.900, is partially dissolved by alcohol, but not by water, readily so by ether, and becomes solid at -6.6°C . (20°F). It is convertible by saponification into glycerin and oleic acid. Its formula is $\text{C}_2\text{H}_5.3(\text{C}_{18}\text{H}_{33}\text{O}_2)$. It is said to be used to adulterate olive oil.

STEARIN ($\text{C}_2\text{H}_5.3[\text{C}_{18}\text{H}_{33}\text{O}_2]$), or *Glyceride of stearic acid*, is a crystalline solid somewhat resembling cetaceum, is sufficiently friable to admit of pulverization, freely dissolved by ether at 35.5°C . (96°F), but is completely separated again on cooling, is insoluble in alcohol and water, melts at 62.2°C . (144°F), and is convertible by saponification into stearic acid and glycerin. It may be obtained from lard or mutton tallow, by washing either of these with ether until they suffer no more loss; the stearin remains behind, and may be collected in flakes by boiling it in alcohol and then allowing it to cool. This substance should not be confused with the stearin used in the making of stearin candles, which consists mainly of free stearic and palmitic acids, to which some wax is added to prevent crystallization.

PALMITIN, or *Glyceride of palmitic acid*, is a solid constituent found in the oily portion of the fat. Its formula is $\text{C}_2\text{H}_5.3(\text{C}_{16}\text{H}_{31}\text{O}_2)$. When lard is subjected to pressure at the temperature of 0°C . (32°F .) palmitin and stearin may be separated. The remaining fluid is then known in commerce as *lard oil*. Lard contains from 32 to 40 per cent of solid constituents. Margarin is a mixture of stearin and palmitin.

By incorporating with lard, while hot, a small amount of benzoin or benzoic acid, and stirring until cold, rancidity is prevented. Poplar buds, various balsams, and some volatile oils have the same effect. Pure benzoic acid should not be used, but rather the ordinary acid prepared from the gum, which still retains balsamic qualities.

Adulterations and Tests.—Lard is sometimes treated with common salt to prevent its becoming rancid. Again, for the purpose of yielding a whiter lard and to render the incorporation of water with it less difficult, salt of tartar is added to it by dishonest dealers. Boiling with water, and again fusing the lard, repeating the process if necessary, will remove these impurities. The most largely employed adulterant of lard, however, is cotton-seed oil. When heated, if the lard contains it, the foreign admixture may be detected by its odor. The *U. S. P.* indicates the following tests of the purity of lard: "Distilled water boiled with lard should not acquire an alkaline reaction (absence of alkalies), nor should another portion be colored blue by iodine T.S. (absence of starch). A portion of the water when filtered, acidulated with nitric acid, and treated with silver nitrate T.S., should not yield a white precipitate soluble in ammonia (absence of chlorides). If 10 Gm. of lard be dissolved in chloroform, and the solution mixed with 10 Cc. of alcohol and 1 drop of phenolphthalein T.S., it should not require more than 0.2 Cc. of normal potassium hydrate V.S. to produce a pink tint after strong shaking (limit of free fatty acids). If 5 Cc. of melted and filtered lard be, while warm, intimately mixed, by agitation, in a test-tube with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of deodorized alcohol and adding 2 drops of nitric acid), and the mixture then heated for 5 minutes in a water-bath, the liquid fat should not acquire a reddish or brown color, nor should any dark color be produced at the line of contact of the two liquids (absence of more than about 5 per cent of cotton-seed fats)"—(*U. S. P.*).

ADEPS BENZOINATUS (*U. S. P.*). *Benzoinated lard*.

Preparation.—"Lard, one thousand grammes (1000 Gm.) [2 lb. av., 3 oz., 120 grs.]; benzoin, in coarse powder, twenty grammes (20 Gm.) [309 grs.]. Melt the lard by means of a water-bath. Tie the benzoin loosely in a piece of coarse muslin, suspend it in the melted lard, and, stirring frequently, continue the heat for 2 hours, covering the vessel and not allowing the temperature to rise above 60°C . (140°F). Lastly, having removed the benzoin, strain the lard, and stir occasionally while it cools. When benzoinated lard is to be kept or used during warm weather, 5 per cent (or more, if necessary) of the lard should be replaced by white wax"—(*U. S. P.*).

Action and Medical Uses.—Lard is emollient, and is a convenient article for the formation of ointments, plasters, and liniments. It is also used, without addition, to discuss *tumors*, by friction, or with cataplasm—(Ed.). Sometimes it is added to purgative injections. As an enema it is soothing in *colitis*. Being difficult of digestion it is occasionally used as a laxative for children. Good effects are obtained from it inunction in *scarlatina* and other *eruptive diseases*, in which it allays itching and burning and improves the skin. Applied to the bridge of the nose with friction it alleviates the unpleasantness of *coryza*. When applied to *blistered* or *excoriated parts*, it will be apt to cause ulceration, unless it be free from rancidity. As a lubricating material for manual examinations and operations, it is preferable to petrolatum, as it does not readily mix with fluids. Many of the vegetable alkaloids are soluble in oleic acid (the red oil of soap and candle manufactories), and form with it useful and readily absorbed external applications.

ADEPS LANÆ HYDROSUS (U. S. P.)—HYDROUS WOOL-FAT.

“The purified fat of the wool of sheep (*Ovis Aries*, Linné; class *Mammalia*; order *Ruminantia*), mixed with not more than 30 per cent of water”—(U. S. P.).

SYNONYM: *Purified wool-fat*.

Source and Preparation.—Sheep's wool contains about 45 per cent of a fat known as *suint*, which must be removed from it before it can be made into fabric. This fat, which was formerly known and used as *œsypum*, contains a variable amount of potash, probably from 15 to 35 per cent. *Suint* is obtained by evaporating to dryness, wool-washings; and by proper chemical manipulation, the potassium salts, combined with organic acids taken from the soil by the animal while grazing, and eliminated in the perspiration and adhering to the wool, are separated; and it is estimated that thousands of tons of potash are yearly produced from this source alone. When first prepared, wool-fat consists of about one-third fatty acids in a free condition, besides certain fatty-acid ethers of cholesterin and glycerol. It is the cholesterin fats that enter into the commercial wool-fat. The process for making lanolin is secret. It has a characteristic, wool-like odor, is of a yellow-brown color, and though but partially dissolved by alcohol, dissolves readily in acetone, ether, chloroform and benzol. If this anhydrous wool-fat be now mixed, by kneading, with water, not more than 30 per cent, it forms the Pharmacopœial hydrous wool fat, or *Adeps lanæ hydrosus*.

Description and Tests.—“A yellowish-white or nearly white, ointment-like mass, having a faint, peculiar odor. Insoluble in water, but miscible with twice its weight of the latter, without losing its ointment-like character. With ether or chloroform, it yields turbid solutions which are neutral to litmus paper. Hydrous wool-fat melts at about 40° C. (104° F.). When heated on a water-bath, it finally leaves a residue amounting to not less than 70 per cent, which is transparent while melted, and, when cold, appears as a yellow, tough, unctuous mass, completely soluble in ether or chloroform, and only partially soluble in alcohol. A solution (1 in 50) of a portion of this mass in chloroform, when poured on the surface of concentrated sulphuric acid, gradually develops a deep-brown color at the line of contact of the two layers. When a portion of this mass is ignited, it should not leave more than 0.3 per cent of ash, which should not have an alkaline reaction on litmus (absence of alkalies). If 2 Gm. of the same mass are dissolved in 10 Cc. of ether, and mixed with 2 drops of phenolphthalein T.S., a colorless liquid results (absence of free alkalies), which should be decidedly reddened by 1 drop of normal potassium hydrate V. S. (absence of free fatty acids). If 10 Gm. of hydrous wool-fat be heated, together with 50 Cc. of water, on a water-bath, until the fat is melted, there should result an upper, translucent and light-yellow, fatty layer, and a lower, clear, aqueous layer, which latter should not yield glycerin upon evaporation, and, when a portion of it is heated with some potassium or sodium hydrate T.S., it should not emit vapors of ammonia”—(U. S. P.).

Chemical Composition.—Wool-fat is a mixture mainly composed of ethers of fatty acids, with cholesterin instead of glycerin as the basis.

Action and Medical Uses.—The use of sheep's wool-fat is ancient, and accounts of such employment are handed down by Pliny in his *Natural History*. It was reintroduced as a therapeutic agent by Liebreich, in 1885. It is employed as a non-irritating and efficient ointment base, and possesses marked advantages over like bodies in that it may be mixed with aqueous mixtures and glycerin. It will take up double its weight of water and of glycerin. Lanolin does not become rancid, nor does it leave the skin as soft and pliable as some emollient agents. Much contention has been had as to whether it is absorbed by the skin more than other fats, and as to whether it has any superiority in causing the absorption of drugs by the skin. Stellwagon, Liebreich, and others believe it to be absorbed more rapidly than any other fat. As it is a sebaceous secretion, it undoubtedly tends to favor normal action of the skin. It has been preferred alone as a protective in *mild affections of the skin*, and as an unguent for massage. As a vehicle for salicylic acid, boric acid, iodine and the iodides, and a number of other agents, it has been largely employed in a great variety of *cutaneous affections*.

Related Product.—**THILANIN.** *Thilanine*, *Sulphurated lanolin*, contains sulphur to the extent of 3 per cent. It is prepared by acting upon anhydrous wool-fat with sulphur, aided by heat. It has the consistence of hydrous wool fat, being a yellow-brown, unctuous body. It has been employed as a non-irritating dermic medicament. It is recommended for acute and subacute *eczema of the face*, *scaly eczema of the extremities*, and for the *papulo-vesicular variety* affecting the hands, as well as for other *eczematous eruptions*. *Sycosis*, *acne*, *herpes*, *psoriasis*, and *dermatitis* resulting from chrysarobin, are said to have been benefited by it. It is said to be particularly useful in *itching conditions*. It should be diluted with water or oils when applied to the scalp.

ADIANTUM.—MAIDENHAIR.

The whole plant of the *Adiantum pedatum*, Linné, and *Adiantum capillus Veneris*, Linné.

Nat. Ord.—Filices.

COMMON NAMES.—*Maidenhair*, *Maidenhair fern*.

Botanical Source.—The American species of *Adiantum* is a delicately beautiful and graceful fern, growing from 6 to 15 inches high, with a handsome,

polished, dark-purple or black stipe, forking at the summit; each branch so created supporting simple branches densely clothed with alternate, triangular, oblong pinnæ. These are entire and veined on their lower margin, incised on their upper border, and fruit-bearing. The fruit dots are short, slightly crescent-shaped, and marginal, and covered by an indusium derived from the reflected margin of the lobe. The fronds are erect and present a beautiful appearance. The leaves are slightly bitter, together with a faintly-sweetish, aromatic, feebly astringent taste. The odor is delicately aromatic.

The European species is about 1 foot high, with a brownish or brownish-black stipe, pinnate above, and doubly or thrice pinnate below. The leaflets are irregular, wedge-shaped, obtusely incised, with the fruit dots in a marginal line. It is inodorous, with a sweetish taste, afterward slightly bitter, and feebly astringent.

History and Chemical Composition.—The maidenhair ferns contain a volatile oil, sugar, tannin, mucilage, and a bitter principle. The *A. pedatum* is a common fern in the moist, rich soil of the American woods, and is found also in Eastern Asia. The *A. capillus Veneris* is a native of Europe, but, according to Englemann, is naturalized in Florida, Texas, and Arkansas, and westward to California. The European species is used in preparing a syrup called *Sirap de capillaire*, which is popular in France and Germany as a mucilaginous pectoral. The plants yield their virtues to boiling water, and are used in decoction, infusion, or syrup.

Action, Medical Uses, and Dosage.—Maidenhair is refrigerant, expector-

ant, tonic, and subastringent. In decoction it forms an elegant refrigerant drink in febrile diseases and in erysipelas, and is also beneficial in coughs, chronic catarrh, hoarseness, influenza, asthma, etc. It is likewise reputed efficacious in pleurisy, and in jaundice. The decoction or syrup may be used freely. These plants are highly valued by some practitioners, and deserve investigation. Doses: Decoction (3j to aqua Oj), dose, 1 to 4 fluid ounces. Infusion (3j to aqua Oj), dose, 1 to 4 fluid ounces. Syrup (adiantum 1 part, boiling water 10 parts, sugar 19 parts; infuse, adding the sugar after the syrup has been strained), dose, 1 or 2 table-spoonfuls.

Related Species.—*Asplenium Adiantum nigrum*, Linné. *Black maidenhair*. Habitat, Europe. Mucilaginous. Substituted for the true maidenhairs.

Asplenium Trichomanes. *Spleenwort*. Europe. Also used to adulterate the true species. Neither of the foregoing have, however, the aromatic flavor of the genuine article.

Asplenium ruta muraria, Linné. *White maidenhair*. Indigenous to both Europe and the United States. Used for the same purposes as the medicinal fern.

ADONIS.—PHEASANT'S EYE.

The whole plant of *Adonis vernalis*, Linné.

Nat. Ord.—Ranunculaceæ.

COMMON NAMES.—*Pheasant's eye*, *False hellebore*.

Botanical Source.—*Adonis* is a perennial herb growing from 12 to 15 inches high. The stem is branching, and the leaves many-cleft and sessile. The flowers are large, yellow, and attractive, with 10 or 12 oblong, spreading petals, slightly toothed at the apex. The fruit consists of numerous 1-sided acheniæ.

History and Chemical Composition.—This plant is indigenous to Southern Europe (being especially found in the Crimea) and to Siberia and Labrador. It is one of the very reliable spring flowers, and is found growing in elevated places. It was introduced into medicine by Dr. Bubnow (1879) as a cardiac stimulant. The doctor, who was a student under Prof. Botken, had observed its use by the Russian peasantry as a remedy for dropsy and heart diseases. Linderos (1876) obtained a yellow crystalline substance from the leaves and identified it as *aconitic acid* ($C_6H_5O_6$). In 1882, Prof. V. Cervello isolated its supposed active principle, which he named *adonidine* (*adonidin*). *Adonidin* is a crystalline, non-nitrogenous glucosid, odorless, colorless, and intensely bitter. Ether slightly dissolves it, while it is wholly soluble in alcohol and water. It is practically insoluble in benzol, chloroform, and turpentine. According to Podwissotzki, who has more recently (1888) investigated it, *adonidin* is a mixture composed of *adonitic acid*, *adonidoquercitrin*, *adonidodulcit*, and a couple of glucosids, one of which is the active constituent and named by him *picradonidin*. It is a very bitter, amorphous body, dissolving in alcohol, ether, and water, and said to be a powerful cardiac poison. Tannin precipitates *adonidin* from aqueous or ethereal solutions. *Adonis* root is frequently employed to adulterate black hellebore (*Helleborus niger*).

Action, Medical Uses, and Dosage.—*Adonis* acts very much like *digitalis* and *strophanthus*. It stimulates the muscles of the heart, thereby increasing cardiac contractility, and causes contraction of the smaller arteries throughout the whole body, thus increasing arterial tension. It diminishes the frequency of the pulse and regulates the heart-beat. The remedy acts quickly, even quicker than *digitalis*, and is well tolerated. Diuresis is increased, probably by its action on the renal circulation. Large doses paralyze both the heart and blood-vessels. Unlike *digitalis*, it is not cumulative. The drug should be cautiously used where there is gastro-intestinal inflammation. *Adonidin* in 3-grain doses every half hour, administered by mistake, produced violent vomiting and purging (Durand). Homœopathic physicians speak highly of this drug in *heart disease*, and *kidney affections*. Prof. E. M. Hale recommends its use in *endocardial inflammation*, with *valvulitis*. It is adapted to those cases where the cardiac muscles are laboring to overcome valvular obstruction, or when there is danger of dilatation of the heart from weakening of the muscular tissues. Prof. Hale also intimates that it is valuable in *secondary heart trouble*, resulting from *Bright's disease*, being indicated by an irregular and intermitting pulse, showing weakened heart action, with

venous stasis and dropsy. It is valuable in *cardiac dropsy*. R Specific adonis, gtt. ij, every 2 or 4 hours. In *chronic albuminuria*, with scanty, light-colored urine and delirium, 5-drop doses greatly benefited the patient, and in another case it controlled *uremic convulsions*, which had been frequent, so that they did not again appear for two years, when the patient died (Wilcox). Prof. John M. Scudder said of it: "Its tonic action upon the heart is most marked." He recommended its use in *heart strain* from over-exertion. In one case its beneficial action was observed in one day. The remedy bids fair to take its place alongside of other drugs of the digitalis group in the treatment of all cases in which the latter are now so highly valued. Pallas attributes to the plant emmenagogue properties. The dose of the infusion (3j to aqua 3xij) is a tablespoonful every 2 hours in severe cases; every 4 hours in chronic disease. Specific adonis, $\frac{1}{2}$ to 3 drops. Or, R Specific adonis gtt. x to xx, water 3iv. Mix. Dose, 1 teaspoonful every 2 or 3 hours. Adonidin, $\frac{1}{16}$ grain every 3 or 4 hours.

Fig. 10.

Adonis autumnalis.

Specific Indications and Uses.—As a heart tonic, to be used when cardiac action is weak, with but little blood in the arterial system, with low pressure and shortened diastole, and consequent venous fullness and stasis with increased pressure, feeble, irregular, and intermittent pulse; valvular insufficiency, with regurgitation, and dropsy; vascular enfeeblement with passive, dull, congestive headache; chronic congestion.

Related Species.—*Adonis vernalis*, Linné. Europe and Asia. An almost glabrous annual, having a bitter, acrid taste, but scarcely any odor. Its blossoms are of a yellowish-red hue. A remedy for *fatty heart*.

Adonis autumnalis, Linné. South Europe. Resembles the preceding in properties and appearance, except that it bears crimson blossoms. Both plants have the action and constituents of *Adonis vernalis*.

ÆSCULUS.—OHIO BUCKEYE.

The bark and fruit of the *Æsculus glabra*, Willdenow.

Nat. Ord.—Sapindaceæ.

COMMON NAMES.—Ohio buckeye, Fetid buckeye, Smooth buckeye.

ILLUSTRATION: Gray's Gen. Illust., II, Pl. 177.

Botanical Source.—A small, fetid tree from 20 to 40 feet high, the leaves of which consist of five ovate, or oblong, serrulate, acuminate leaflets, somewhat hairy underneath. The flowers are small and yellowish, and borne in a loose thyrsoid panicle. Each flower has four petals about half the length of its stamens, which are seven in number and curved. The fruit is a prickly capsule, containing the seed.

Fig. 11.

Æsculus glabra.

History.—The Ohio buckeye is found growing along streams and river banks in Ohio, Pennsylvania, Virginia, Kentucky, Indiana, north to Michigan and south to Mississippi. It flowers in May and June, and on account of the unpleasant odor given off the tree is often called fetid buckeye. The fruit contains an abundance of very fine starch, which it is surprising has not yet been introduced into commerce.

Description.—THE NUT (dry) of *Æsculus glabra* does not differ essentially from that of the horse-chestnut, except that it is darker in color, a little smaller in size, is perhaps somewhat more globular, and has a much smaller hilum, the latter being not more than one-third or less than one-half as large as that on the horse-chestnut. It ranges from $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter.

Chemical Composition.—(See *Hippocastanum* and *Gelsemium*).

Action, Medical Uses, and Dosage.—This agent influences the nervous and circulatory systems, having a selective affinity for the portal circulation. In over-doses it affects the cerebro-spinal system somewhat after the manner of nux

vomica. Dizziness, fixation of the eyes, impairment of vision, vomiting, wry-neck, opisthotonos, stupor, and tympanites are among its effects. In lethal doses these symptoms are increased, coma supervenes, and death finally takes place. The dried powder of the nut inhaled causes violent sneezing. The action of buckeye is similar to, but more powerful than that of the horse-chestnut (*A. Hippocastanum*), though some think it less powerful than the latter in its effects upon the portal circulation. It probably acts more powerfully on the spinal than upon the sympathetic nerves. When an excited circulation, with frequent pulse, depends upon disorders of the respiratory and sympathetic nerves, it acts as a decided sedative. The difficult breathing of *non-paroxysmal asthma*, where the dyspnoea is persistent, but does not amount to a paroxysm, is markedly benefited by *æsculus glabra*, while in *coughs*, associated with post-manubrial constriction—a sensation of grasping and tightening—its action is positive. The latter sensation without the cough quickly yields to it. *Phthisis*, *bronchitis*, etc., with dyspnoea and oppression, are palliated by it. *Intestinal uneasiness and irritation*, with a sense of contraction and colic-like pains in the region of the umbilicus, are indications for its use. It is asserted valuable in *intestinal dyspepsia* with these symptoms, and in *hepatic congestion* and *chronic constipation*. Its control over the portal circulation and its attendant disorders is pronounced, and as a remedy for *hemorrhoids* depending upon portal derangements, it has attained a reputation. A sense of constriction in the rectum is the guide to its use. In *female disorders*, with tumid and enlarged cervix uteri, with too frequent and profuse menstruation, it may be employed with advantage. Owing to its powerful action upon the nervous system the drug will repay study. It has been employed with asserted success in *rheumatism* and as a stimulant in *paralysis*. The dose of specific *æsculus glabra* is from 1 to 5 drops.

Specific Indications and Uses.—A sensation of grasping or constriction in the post-manubrial space, or at the supra-sternal notch; cough of spasmodic character, with but little expectoration; asthma, with continual dyspnoea, non-paroxysmal; tightness in the chest and about the heart; bronchial irritation with constriction; sense of constriction, tightness or uneasiness in the rectum, accompanied or not with hemorrhoids; intestinal irritation with constriction and colicky pains near the umbilicus.

Related Species.—*Æsculus parva*, Linné. *Red buckeye*. United States. Southern states, from Georgia and Virginia westward. A small shrub; or in the vicinity of mountains, a tree. Coloring matter, tannin, resin, and a peculiar crystalline body, were obtained from red buckeyes by Mr. Bachelor in 1873, from the testa of the fruit; and a green or brown fixed oil to the amount of 5 per cent, cane sugar, and a little over 2 per cent of a peculiar bitter, acrid, poisonous glucosid, of a brown color, were obtained from the cotyledons, which are principally starch. According to F. Peyre Porcher, M. D., the roots of this tree were preferred to soap for cleansing and whitening blankets, woolen goods, colored cottons, and satins. The fresh nut made into a paste with flour, and also the bruised twigs of the shrub, were used in the swamps of the Santee to stupefy fish, so as to cause them to float that they might readily be taken. A decoction of the nuts was recommended as a topical application to *gangrene*, and a strong decoction of the root held in the mouth was reputed a cure for *toothache*. An excellent starch, which does not become yellow with age, has been prepared from the fruit. It probably possesses the same properties as *æsculus glabra*.

Æsculus flava, Aiton. *Sweet buckeye*, *Large buckeye*. Western United States and mountains of the Appalachian system, from Virginia to Georgia. Grows from 6 to 70 feet high, and has yellow flowers.

Æsculus parviflora, Walter. *Small-flowered buckeye*. United States. Shrub, 2 to 9 feet high, with small, white flowers.

ETHER (U. S. P.)—ETHER.

FORMULA: $(C_2H_5)_2O$. MOLECULAR WEIGHT: 73.84.

SYNONYMS: *Æther fortior* (U. S. P., 1880), *Sulphuric ether*, *Æther sulphuricus*, *Ethyl oxide*, *Hydrate of ethylen*, *Hydric ether*, *Naphtha vitrioli*, *Vinic ether*.

"A liquid composed of about 96 per cent, by weight, of absolute ether or ethyl oxide [$(C_2H_5)_2O=73.84$], and about 4 per cent of alcohol containing a little water"—(U. S. P.).

Preparation.—Sulphuric ether is prepared by the interaction of sulphuric acid and alcohol. From the latter, broadly considered, are thereby abstracted

the elements of water, resulting in the formation of ether, as follows: $2C_2H_5OH - H_2O = (C_2H_5)_2O$. The process, however, is somewhat more complex, and takes place in two phases. It was determined and established by Williamson, in 1852. When alcohol and sulphuric acid are mixed, ethyl-sulphuric acid and water are formed. This ethyl-sulphuric acid being then heated to about 130° to 140° C. (266° to 284° F.) with a fresh portion of alcohol, is decomposed, ether being formed, and sulphuric acid regenerated. The reactions involved are expressed by the following formulæ:

On this principle the present method of preparing ether is now carried out, known as the "continuous process" of Boullay. It consists in mixing together 2 measures of alcohol, specific gravity 0.830, and 1 measure of concentrated sulphuric acid; the mixture is submitted to distillation in a capacious retort, which must be connected with an efficient condenser. Through the tubulure of the retort a tube is introduced, which is in communication with a reservoir of alcohol, designed to maintain a supply of spirit sufficient to keep the amount of liquid at a uniform level in the retort during the course of subsequent distillation. The temperature is then rapidly raised so as to maintain the mixture in steady ebullition. The liquid which passes over consists almost entirely of ether and water, mixed with a small portion of alcohol which has distilled over unchanged. This process may go on without interruption until a quantity of alcohol, about thirty times as great as that originally taken, has become converted into ether. Isethionic acid is gradually formed in the residue.

The crude ether may be purified by agitating it with an equal bulk of water containing one-fortieth its weight of caustic soda in solution; the water combines with the alcohol, and the soda neutralizes any sulphurous acid that may have distilled over; the liquid separates into two layers, the upper one of which consists of ether, holding a little water in solution. The ether may be freed from water by allowing it to stand for a day or two upon quicklime, or upon chloride of calcium; it is then to be rectified by the heat of a water-bath, and condensed in vessels kept cool with ice-cold water. The purification of ether may be accomplished as directed by the *British Pharmacopœia*, a process yielding a better product than the old *U. S. P.* process: "Take of ether, distilled water, of each, 2 pints (Imp.); lime, recently burned, 1 ounce (av.); chloride of calcium, 4 ounces (av.). Put the ether with 1 pint (Imp.) of the water into a bottle, and shake them together; allow them to remain at rest for a few minutes, and when the two liquids have separated, decant off the supernatant ether. Mix this with the remainder of the water, and again, after separation, decant as before. Put now the washed ether, together with the lime and chloride of calcium, into a retort, to which a receiver is closely attached, let them stand for 24 hours, then distill with the aid of a gentle heat. Specific gravity not exceeding 0.720"—(*Brit. Phar.*).

Ether is obtained on a large scale, in the U. S. Naval Laboratory, by steam, as described by E. R. Squibb, M. D., in *Am. Jour. Pharm.*, 1856, p. 385. Squibb's ether is an exceptionally pure product, and is often preferred for anæsthetic purposes in this country.

Description.—The name "sulphuric ether," is a misnomer, at least as far as regards composition, there being no sulphur present. The *U. S. P.* describes official ether as "a transparent, colorless, mobile liquid, having a characteristic odor, and a burning and sweetish taste. Specific gravity 0.725 to 0.728 at 15° C. (59° F.); or 0.714 to 0.717 at 25° C. (77° F.). Soluble in about ten times its volume of water at 15° C. (59° F.), with slight contraction of volume. Miscible, in all proportions, with alcohol, chloroform, benzin, benzol, fixed and volatile oils. Ether boils at about 37° C. (98.6° F.), and it should, therefore, boil when a test-tube, containing some broken glass and half-filled with it, is held for some time in the hand. Ether is highly volatile and inflammable. Its vapor, when mixed with air and ignited, explodes violently"—(*U. S. P.*).

Pure ether, when freshly made, causes no alteration in the color of litmus or turmeric paper; but, by exposure, it absorbs oxygen, oxidizes slowly, and decomposes, yielding aldehyde, glyoxalic, acetic and formic acids. By evaporation,

ether produces intense cold. Pure ether dissolves one eightieth of its weight of phosphorus; but if it contains alcohol, only one two-hundred-and-fortieth; it also dissolves a very small portion of sulphur, bromine, and iodine, but the solutions of the latter decompose by keeping. It abstracts bichloride of mercury, chloride of gold, bichloride of platinum, and the perchloride of iron, from their watery solutions. It dissolves most resins, pyroxylic spirit (wood alcohol), many fats, volatile oils, gallic acid, many of the vegetable alkaloids, urea, gun cotton, chromic acid, oleates of heavy metals, tannic and many other organic acids, caoutchouc, phosphorus, bromoform, chloroform, iodoform, benzin, benzol (benzene), alcohols, iodides, bromides, chlorides, and some sulphides of metals.

M. Grimault has given a method by which pure ether may be gelatinized, or, if required, various substances may be dissolved in it, as camphor, cyanide of potassium, morphine, conine, etc. If 4 measures of pure ether are added to 1 measure of white of egg, and the mixture be briskly agitated, the albumen will soon be seen to swell, and absorb the entire ether, forming a thick collodion, which soon becomes an opaline, trembling jelly, and does not separate into the two ingredients of which it is composed. Applied to the skin and covered with a band of cloth, or caoutchouc, it speedily causes redness without vesication; and when it begins to dry, a new layer may be applied if necessary. If the mixture be exposed to a water-bath at 70° C. (158° F.), an almost instantaneous solidification is obtained without the separation of ether.

"Ether should be kept in well-stoppered containers, preferably in tin cans, in a cool place, remote from lights or fire"—(*U. S. P.*). It has also been shown by Schönbein that pure ether changes its properties when in contact with air or oxygen, and exposed to diffused light. Under these conditions, hydrogen peroxide, ozone, aldehyde, and ethyl peroxide, are liable to be formed, and may become the cause of dangerous, spontaneous explosions (Krauch). There are in commerce, varieties known as "concentrated ether," and "washed ether." They should not be employed either in medicine or pharmacy, in consequence of their uncertain composition. The virtues of many agents containing vegetable oils and resins, may be taken up by ether in the form of tincture, when, by evaporating the ether, the desired active product is left behind; this is the case with lobelia seeds, capsicum, scutellaria, podophyllum, ptelea, stillingia, xanthoxylum berries, iris, and several other preparations.

Tests.—Ether may be recognized by its striking physical properties, especially its peculiar odor and taste, its complete solubility in alcohol, and its sparing solubility in water. If a mixture of ether and water produce a white color, oil of wine is present; the ether may be separated by distillation at a gentle heat. Absolute ether does not dissolve aniline-violet, according to Stephanelli, but gives a decided coloration if but 1 per cent of alcohol be present. The *U. S. P.* directs the following tests: "The color of light-blue litmus paper moistened with water, should not be changed when the paper is immersed in ether for ten minutes. Upon evaporation, ether should leave no residue. If 10 Cc. of it be poured, in portions, upon clean, odorless blotting paper, and allowed to evaporate spontaneously, no foreign odor should become perceptible when the last traces of ether leave the paper. When 20 Cc. of ether are shaken in a graduated tube, with 20 Cc. of water, just previously saturated with ether, the ethereal layer, upon separation, should not measure less than 19.8 Cc. (absence of an undue amount of alcohol or water). If 10 Cc. of ether be shaken occasionally, within one hour, with 1 Cc. of potassium hydrate T.S., no color should be developed in either liquid (absence of aldehyde, etc.)"—(*U. S. P.*).

Action and Toxicology.—Ether taken by mouth has at first a sweetish taste, followed by great heat and pungency. In moderate doses it acts powerfully on the mouth, throat, and stomach, allays spasm, and relieves flatulence, without increasing arterial action. After the burning in the stomach has subsided, a cooling sensation, quickly diffusing itself throughout the system, is experienced. It first excites the cerebral functions, then depresses. In somewhat larger doses it causes intoxication. The heart's action is increased, the face becomes flushed, the surface warm, and in a very short time sweating takes place, similar to, yet less transient than that from alcohol, and quickly followed by a sense of contentment and mental quietude, associated with a desire to sleep. Seldom does its

effect last more than 1 hour, even when 2 fluid drachms have been swallowed. Individuals may become so accustomed to taking ether that large quantities may be consumed in a day. Intoxication from ether drinking is reported common in Ireland (*British Med. Jour.*, 1890). Life has not been directly destroyed by ether as a *fluid*, but several deaths have resulted from inhalation of the *vapor*. (For the effects of inhalation, see *Etherization*). In very large doses it causes nausea, increased flow of saliva, giddiness, and suspension of sensation and voluntary motion. Locally applied, it produces rubefaction, and sometimes vesication, if its evaporation be prevented; but it acts as a refrigerant, occasioning a great degree of cold, when suffered to evaporate.

Medical Uses and Dosage.—Ether is narcotic, stimulant, antispasmodic, refrigerant, and carminative. Its antispasmodic and stimulating properties render it efficient in *spasmodic asthma*, *flatulent colic*, *hiccough*, *subultus tendinum*, *cramp of the stomach*, *nervous headache*, *sick headache* attended with double vision, *photopsy*, and *nausea or vomiting*, *lowness of spirits*, *gastrodynia*, *hysteria*, *dyspnoea*, *palpitation*, and *gout of the stomach*; it is also efficacious to overcome the painful spasms occasioned by *urinary or biliary calculi*, during their passage through the ducts or tubes; for this purpose it is frequently conjoined with oil of turpentine. As an antispasmodic, it will be found useful in all forms of spasmodic action, unattended by inflammation, as *chorea*, *epilepsy*, *tetanus*, etc.

On account of its emulsifying properties when combined with fatty matter, as codliver oil, ether has been used to aid digestion, and tissue production, in *phthisis*. By stimulating the gastric and duodenal tracts, it secondarily influences the pancreatic secretion, which then readily acts upon the emulsified oil, making its digestion more perfect, and thereby adding to the nutrition of the body.

When applied locally, as a refrigerant, allowing it to evaporate, ether is useful in *nervous* and other *headaches*, in *external inflammations*, *strangulated hernia*, etc. As a rubefacient, it may be employed in all cases where this effect is indicated, by checking its evaporation. The spray of ether, directed upon painful parts, has been used as a local anæsthetic, as well as for minor surgical operations. Sprayed upon the lumbar region, it eases the pains of *labor*; and uterine contraction, with the control of hemorrhage, may be accomplished by spraying it on the lower part of the abdomen. Applied by vapor, or upon a pledget of cotton, it relieves *ear-ache*, and combined with camphor and inserted into carious dental cavities, it controls *toothache*. *Pediculi pubis* are destroyed by it, and it is fatal to *ascarides* when used by rectal enema. Ether has been subcutaneously injected in *sciatica*, *lumbago*, and other *neuralgias*, in *sudden syncope*, and in the prostration following pulmonary and post partum hemorrhages, convulsions, and in *chloral* and *opium poisoning*, etc. The quantity injected should be from 10 to 15 minims, and care should be had not to inject deeper than the fascial tissues. When 1 fluid ounce of pure ether is well agitated, in a closed bottle, with 2 fluid drachms of white of egg, a tremulous jelly is formed, termed *gelatinized ether*, which may be spread on cloth, and applied upon painful parts, to act as an anæsthetic. It should be covered with a compress or some body to prevent too rapid evaporation; and, on account of its want of permanency, should only be made when required for use.

The dose of ether varies from 10 to 60 drops, which should be repeated at short intervals. It may be given in water by triturating it with a little spermaceti; and is frequently combined with opium, ammonia, or valerian. *Capsules of ether*, or *pearls of ether* (Clertin), are prepared by inclosing 5 or 6 minims of pure ether in capsules made of gum and sugar; they afford a very pleasant and efficacious mode of administering this fluid. They should be freshly prepared every 10 or 12 months, as they part with their ether. Lortet has found these capsules useful in *tænia*. He gives at one dose 2 ounces of ether, followed in two hours by 1 ounce of castor oil.

Etherization.—Ether (formerly under the name of *Letheon*) is very extensively employed as an anæsthetic agent, for the prevention and removal of pain and spasm, and whenever severe operations are about to be performed. While equally as efficient as chloroform, it is less pleasant to inhale, and not quite so rapid in producing anæsthesia. It is, however, much safer than chloroform, as death, when produced, results from respiratory paralysis, the heart continuing to beat after respiration has ceased. Such being the case, when respiratory action

fails, artificial respiration may be resorted to, whereas, with chloroform, death is produced mainly by cardiac paralysis, which is further beyond the power of the physician to remedy. Not more than $3\frac{1}{2}$ per cent of chloroform should be present in the inspired air, whereas the air may contain from 60 to 70 per cent of ether with safety. It occasions vomiting less readily than chloroform. On the other hand, it is very inflammable and cannot be so well used near lights, as is sometimes required in obstetric practice. Here chloroform is to be preferred. Ether was the first agent to be used, as a general anæsthetic by inhalation, for the performance of great surgical operations. Under partial anæsthesia, Dr. John C. Warren, at the request of a Boston dentist, Dr. W. T. G. Morton, performed a severe surgical operation at the Massachusetts General Hospital, Oct. 15, 1846. On the succeeding day, Prof. Hayward operated upon a patient under full anæsthesia. Dr. C. T. Jackson, of Boston, at once informed Dr. Warren that he had first imparted to Morton a knowledge of its value in the painless extraction of teeth, which was the use Dr. Morton had made of it.

The phenomena produced by the inhalation of this anæsthetic are mainly as follows: When first inhaled, some faucial irritation is produced, as well as cough and shortness of breath. The extremities prickle; exhilaration, with talkativeness, or laughing, crying, praying, or raging, with a sense of lightness, is felt, and gradually all the senses are blunted or perverted, that of pain being lost before that of touch. This is a good stage for slight operations, and for midwifery emergencies. Gradually consciousness is lost, and gradual muscular relaxation, sometimes preceded by tetanic rigidity, takes place. The circulation and respiration are quickened, though the latter is somewhat shallower than when normal; warmth of skin with perspiration ensues, as well as contraction of the pupil. Continuing the inhalation, complete insensibility and muscular relaxation take place, the breathing becomes slow, deep, and even stertorous, the pulse slow and feeble, the pupil dilated, the cutaneous surface moist, cool, and livid or cyanotic. Stertorous breathing is the signal for withdrawing the anæsthetic, for then respiratory paralysis is approaching. The best stage for operating is that when muscular relaxation is complete, so that the arm, if lifted and dropped, will fall helpless, and when the conjunctiva may be touched without flinching on part of the patient. As to the method of administration, it may be used in a similar manner to that for inhaling chloroform (see *Chloroformum*); about from 4 to 6 minutes will be required before anæsthesia occurs, the patient generally inhaling the vapor from $1\frac{1}{2}$ to 2 fluid ounces of the liquid; it should be used in small quantities at a time, and any depression of the pulse, or spasmodic symptoms, and particularly stertor, occurring during its inhalation, indicate danger, and its further inhalation should be discontinued. Artificial respiration, stimulants, cold water to the head and spine, electro-magnetism, etc., are the means to overcome its unpleasant effects. To produce anæsthesia, chloroform is more commonly preferred, as it is pleasanter and more easily administered. For some time the *A. C. E. Mixture* (1 part of alcohol, 2 parts of chloroform, and 3 parts of ether) was quite popular, but is now comparatively seldom employed. The practice of frequently inhaling ether, is dangerous, often causing inflammation of the brain, or insanity.

A peculiarity of ether inhalation, is the disposition to use indecent language and to say things of which the patient is afterwards heartily ashamed. Thus, the patient may become amorous, pugnacious, lascivious, or vulgar, and may reveal long-kept secrets. Roaring, and rushing sounds of wind, or rushing water, hysterical phenomena, cerebral and pulmonary congestion, acute nephritis, and even mania, may follow its use. Vomiting often occurs as an after-effect, and is quite persistent. Ether may be employed to anæsthetize patients about to undergo surgical operations, no matter how severe, and either it or chloroform is now universally employed for this purpose. Being adapted to the whole range of operations, it is unnecessary to enumerate them here. Not only is it used to produce anæsthesia and analgesia, but to overcome spasm and muscular resistance. For the latter purpose, it is of great value as an aid in reducing luxations and fractures. To mitigate the pangs of labor it is useful, but chloroform is preferable, as its vapor is not inflammable, and it may be used near lights. Besides the majority of the conditions for which it is internally given (see above), it

may be inhaled for the relief of *dysmenorrhœa*, *hydrophobia*, *puerperal* and other *convulsions*, *whooping-cough*, *laryngismus stridulus*, *croup* (spasmodic), *mania*, *delirium tremens*, etc. In *puerperal eclampsia*, it should be used to control convulsive action until appropriate remedies may be given. In the *hysteria* following child-birth, it is an excellent antispasmodic, as well as in *infantile convulsions* not depending "upon a morbid irritability of the nervous system with organic change" (Locke). Distressing *after-pains* are safely and quickly overcome by a few whiffs of ether, and the same procedure relieves *nervous headache*. *Lead colic* is relieved, both by the rectal enema of ether and by its inhalation.

Specific Indications and Uses.—Pain, or convulsive action, with feeble circulation, and cool, pallid face; headache, with enfeebled circulation. To produce anæsthesia, for the performance of surgical, gynecological and obstetrical operations.

ÆTHER ACETICUS (U. S. P.)—ACETIC ETHER.

FORMULA: $C_2H_5C_2H_3O_2$. MOLECULAR WEIGHT: 87.8.

SYNONYMS: *Ethyl acetate*, *Naphtha aceti*.

"A liquid composed of about 98.5 per cent, by weight, of ethyl acetate [$C_2H_5C_2H_3O_2=87.8$], and about 1.5 per cent of alcohol containing a little water" —(U. S. P.).

Preparation.—Formerly, acetic ether was prepared by distilling a mixture of acetate of lead, sulphuric acid, and alcohol. At present, however, sodium acetate is generally employed instead of the lead salt. For this purpose it is previously deprived of its water of crystallization by the application of heat. The reaction takes place according to the following equation:

The process of the *British Pharmacopœia* is as follows: "Take of rectified spirit, 32½ fluid ounces (Imp.); sulphuric acid, 32½ fluid ounces (Imp.); acetate of sodium, 40 ounces (av.); carbonate of potassium, freshly dried, 6 ounces (av.). To the spirit slowly add the acid, keeping the fluid cool, and, the product being cold, add the acetate, mixing thoroughly. Distill 45 fluid ounces (Imp.). Digest the distillate with the carbonate of potassium for three days in a stoppered bottle. Separate the ethereal fluid, and again distill until all but about 4 fluid ounces have passed over. Preserve the resulting acetic ether in a well-closed bottle, and in a cool place"—(*Brit. Phar.*).

Description and Tests.—Acetic ether, as required by the *Pharmacopœia*, is "a transparent, colorless liquid, of a fragrant and refreshing, slightly acetous odor, and a peculiar acetous and burning taste. Specific gravity, 0.893 to 0.895 at 15° C. (59° F.). Boiling point, about 76° C. (168.8° F.). Soluble in about 8 parts of water at 15° C. (59° F.); miscible, in all proportions, with alcohol, ether, fixed and volatile oils. Acetic ether is readily volatilized, even at a low temperature. It is inflammable, burning with a yellowish flame and an acetous odor. It is neutral to litmus paper. When evaporated in a capsule, acetic ether should leave no residue. If a portion be allowed to evaporate spontaneously from clean, odorless blotting paper, the final odor should not resemble that of pineapples (absence of butylic and amylic derivatives). When 25 Cc. of acetic ether are shaken, in a graduated tube, with 25 Cc. of water just previously saturated with the ether, upon separation, the ethereal layer should not measure less than 24.5 Cc. (absence of an undue proportion of alcohol or water). When a small portion of the ether is carefully poured upon some concentrated sulphuric acid, no dark ring should be developed at the point of contact of the two layers (absence of readily carbonizable, organic impurities)" —(U. S. P.).

Acetic ether is decomposed by acids and alkalis. When it burns, acetic acid is developed during the combustion. Acetic ether is always present in small quantity in wine vinegar, which owes its flavor to this compound. It is a good solvent for the essential oils, resins, pyroxylin, cantharidin, and other substances; mixed with an alcoholic solution of caustic potash, the mixture is immediately decomposed into acetate of potassium, and alcohol. Acetic ether readily dissolves chloride of calcium, and forms a crystallizable compound with it, which yields the ether unchanged on the application of heat. One part of acetic ether, and

3 parts of alcohol (80 per cent), form the *Spiritus Aceticus Æthereus*. Sulphur and phosphorus are both very slightly soluble in this liquid. Though not so inflammable as ether, it should not be kept near fire or lights. It should always be kept in a dark, cool place, in closely-stoppered bottles. In contact with the atmosphere, especially if moisture be present, free acetic acid will be produced. Acetic ether was first made, in 1759, by Lauraguais, who, to produce it, distilled alcohol with concentrated acetic acid.

Action, Medical Uses, and Dosage.—Acetic ether is somewhat similar in its operation to ether, but is milder, more agreeable, and more diaphoretic. It has been used in *nervous fevers, putrid fevers, cardialgia, spasmodic vomiting, and asthenic affections of the stomach and bowels*. By inhalation, it relieves *nervous excitation, nervous coughs, and syncope*. Dose, from half a fluid drachm to 2 fluid drachms, in a sufficient quantity of water. This agent is less volatile and less inflammable than sulphuric ether.

Related Preparation.—*ETHER FORMICUS*. *Formic ether, Æther formicus*. Formula: $C_2H_4CHO_2$. Molecular Weight: 73.83. Bucholz produced this ether in 1782. It is prepared by mixing with 88 per cent alcohol (7 parts) dry formate of sodium (8 parts), adding to the mixture in the retort concentrated sulphuric acid (11 parts); this creates sufficient heat to disengage the formic ether. If the distillate be acid, an equal quantity of water, holding in suspension magnesia or lime, should be added to it, and the mixture shaken. Finally, it should be treated with calcium chloride, from which it may be rectified.

Formic ether has a specific gravity of 0.918 at about 17° C. (62.6° F.), and boils near 55.5° C. (132° F.). It is a limpid, colorless liquid, with a powerful odor, recalling that of bitter almonds. To the taste it is pungent. It is freely soluble in alcohol, wood alcohol, volatile and fixed oils, and sulphuric ether, and less soluble in water (1 in 10). It is inflammable, and should be cautiously used near fire and lights. This agent markedly reduced the temperature (34° C.) in animals, with signs of asphyxiation, and relaxation of the muscles, and anæsthesia. In man, only symptoms of drowsiness were produced by 90 to 105-grain doses (Byasson). It seems to be eliminated by the kidneys.

ETHER METHYLICUS.—METHYL ETHER.

FORMULA: $(CH_3)_2O$. MOLECULAR WEIGHT: 45.90.

SYNONYMS: *Methyl oxide, Methoxymethane, Methylic ether, Methylene hydrate*.

Preparation.—This substance is produced by abstracting the elements of water from methyl alcohol: $2CH_3O - H_2O = C_2H_6O$. It is prepared by heating a mixture of 1.3 parts of pure methyl alcohol and 2 parts of sulphuric acid, in a flask, gradually raising the temperature to 140° C. (284° F.). The gas is washed by passing it through a solution of caustic soda (*Chem. News*, Vol. 30).

Description.—Methyl ether is a colorless gas, with an ethereal odor. It burns with a pale flame. Its specific gravity is 1.617, referred to air, or 23, referred to hydrogen, as the standard of unity. One great objection to it as a popular remedial agent, is the fact that it is gaseous at ordinary temperatures. Water dissolves 33 times its volume. Alcohol and methyl alcohol dissolve it more freely, while sulphuric acid will dissolve 600 times its volume, with increase of temperature. In the latter case, the gas is freely liberated upon the addition of water.

Action and Medical Uses.—This gas, taken up to saturation, by concentrated ethylic ether, at a temperature of 0° C. (32° F.), forms the anæsthetic fluid of Dr. B. W. Richardson, of England—methyl-ethylic ether. This compound, however, must not be confounded with that known also as methyl-ethyl ether, or methyl-ethyl oxide (see *Related Compounds*, below). As it is very volatile and highly inflammable, it should be at once placed into well-secured bottles and kept in the cold. According to Dr. Richardson, it is a rapid and perfectly safe anæsthetic, and more closely approximates what a true agent of this kind should be than any other yet presented to the profession. A drachm or two inhaled, effects anæsthesia quickly. It simply destroys sensibility, without interfering with will, consciousness, or muscular power, and without occasioning spasm, syncope, asphyxia, or any excitation of the nerve centers (*Lancet*, April 2, 1870). In consequence, however, of the instability of this preparation, and its by no means agreeable odor, it has not come into general use as an anæsthetic.

Related Compounds.—*ETHER METHYL-ETHYLICUS*, *Methyl-ethyl oxide, Methyl-ethyl ether*. This compound is produced by the interaction of methylate of sodium and iodide of ethyl,

the vapors from the retort being passed through a weak solution of soda, at a temperature of about 15° C. (59° F.) by which volatile impurities are separated, and the product condensed in cold receivers. It forms an exceedingly inflammable, colorless fluid, of an odor peculiar to itself. It boils at 11° C. (51.8° F.). It has had a limited use as an anæsthetic, and must not be confused with Richardson's anæsthetic, known by the same name—methyl-ethyl ether.

METHYLAL ($\text{CH}_3[\text{OCH}_2]_2$), *Methylen-dimethyl ether*. This compound is the result of the action of a mixture of sulphuric acid and dioxide of manganese on methyl alcohol, and rendered pure by fractionally distilling the crude substance, and employing means to abstract therefrom the elements of water. It forms a limpid, colorless fluid, having a pungent, ether-like odor. It dissolves in water (1 in 13), alcohol, fixed and essential oils, and in ether. It is unaffected by alkaline bodies, but is decomposed by sulphuric acid. Its density is 0.855; its boiling point about 42° C. (106.6° F.). It was proposed by Dr. B. W. Richardson as a narcotic and anæsthetic. It has also been employed to relieve painful and spasmodic affections, as *colic*, *angina pectoris*, *asthma*, *intestinal neuralgia*, and *tetanus*. It has been successfully employed as a hypnotic for the *insane*. It may be given in ʒj or ʒjss doses in water or syrup, or orange flower water, largely diluted. It is but little used.

ÆTHYL BROMIDUM.—BROMIDE OF ETHYL.

FORMULA: $\text{C}_2\text{H}_5\text{Br}$. MOLECULAR WEIGHT: 108.69.

SYNONYMS: *Hydrobromic ether*, *Monobromo ethane*, *Æther hydrobromicus*.

Source and History.—Bromide of ethyl was discovered by Serullas, in 1827, who made it by acting upon phosphorus with bromine, in contact with alcohol. In 1852, Mr. E. Robin experimented upon birds with this agent, and was pleased with its action as an anæsthetic. He stated that it produced rapid effects, without any subsequent suffering or distress. In 1865, Dr. Nunnally experimented further; and afterward, Dr. Rabuteau (1876) made some careful investigations regarding its action; while still more recently, Drs. Lawrence Turnbull and R. J. Levis, of Philadelphia, have brought the agent prominently before the medical profession, and to them belongs the credit of its more recent introduction into medicine.

Preparation.—The original process for making bromide of ethyl was troublesome and dangerous. It was improved upon by De Vrij, bromide of potassium being decomposed in contact with alcohol, by means of sulphuric acid. This is the favored process at the present day, and we call attention to the two practical modifications of it given in the *Amer. Jour. Pharm.*, May, 1880. The articles were written by Lawrence Wolff, M. D., and Prof. Jos. P. Remington. We prefer that of Prof. Remington (given below), from the fact that he adds the alcohol slowly to a warmed mixture of the sulphuric acid, water, and bromide of potassium, although the formula of Dr. Wolff will give satisfactory results.

Take of bromide of potassium, in crystals, 58 parts; sulphuric acid, 44 parts; alcohol, 44 parts; water, 28 parts. Introduce the mixed water and sulphuric acid (observing precautions regarding mixing sulphuric acid and water, given in article on *Hydrobromic Acid*) into a tubulated retort of 116 parts capacity, and when the mixture has become cool, add the bromide of potassium. Then place the retort on a sand-bath, and fix in its tubulure a funnel-tube, and connect the exit with a condenser; heat the mixture to 116° C. (240.8° F.), and then slowly supply alcohol until the 44 parts are consumed. The heat, during the reaction, must be maintained between 100° C. (212° F.) and 116° C. (240.8° F.), and be continued after the alcohol is added, until it reaches 116° C. (240.8° F.), when the operation must be discontinued. The distillate, crude ethyl bromide, must be very carefully purified, as follows: Mix it with an equal bulk of distilled water, previously rendered distinctly alkaline with caustic soda or caustic potash, and agitate the mixture violently. After it has separated into two layers, marked by a clear line of demarcation, siphon the lower liquid into a retort, add a little chloride of calcium, and distill the mixture upon a water-bath. This distillate must be redistilled from a clean retort, by means of an expanded steam- or water-bath.

Description.—Bromide of ethyl is transparent, colorless, volatile, has an agreeably ethereal odor, and a penetrating, sweetish taste. It is not inflammable, neither will it explode. Its specific gravity is 1.420 (Remington), and its boiling point 40° to 41° C. (104° to 105.8° F.). It dissolves freely in alcohol and ether,

but is comparatively insoluble in water. It should, in all cases where intended for use as an anæsthetic, be perfectly volatile at ordinary temperatures, and, when evaporated from a clean glass or porcelain plate, by exposure, it should not leave a stain, and the plate should be devoid of all odor.

Action and Medical Uses.—We have noticed the remarks of Drs. Lawrence Turnbull, and R. J. Levis, of Philadelphia, Pa., relative to the safety and efficacy of ethyl bromide as an anæsthetic. These gentlemen have employed this agent in a great number of cases without any serious accident occurring, and consider it fully as safe an anæsthetic as ether, decidedly more so than chloroform, and superior to either; but a pure article must always be employed. Dr. Levis states that its action is rapid, and that the patient quickly recovers from its effects. Its vapor is non-inflammable, and not irritating to the respiratory passages, influencing respiration but slightly, if at all; the circulation is not affected by it, except sometimes a slight augmentation in the rapidity of the heart's action, and perhaps a trifling increase of arterial tension or pressure. Nausea and vomiting are said to occur less frequently (more liable, according to Agnew, Terillon, and others) than with ether or chloroform, and its inhalation does not occasion cerebral anemia, or fatal syncope from cardiac depression, so frequently following the employment of chloroform. Clinically, several disasters have followed its use, and it is now practically abandoned. *Minor operations* have been performed under its use as a local anæsthetic, applied with an atomizer.

Related Product.—ETHYLENE BROMIDE ($C_2H_4Br_2$). This substance must not be mistaken for *Bromide of ethyl*. It is prepared by the direct combination of ethylene gas (olefiant gas), with bromine. It is a pale-brownish fluid, sweet, with a burning after-taste, and an odor not unlike that of chloroform. At $0^\circ C.$ ($32^\circ F.$) it congeals as a snow-like mass of crystals. It boils at $131^\circ C.$ ($267.8^\circ F.$). It possesses feeble and slow anæsthetic qualities. Inhalations of it may poison. *Epilepsy* has been successfully treated with it.

ETHYL IODIDUM.—ETHYL IODIDE.

FORMULA: C_2H_5I . MOLECULAR WEIGHT: 156.

SYNONYMS: *Æther hydriodicus*, *Hydriodic ether*, *Iodide of ethyl*.

Source and History.—This preparation is now made by distilling a mixture of amorphous phosphorus, iodine and alcohol. Gay-Lussac (1815) was the first to prepare it, producing it by distilling hydriodic acid and absolute alcohol, and setting the ether free with water.

Preparation.—When ordinary phosphorus is employed, the process is as follows: Take 10 parts of iodine, 5 parts of absolute alcohol, and 1 part of phosphorus. Place the alcohol in a retort and add a small amount of iodine; then add a small quantity of the phosphorus, from time to time, until the liquid becomes colorless; a fresh portion of iodine is then added, and then a fresh quantity of phosphorus, and so continued until all the iodine and phosphorus have been added. Cool the mixture thus obtained by immersing the bulb of the retort after each addition, in cold water, to moderate the action. After the reaction has terminated, the liquid is to be distilled by the heat of a water-bath, taking care that the iodine (as shown by its brown color) is in slight excess. The distillate should be washed with water, treated with chloride of calcium, and redistilled. The use of amorphous phosphorus, as suggested by Personne, in 1861, is now generally adopted, the proportions used, and the procedure, being practically the same as indicated for ordinary phosphorus, except that the mixture of alcohol, phosphorus, and iodine, is allowed to stand for 24 hours to complete the reaction.

Description.—Hydriodic ether is colorless, and has no acid reaction. Its odor is ethereal, its taste pungent, but less sharp than that of sulphuric ether. Its density is 1.9206 at $22.2^\circ C.$ ($72^\circ F.$); it boils at $71.1^\circ C.$ ($160^\circ F.$), and is not inflammable. When thrown on burning coals, it expands in purple vapor. It is not decomposed immediately by potassium hydroxide, nor by nitric or sulphurous acids, but sulphuric acid decomposes it, and sets free a part of the iodine. The action of the air discolors it slightly, by liberating a little iodine, which may be readily removed by the alkalis, or mercury, a globule of which, thrown into the vial, is sufficient to retain the ether in a state proper for inhala-

tion. Its density admits of its being kept under water, in which it is practically insoluble; but it is soluble in alcohol.

Action, Medical Uses, and Dosage.—The physiological effects of this ether are stated to be: "After some inhalations, an impression of calmness and satisfaction announces that the hydriodic ether acts at first conformably with the sedative properties of the other ethers employed in medicine. The respiratory motions are carried on with readiness and fullness, advantageous to the circulation; but the antispasmodic action of the ethereal vapor, which favors the absorption of the remedy, is soon followed by the influence of the absorbed iodine. The increase of vigor ceasing to be limited to the thoracic muscles, extends to the muscular system. The appetite is developed, the secretions are increased, the genital feelings become more sensitive, the pulse acquires fullness, and the vivacity of the feelings, and the activity of the intellect, prove that the impulse given to the other organs extends to the brain also. Such are the effects that 4 daily inhalations, of 10 minutes each, produced on Dr. Huette. As to accident, he never experienced anything but a little coryza, and frequently, when the vapor had been too concentrated, a slight feeling of pressure in the temples."

He thinks that in many cases there will be an advantage in substituting the inhalation of hydriodic ether for the other preparations of iodine, observing that inhalation permits the fractioning of the doses to any extent, and causes the absorption of the medicine by more extended surfaces, more generally accessible in all their parts, and better calculated for the absorption of the smallest medicinal atoms, than are the digestive organs (*Am. Journ. Pharm.*, xxiii., 156). It has likewise been advantageously employed in inhalation by several physicians of this country in chronic diseases of the air passages, especially in *membranous phthisis* and *bronchial affections*. It is comparatively safe as a medicinal agent.

Ethyl iodide is a powerful anæsthetic when inhaled, but it must be entirely free from phosphorus. It is a most valuable remedial agent, patients being able to bear a much larger quantity of iodine in this form than they possibly could bear in any other manner. It has been used internally with success in *scrofulous diseases*, by inhalation in *diseases of the lungs and heart*, and as a local application to *painful and irritable ulcers*, and *scrofulous ulcers*. Hydriodic ether is recommended by Dr. Huette, by way of inhalation, as a remedial agent in several diseases, especially in *pulmonary consumption*, *tubercular affections* in many parts of the body, and where it is desired to saturate the system quickly with iodine. It appears likely to play an important part in medicine. Fifteen to 30 grains of the hydriodic ether are transferred, by means of a graduated pipette, into a little ground-stoppered bottle (3 or 4 Cc.) 1 to 1½ inches high. The ether is covered with a stratum of water about 2 or 2½ Mm. thick, the object of which is to moderate the evaporation; when the vial is applied to one of the nostrils, and the air contained within it is drawn by an inspiration. The ethereal vapor is sufficiently diluted with air before reaching the lungs. The evaporation of the ether may be accelerated by inclining the vial to one side, so that the continuity of the watery layer may be broken, and the heat of the hand may be applied to the same object. Fifteen or 20 inspirations suffice for the impregnation of the system with iodine, and a quarter of an hour after the cessation of the inhalations, iodine is found in the urine; and has also been found present 50 or 60 hours afterward. Some prefer to have it in glass capsules, or "pearls," which hold 10 or 15 minims, and may be crushed in the handkerchief and inhaled.

ÆTHYLENI BICHLORIDUM.—ETHYLENE BICHLORIDE.

FORMULA: $C_2H_2Cl_2$. MOLECULAR WEIGHT: 98.68.

SYNONYMS: *Æthylum chloratum*, *Liquor Hollandicus*, *Elaylum chloratum*, *Dutch liquid*, *Ethene chloride*.

Source and History.—In 1795, four associated Dutch chemists discovered that when 1 measure of alcohol was mixed with 3 of sulphuric acid, and heat applied, a gas was evolved, named by them *olefant gas* (now known as ethylene or ethene), from its property of forming an oil-like liquid with chlorine. This

liquid, for many years recognized under the name *Dutch liquid*, is ethene chloride, or bichloride of ethylene.

Preparation.—To prepare it, connect a 32-ounce chemical flask, A (Fig. 12), furnished with a safety funnel, B, by means of glass tubes, with two 8-ounce wash bottles, C, C, one of which contains 4 fluid ounces of sulphuric acid, the other a like amount of solution of caustic potash. The second is connected, by means of a glass tube, with a glass percolator, D, covered with a sheet of rubber, through which the tube protrudes. The exit of the percolator is loosely inserted into the mouth of the bottle, E, which contains 4 fluid ounces of distilled water.

Fig. 12.

Connect the 16-ounce chemical flask, F, with an 8-ounce wash bottle, G, which contains 4 fluid ounces of distilled water, and is connected with the percolator, D, by means of the glass tube, H, protruding through the rubber cover. Into the flask, A, place a mixture of alcohol 2 fluid ounces, and sulphuric acid 12 fluid ounces; and into the flask, F, place 1 ounce of black oxide of manganese and 6 fluid ounces of hydrochloric acid, previously diluted with 4 fluid ounces of water. Apply heat now to the flask, A, by means of a spirit lamp, and, when the gas begins to flow, heat the flask, F; in like manner, and thus pass both gases (ethene and chlorine) simultaneously into the percolator, upon the sides of which an oily substance will form and trickle through the exit into, and settle to the bottom of, the distilled water. This is impure bichloride of ethylene, and must be agitated with water, then with sulphuric acid, and finally distilled. As the reaction progresses, the contents of the flask, A, may be slowly replenished, through the safety funnel, B, with a mixture of equal parts of sulphuric acid and alcohol. Finally, when the flow of gas ceases, or the reaction becomes irregular, suspend the operation, agitate the impure liquid collected in the bottle, E, with distilled water, then with sulphuric acid, and lastly distill it.

Bichloride of ethylene may also be prepared by the process of Limpricht (1856), who made it by passing olefiant gas through a retort half filled with a mixture of 2 parts of black oxide of manganese, 3 parts of common salt, 4 parts water, and 5 of sulphuric acid. The retort being gently heated at first with a single red-hot coal.

Description.—Bichloride of ethylene is a mobile liquid, colorless, inflammable, and possessed of a fragrant, ethereal odor, and a sweetish taste. It is very soluble in alcohol and ether, and only slightly so in water. Its specific gravity is 1.271 at 0° C. (32° F.), and its boiling point 85° C. (185° F.). Neither sulphuric acid nor hydrate of potassium affects it. Bichloride of ethyl must not be confounded with solution of ethyl chloride (C_2H_5Cl), or the so-called hydrochloric ether (see below).

Action and Medical Uses.—Bichloride of ethylene has been proposed as a much safer anæsthetic than chloroform, but it has not come into use on account of the excessive irritation of the throat and fauces attending its inhalation. It

is occasionally used locally, in spray or otherwise, to allay the sufferings in certain maladies, from pain, as in *rheumatism, lumbago, neuralgia*, etc. The anæsthetic dose is about that of chloroform.

Related Compounds.—**ETHYL CHLORIDE** (C_2H_5Cl), *Hydrochloric ether*, is made by passing dry hydrochloric acid gas into cold alcohol, and purifying the product by distilling the contents of the retort, washing the gas with a little tepid water, and condensing in a receiver surrounded with ice and salt. Ethyl chloride, or chloroethane, is a volatile, highly inflammable liquid, boiling at $12.5^\circ C.$ ($54.5^\circ F.$), and is, consequently, gaseous at ordinary temperatures. Water dissolves 10 per cent, and alcohol, at $21^\circ C.$ ($69.8^\circ F.$), dissolves 48.3 per cent of its weight. Ethyl chloride, or hydrochloric (or muriatic) ether, is occasionally employed in combination with an equal volume of alcohol, as a substitute for the compound spirit of ether, in doses of from 5 to 20 drops diluted with water, wine, etc. It has been used locally to anæsthetize parts in *minor operations*. It must not be used near a flame, and its inhalation may depress the heart.

CHLORIC ETHER, is a name once applied to mixtures of alcohol, and from 5 to 18 per cent of chloroform. Afterward, it was prepared by distilling chlorinated lime with water and an excess of alcohol. It is seldom mentioned at the present day, and has properly become almost obsolete.

ETHYLENE CHLORIDE, *Ethylidene chloride*, *Ethydene dichloride*, or *Monochlorinated hydrochloric ether* ($C_2H_4Cl_2$, or $CH_2,CHCl_2$). Specific gravity 1.198. Boiling point $57.5^\circ C.$ ($135.5^\circ F.$). This compound, isomeric with bichloride of ethylene, is produced by acting upon ethyl chloride (see above) with chlorine, avoiding an excess of the latter. It has been tried as an anæsthetic, and though so far as physiological experiments go to show it is safer than chloroform, clinical evidence does not harmonize with that of the physiological investigators, and consequently its use as an anæsthetic has been practically abandoned on account of the number of deaths occasioned by it. According to Brunton, its action upon the cardiac ventricles is precisely like that of chloroform. It is now generally accepted as being more dangerous than the latter.

AGAVE VIRGINICA.—FALSE ALOE.

The root of *Agave Virginica*, Linné.

Nat. Ord.—Amaryllidaceæ.

COMMON NAMES: *False aloe*, *Rattlesnake's master*.

Botanical Source.—A perennial, herbaceous, stemless plant, with a premorse, tuberous root. Leaves linear-lanceolate, fleshy, glabrous, and radical, with cartilaginous, marginal serratures. The scape, which is round, and from 3 to 6 feet high, bears sessile, greenish-yellow flowers, scattered in a wand-like spike, emitting a strong fragrance. The root (the part employed) is very bitter, and yields its properties to alcohol and water by infusion.

History.—This plant is common to Pennsylvania and the Southern States, growing on dry or rocky banks, and flowering in August and September. In some parts of the country this plant is considered a valuable antidote to wounds by poisonous snakes, and is termed "rattlesnake's master."

Action and Medical Uses.—False aloe is reputed laxative and carminative, and has been beneficially employed in *obstinate diarrhœa, flatulency, spasm of the intestines*, etc.

Related Species.—*Agave Americana*, Linné. *American aloe*. Nat. Ord.—Amaryllidaceæ. Tropical America; naturalized in Florida. Cultivated for centuries in Mexico (A. De Candolle). *American aloe*, *Magney* or *Mel*, also called *Century plant*, from an erroneous supposition that it blossoms only once in a hundred years, is the largest of all herbaceous plants; it inhabits the warmer latitudes of the American continent, where it flourishes as an evergreen, and is utilized for hedges in southern Europe, where it is known as aloe. The agaves, from their resemblance to the aloe family, have been called aloes, as false aloe and American aloe; but the agaves differ from the aloe in having entirely different properties, both chemical and medicinal, and also in the relation of the botanical parts, the ovary of the latter being superior; that of the agave, inferior. All agaves are natives of Mexico. The aloe, on the contrary, is an Eastern plant. The leaves of the American aloe are long (4 to 6 feet), lanceolate, thick, succulent, and curved or reflected backward, and beset with marginal and terminal spines. The flowering scape may reach a height of from 20 to 40 feet, the plant blooming in its native habitat about once in a decade.

The *Agave Americana* and other species, particularly *A. pulqué*, are employed in Mexico in the manufacture of a spiritous beverage known as *pulqué*. This is prepared by fermentation of the saccharine liquid, known as *aguamiel* (honey water), which exudes from the leaves and root when cut. Occasionally this "honey water" is evaporated to a honey-like, or syrupy consistence, and may be resolved into sugar. *Distilled pulqué* is a brandy-like liquor called *mescal*. The fibres of the leaves are made into thread and cordage, and are known as *pita*.

Gum maguey is analogous to gum arabic, though differing in the amount of calcium salts contained therein. It is partially soluble, the portion dissolving resembling arabin. The insoluble portion resembles bassorin. The pulp of the leaves, locally applied, acts as a rubefacient, somewhat like mustard. The fresh juice is said to act upon the kidneys and bowels, and also to promote menstruation. Dr. G. Perrin considers it a superior remedy in *scorbutus*, preferring it to lime juice, in doses as high as 2 fluid ounces 3 times a day (*N. Y. Jour. Med. N. S. VII.*, 181).

Agave mexicana, Lamarck; and *Agave vivipara*, Linné. These two species are closely related to the preceding plants, and are natives of Mexico.

AGRIMONIA.—AGRIMONY.

The whole plant of *Agrimonia Eupatoria*, Linné.

Nat. Ord.—Rosaceæ.

COMMON NAMES: *Agrimony*, *Cockleburrr*, *Stickwort*.

Botanical Source and Description.—Agrimony is a perennial herb, growing to the height of 2 or 3 feet, having stems but little branched, and covered with a soft, silky pubescence. The leaves are alternate, long, nearly smooth beneath, interruptedly pinnate, having from 3 to 5 or 7 oblong-ovate, coarsely serrated leaflets, between which are interspersed several smaller ones. The root is long, fibrous, and tapering, and of a reddish-brown color. It is much branched at the summit, producing numerous heads. The flowers are small, yellow, and borne in a dense, racemose spike, from a half to 1 foot long. The calyx-tube is curiously fluted with 10 ribs, conical, and surmounted with reddish, hooked bristles. Agrimony has a bitterish, harsh, subastringent taste, which is somewhat aromatic, but unpleasant. This taste is strongest in the root. Its odor is aromatic, and especially is it more fragrant when in bloom.

History and Chemical Composition.—Agrimony is common in the United States and Canada, as well as in Europe and Asia. It thrives along roadsides, in old fields, and in woodlands, flowering from midsummer through September. The burrs attach themselves to the clothing as one comes in contact with them, hence the common names, cockle-burr and stickwort. It is employed in domestic practice on the continent as a gargle. The aborigines and Canadians used the root in the treatment of intermittent febrile states. According to Linneus, a grateful beverage was prepared by steeping the plant in whey. Porcher states that an infusion of the leaves and stalks, previously treated with a weak bismuth solution, permanently dyes wool a beautiful, golden color, and that tanners employed the flowers in preparing soft and delicate hides. French peasants use it as a substitute for tea. Agrimony yields its properties to water and alcohol. Tannin and a volatile oil are the only known chemical constituents, the latter being obtained by distillation.

Action, Medical Uses, and Dosage.—Agrimony is a mild tonic, alterative, and astringent. A decoction of it is highly recommended in *bowel complaints*, *leucorrhæa*, *chronic mucous diseases*, *chronic affections of the digestive organs*, *profuse bleedings*, of an asthenic character, certain *cutaneous diseases*, *icterus*, etc. A strong decoction, sweetened with honey, is reputed curative in *scrofula*, if its use be persisted in for a length of time; and it has also been highly extolled in the treatment of *gravel*, *asthma*, *coughs*, and *obstructed menstruation*. Dr. D. C. Payne speaks highly of a continued use of a decoction of this plant in the treatment of *erysipelas* and *scrofulous affections*, to be used freely, in connection with diet and regularity of the bowels. It is also reputed to be valuable as a diuretic, and has been considered a specific in *dropsy* and in *gonorrhæa*. As a gargle, the decoction is useful in *ulcerations of the mouth and throat*. The astringency of the root renders it very useful in those affections requiring the exhibition of astringents.

Specifically, agrimony checks mucous profluvia, and gives tone to mucous tissues. *Chronic bronchitis*, *phthisis*, with increased secretions, and muddy, ill-smelling urine, *humoral asthma*, and *chronic genito-urinary catarrhal states*, are most benefited by it. Pain in the lumbar region is relieved by it. *Cystitis*, *nephritis*,

Fig. 13.

Agrimonia.

and an irritable condition of the bladder, are met by it, as is painful *renal congestion*. Dose: A drachm or two of the pulverized leaves may be taken for a dose, or 2 or 3 fluid ounces of the decoction; specific agrimonia, 1 to 60 drops.

Specific Indications and Uses.—Deep-seated and colicky pain in the lumbar region, with uneasy sensations reaching from the kidneys to the hips and umbilicus (renal colic); muddy, ill-smelling urine, and dirty looking skin; especially as a palliative in phthisis; cystic catarrh; cough, with profuse, thick secretions, and pain under the lower ribs, extending to the renal organs; renal congestion; cough, with dribbling or expulsion of urine; irritation of kidneys or urinary organs, with cough.

Related Species.—*Agrimonia parviflora*, Aiton. *Small-flowered, or Sweet-scented agrimonia*. United States; Pennsylvania, southward and westward. Stronger scented than common agrimonia; has smaller flowers, and from 11 to 19 pairs of densely crowded leaflets, with smaller ones interspersed. Has numerous resinous dots on the leaves, rendering it somewhat clammy.

Alchemilla vulgaris, Ladies' mantle. Europe. An astringent, bitterish herb, once much used in *diarrhoea*. Accredited by the ancient alchemists with wonderful powers.

AILANTHUS.—AILANTHUS.

The inner bark of the tree and root of *Ailanthus glandulosa*, Desfontaines.

Nat. Ord.—Simarubaceæ.

COMMON NAMES: *Tree of Heaven, Ailanto, Chinese sumach.*

Botanical Source.—*Ailanthus* is a large tree, with blunt, clumsy branches, which give to it an odd appearance after the leaves have fallen. The leaves are odd-pinnate, each consisting of from 10 to 20 pairs of leaflets and a terminal one. The leaflets are about 2 inches long, ovate, smooth, acute, and have a few blunt, glandular teeth at the base (hence, the specific name, *glandulosa*). The flowers are small, green, and collected in large terminal panicles. They are polygamous, or generally dioecious. The calyx consists of 5 united sepals. The petals are 5, small, green, and longer than the sepals. The stamens are 10 in the male flowers, but fewer in the female. The pistil is surrounded at the base by a disk, and consists of from 3 to 5, 1-ovuled, free carpels, with united styles. The fruit is a flat, membranous samara, bearing a seed in the middle, and somewhat resembling the fruit of the ash.

History, Description, and Chemical Composition.—*Ailanthus glandulosa* is a native of China, where it is known as "Ailanto," of which the German name "Götterbaum" is said to be a translation. "Tree of Heaven" is the name by which the tree is vulgarly known in this country. It is in common cultivation as a shade tree throughout Europe and the United States, and has become naturalized in many localities. It was formerly classified in the natural order, *Rutaceæ*, but is now placed in that of *Simarubaceæ*. It is allied to the genera, *Quassia* and *Simaruba*, from which it differs in the fruit being a samara.

This tree is of rapid growth, and easily accommodates itself to any soil, thus being well adapted to cultivation; but it is objectionable on account of a fetid odor, which is mostly exhaled from the sterile flowers. The genus *Ailanthus* consists of 4 species, all large trees, and natives of Asia, none of which, however, are cultivated in this country excepting the *A. glandulosa*. The recent root is white, hard and woody. It is covered with a white, fibrous bark, the outer part of which is gritty, brittle, and yellowish, over which is a gray epidermis. The epidermis of the limbs and growing sprouts is smooth, shiny and brown, or yellowish. It is studded with numerous little eruptions which increase in size with age, until, when old, the bark is rough. Beneath this a green coloring matter is found in young specimens, while the bark next to the wood is white. In growing shoots the woody matter is thin, surrounding a yellowish-brown pith, which latter decreases in proportion with the growth of the shrub. Both the root and shrub have an acid reaction when fresh, and exhale a disagreeable odor when broken. For medicinal purposes, the bark of the small bushes and roots is to be preferred. Prof. Hetet, of Toulon, noticed the tree in the *Journal de Pharmacie*, in 1859, at which time it attracted attention in France, in consequence of its leaves having been suggested as food for a species of silk-worm. The

bark of the tree was experimented with, and attracted some attention at that time as an emeto-cathartic and anthelmintic, but it seems to have quickly fallen into disuse.

In the year 1875, Dr. H. L. True published an article in the *E. M. Journal*, which revived, among the Eclectic practitioners of this country, an interest in the therapeutical uses of the bark; since which numerous communications to medical journals have created a demand for it, the bark being supplied in abundance in most localities. In the later fifties, M. Payen analyzed the bark, and detected lignin, chlorophyll, yellow coloring matter, pectin, bitter substance, aromatic resin, traces of volatile oil, nitrogenous matter, and some salts. Afterward (1861), Mr. Alonzo Lilly, Jr., made an examination, the result of which differs considerably from the above, as, according to this gentleman, the constituents are, starch, tannin, albumen, gum, sugar, oleoresin, and a trace of volatile oil, potash, phosphoric acid, sulphuric acid, iron, lime, and magnesia.

The bark has a nauseating, bitter taste, and when recent, a sickening odor. Both the fresh and the carefully dried bark impart a deep-green color to alcohol, probably due to chlorophyll, the color gradually changing to yellowish-brown by age, the action of light accelerating the change. According to our experience, the bark contains a resinous substance, which, with the volatile oil, is extracted by alcohol, which agent will perfectly exhaust all the characteristic properties of either the fresh or dry ailanthus. According to the experiments of M. Hetet, the purgative property resides in the resin, while the volatile oil gives rise to the prostrating and other ill effects produced on those exposed to the vapors of the evaporating extract; and, probably, to a similar hydrocarbon, may be ascribed the sickening sensation experienced by many persons when inhaling the atmosphere vitiated by the emanations from an Ailanthus tree in blossom. M. Hetet's statement, that the resin is purgative, has been disputed; some even assert that the resin is inert.

Action, Medical Uses, and Dosage.—The bark of ailanthus has been employed by Roberts, Dugat, and others, both in the recent and dried state, as a remedy for *dysentery* and *diarrhœa*; also in *gonorrhœa*, *leucorrhœa*, *prolapsus ani*, etc. Fifty grammes of the root-bark are infused for a short time in 75 grammes of hot water, then strained, and when cold, administered in teaspoonful doses, night and morning. To lessen the disagreeable impression following its use, as well as to mask its bitterness, it may be administered in sweetened orange-flower water, or in some other aromatic. Professor Hetet, of the Toulon Naval School, states in *Jour. de Chim. Med.*, December, 1859, that the leaves and bark, in powder, or in the form of an aqueous or of an alcoholic extract, will remove *tapeworm*; but he found its action upon patients to be very disagreeable and nauseating, somewhat like that occasioned by tobacco upon young smokers. Dupuis has also found it useful as a *tœnifuge*. In the September number of the *Eclectic Medical Journal*, for 1875, p. 393, Dr. H. L. True, of Ohio, states, that from his observations, the bark is not poisonous, but produces vomiting, great relaxation, and a death-like sickness, which symptoms gradually pass away. He has successfully employed a tincture of the root-bark in *cardiac palpitation*, *obstinate singultus*, *asthma*, and *epilepsy*. Its use in epilepsy has gained in reputation. It should be studied for its action in sick and nervous *headache*, with nausea, and an indescribable burning sensation in the forehead. Webster states, "the remedy, in 2x dilution, will cure *malignant sore throat*, *ulcerated tonsils*, and other *tonsillar inflammations*, marked by *adynamia* and *persistence*." He states that he has been pleased with it in *putrid*, *malignant*, *typhoid scarlatina*, with dusky, carmine eruption, high temperature, pungent surface, pulse small and extremely rapid, with thirst, delirium, and coma. The tongue is dusky, parched, and fissured; sordes upon the teeth; and the urine discharges involuntarily. Dose, 1 to 10 drops of the 2x dilution. His uses of the drug were derived from homœopathy. Dr. True considers the presence of these trees in malarial districts to have a strong action, similar to that of the eucalyptus, in antagonizing those influences that produce *intermittents*. The dose of the tincture is from 5 to 60 drops, repeated as often as required, or, from 2 to 4 times a day; specific ailanthus, 5 to 20 drops.

Specific Indications and Uses.—Cardiac palpitation; spasmodic or epileptiform muscular contraction.

Related Species.—*Ailanthus excelsa*, Roxburgh. Bark used in India as a powerful febrifuge, tonic and stomachic, being used in decoction in *dyspepsia*. Leaves and bark in good repute as a tonic after labor, and the juice of the leaves and fresh bark employed by the Concans as a remedy for after-pains (Dymock). Daji found in it *ailanthic acid*, a reddish-brown, deliquescent mass, bitter, soluble in water, less so in ether and alcohol; insoluble in benzol and chloroform.

Ailanthus malabarica, De Candolle. Habitat, Canara. Yields a fragrant resin called "mutteepal," which is powdered and administered in small doses, in milk, for *dysentery* and *bronchitis*. It is also employed as incense. The bark is tonic, febrifuge, and valued in *dyspepsia* (Dymock).

ALCOHOL.—ALCOHOL.

FORMULA (Absolute, or ethyl alcohol): C_2H_5OH . **MOLECULAR WEIGHT**: 45.9.

SYNONYMS: *Ethyl alcohol*, *Ethylic alcohol*, *Ethyl hydroxide*, *Alcohol*, *Alcohol vini*, *Rectified spirit*, *Spiritus rectificatus*, *Vinic alcohol*; *Spirit of wine*.

Official Kinds.—I. **ALCOHOL ABSOLUTUM** (U. S. P.), *Absolute alcohol*. "Ethyl alcohol, containing not more than 1 per cent, by weight, of water"—(U. S. P.).

II. **ALCOHOL** (U. S. P.)—*Alcohol*. "A liquid composed of about 91 per cent, by weight, or 94 per cent, by volume, of ethyl alcohol ($C_2H_5OH=45.9$), and about 9 per cent, by weight, of water"—(U. S. P.).

III. **ALCOHOL DILUTUM** (U. S. P.)—*Diluted alcohol*. "A liquid composed of about 41 per cent, by weight, or about 48.6 per cent, by volume, of absolute ethyl alcohol ($C_2H_5OH=45.9$), and about 59 per cent, by weight, of water"—(U. S. P.).

IV. **ALCOHOL DEODORATUM** (U. S. P.)—*Deodorized alcohol*. "A liquid composed of about 92.5 per cent, by weight, or 95.1 per cent, by volume, of ethyl alcohol ($C_2H_5OH=45.9$), and about 7.5 per cent, by weight, of water"—(U. S. P.).

The foregoing "should be kept in well-closed vessels, in a cool place, remote from lights or fire"—(U. S. P.).

History and Source.—The Bible frequently mentions fermented juices from various fruits, as the grape or pomegranate. However, the art of abstracting the alcohol from alcoholic beverages by distillation, was, in all probability, discovered by the Arabs in the ninth, or later centuries. The raw materials used in the making of alcohol by distillation, may be taken from three sources: 1. Alcoholic liquids which have already undergone fermentation, *e. g.*, wine, beer, cider. 2. Saccharine material which exists, for example, in sugar cane, or grape juice; from this, alcohol is generated by fermentation. 3. Starch-bearing material, of which an innumerable variety is available for this purpose, *e. g.*, root tubers, such as potatoes, and such cereals as rye, corn, barley, wheat, rice, etc. With this class of material, the conversion of starch into fermentable sugars (maltose, or dextrose), is effected in the so-called mashing process, whereby the starchy material, after preparatory treatment, is acted upon by an infusion of malt, the active principle of which, *diastase*, converts starches into maltose and dextrin, at temperatures not to exceed $70^{\circ}C$. ($158^{\circ}F$). In rare cases, perhaps, the starch is converted into dextrose (glucose) by treatment with dilute sulphuric acid, at a temperature near the boiling point of water.

Vinous, or Alcoholic Fermentation.—Fermentation, generally speaking, is a process of decomposition of more or less complex organic substances into simpler compounds, induced by the vegetative action of exceedingly small, living organisms, called ferments (to which belong, *e. g.*, the yeast plants and bacilli). The action of purely chemical ferments, called enzymes, as, *e. g.*, diastase in malt, or myrosin in black mustard seeds, etc., is analogous to, though not identical with, fermentation. Accordingly, we speak familiarly of acetic, lactic, butyric, putrid fermentation, etc. In the vinous fermentation, a solution of sugar, *e. g.*, dextrose, is decomposed into alcohol and carbonic acid gas, under the influence of the yeast plant, of which there are several species, the most prominent of which is *Saccharomyces (Torula) cerevisiæ*. Dextrose, for example, is decomposed as follows: $C_6H_{12}O_6=2C_2H_5O+2CO_2$. This formula, however, illustrates the process only in a general way, as various circumstances tend to alter the above reaction. Pasteur has found among the products of vinous fermentation, about 0.6 per cent of succinic acid and 3 per cent of glycerin, as regular constituents. The most favorable temperature at which fermentation takes place, is from 15.5° to $32.2^{\circ}C$.

(60° to 90° F.); at temperatures somewhat higher than 30° C. (86° F.), butyric and other kinds of fermentation are liable to set in. Not all sugars are directly fermentable. Cane sugar, for example, under the influence of yeast, first becomes converted into fermentable invert sugar (an equi-molecular mixture of *lævulose* and *dextrose*).

The part played by the yeast cells has not yet been completely elucidated, notwithstanding the advances made in this direction through the famous researches of Pasteur, Liebig, Naegeli, and others. Some contend that fermentation is purely physiological, others, that it is a physical, and others again, that it is an essentially chemical process. Quite recently, E. Buchner demonstrated that a fluid obtained by expressing, under high temperature, moistened yeast, previously dried by strong pressure, is capable of producing fermentation.

Preparation.—The bulk of commercial alcohol is, at the present day, derived from cereals and potatoes; in Germany, principally from the latter source. If potatoes are the raw material used, they are first steamed in suitable, ingeniously devised vessels, in order to gelatinize the starch grains. After cooling the mass to a temperature of about 65.5° C. (150° F.), it is subjected to the process of mashing, in large vats with steam fittings, by mixing the mushy material with finely comminuted malt, whereby, under the influence of the malt diastase, starch is converted into maltose and dextrin, the latter being subsequently converted into maltose by prolonged action. Then the temperature is reduced to 21.1° C. (70° F.), and yeast is added, which starts the fermentation. Cereals are treated either in the same manner, or are merely crushed without being steamed, and are then subjected to the same treatment.

The fermented mass contains, of *non-volatile matters*, fibers and husks, inorganic salts, protein bodies, peptones, fat, yeast, lactic and succinic acids; of *volatile matters*, alcohol, fusel oils, and traces of fatty acids, *e.g.*, acetic acid, but not the higher acids, such as butyric, if the fermentative process was properly conducted. The alcohol may then be separated from the mash by fractional distillation in a simple copper still with worm condenser, the distillate being repeatedly distilled or *rectified*, in order to get a stronger product. This process is still in use in the making of Irish whiskies. In recent times this rather primitive procedure has been replaced by the introduction of ingeniously contrived stills, especially the so-called column-stills, the construction of which has reached such a state of perfection that it is possible to obtain, with some of these, a strong alcohol of 94 per cent, by direct distilling from the fermented mash in a single operation; the higher alcohols, as fusel oil, remaining behind for the most part. (For details see Sadtler, *Indust. Org. Chem.*, 1895.) The alcohol resulting from the first distillation, unless obtained at once pure and of the desired strength by the use of the perfected stills aforementioned, must be subjected to redistillation, called *rectification*. As it is extremely difficult, however, to completely remove by fractional distillation certain impurities, especially the higher alcohols, propyl, isobutyl, and the amyl alcohols, collectively called *fusel oils* or *grain oils*, it has been found advisable to purify the raw spirit prior to rectification. This has been tried more or less successfully by chemical means, employing oxidizing agents, as ozone, or silver nitrate; but a rather expedient and efficient method seems to be to dilute the spirit to a strength of about 50 per cent, whereby the fusel oil is thrown out as an insoluble layer; the spirit is then filtered through charcoal, and rectified (see Sadtler). Another efficient method is said to consist in distilling the spirit over fused acetate of sodium, employed in the quantity of 2 per cent. Another method, which seems promising, is to shake out the fusel oils from the dilute spirit with mineral oils (Bang and Rufin).

Commercial Forms.—*Absolute alcohol.* Mere rectification will not produce a liquid stronger than about 94 per cent, by volume. The remaining 6 per cent of water must be removed by chemical means; which is best accomplished by allowing the alcohol to stand over freshly prepared, unslacked lime, for several hours, then distilling from a water-bath, a process which should be repeatedly carried out. It is often preferred to boil the alcohol with unslacked lime for one hour, using a reflux condenser, and then distilling off the alcohol. This process, however, is attended with some danger if the alcohol has more than 5 per cent of

water. Dehydrated chloride of calcium has also been used in preparing ~~the~~ alcohol.

Alcohol of the U. S. P. contains 91 per cent, by weight, or 94 per cent, by volume, of pure ethyl alcohol, and has a specific gravity of 0.820 at 15.6° C. (60° F.). This strength is obtained in the process of redistillation or rectification.

ARDENT SPIRITOUS BEVERAGES.—*Holland gin*, is obtained by distilling grain spirit with juniper berries.

Rum, is made in the West Indies by fermentation and subsequent distillation of molasses derived from the sugar cane.

Arrack, is the distilled product of the fermented juice of the palm tree, in Batavia, or is obtained from rice and millet, in China, by malting, fermenting, and distilling.

Brandy, is the product of distillation of wines, or the fermented juices from such fruits as the apple or pear, called cider and perry.

Genuine cognac, is a fine grade of brandy, the product of distillation of French wines. Its characteristic aroma is due to the presence of cenanthic ether (oil of wine).

American whiskey, is prepared from malted corn and rye; either mixed grains are used (Kentucky bourbon), or malted rye alone (Pennsylvania whiskeys).

Irish whiskeys, have a smoky flavor, due to the peat fuel used in the making of the malt.

Description and Tests.—I. **ALCOHOL ABSOLUTUM (U. S. P.)**, *Absolute alcohol*, *Anhydrous alcohol*, *Ethyl alcohol*. Pure absolute alcohol is "a transparent, colorless, mobile, and volatile liquid, of a characteristic, rather agreeable odor, and a burning taste. Very hygroscopic. Specific gravity not higher than 0.797 at 15° C. (59° F.); or 0.789 at 25° C. (77° F.). In other respects, absolute alcohol has the properties, and should respond to the reactions and tests, of deodorized alcohol (see *Alcohol Deodoratum*)"—(U. S. P.).

It boils at 78.3° C. (174° F.), and assumes an oleaginous consistence at -90° C. (-130° F.). It is very combustible, burning with a pale-blue flame, without smoke or residue, giving out a very intense heat, and producing carbonic acid gas and water. Chloride of sodium added to it will render its flame yellow; chloride of potassium, whitish violet; boric acid, or a salt of copper, green; chloride of lithium, carmine red; chloride of strontium, crimson; and chloride of barium, greenish-yellow. A solution of barium hydrate in absolute alcohol, detects traces of water in absolute alcohol by yielding a precipitate when mixed with it. Dehydrated copper sulphate, which is white, turns blue with absolute alcohol when water is present. It mixes in all proportions with water, wood-spirit, and ether; heat is evolved when it is added to water, and contraction of volume takes place, which amounts to nearly 4 per cent when 53.9 parts of alcohol, and 49.8 parts of water, are mixed, resulting in a volume of 100 parts, instead of 103.7 parts. One part of ether added to 2 parts of alcohol, forms with $\frac{1}{10}$ part of oil of wine, *Hoffman's Anodyne Liquor*. Partly on account of its affinity for water, it preserves animal and vegetable tissues. It dissolves hydroxide of potassium and of sodium, certain metallic chlorides and bromides, the organic acids, camphor, volatile oils, iodine, urea, resins, balsams, etc. With nearly all acids it produces the compound ethers. Most oxygen salts with inorganic acids, excepting calcium and magnesium nitrates, starch, caoutchouc, the protein compounds, etc., are insoluble in it. Of the fixed oils, castor oil is the most freely dissolved by it. It combines with many neutral metallic chlorides, as of magnesium, calcium, manganese, etc., taking, in these compounds, the place of water of crystallization. Sulphur and phosphorus are dissolved by it to a limited extent. Dry chromic acid introduced into a mixture of air and alcoholic vapor, causes an explosion. If a spiral piece of platinum wire be placed upon the wick of an alcohol lamp, and the flame be suddenly blown out, the platinum wire will continue to glow with a white heat, caused by the imperfect combustion of the alcoholic vapors.

II. **ALCOHOL (U. S. P.)—Alcohol**. The alcohol of commerce possesses the above qualities (see *Absolute Alcohol*) in proportion to its freedom from water, as known by its specific gravity. The strength of alcoholic fluids, the sole ingredients of which are alcohol and water, is determined in the spirit trade, under the supervision of the U. S. Government, by taking the specific gravity by means of

hydrometers, also observing the temperature at which the specific gravity is taken. By the aid of tables, the actual percentage of the spirit, by volume, is then ascertained. *Proof spirit*, as defined by the U. S. Revenue Office, is a liquid containing 50 volumes of absolute ethyl alcohol in 100 volumes of spirits, this solution being called 100 per cent *proof spirit*. Its specific gravity is 0.9343 at 15.6° C. (60° F.). If higher, the spirit is below proof; if lower, the spirit is over proof. It is used in pharmacy to form tinctures, extracts, etc. The Pharmacopœia gives the following description and tests: "A transparent, colorless, mobile, and volatile liquid, of a characteristic, rather agreeable odor, and a burning taste. Specific gravity about 0.820 at 15° C. (59° F.); or 0.812 at 25° C. (77° F.). Miscible with water in all proportions, and without any trace of cloudiness; also miscible with ether or chloroform. It is readily volatilized, even at low temperatures, and boils at 78° C. (172.4° F.). It is inflammable and burns with a blue flame. It should not affect the color of blue or red litmus paper previously moistened with water. If 50 Cc. of alcohol be evaporated in a clean glass vessel, no color or weighable residue should remain. On allowing alcohol, mixed with one-third of its volume of water, to evaporate spontaneously from clean, odorless blotting-paper saturated with it, no odor of fusel oil, nor other foreign odor, should become perceptible. If 10 Cc. of alcohol be mixed in a test-tube with 5 Cc. of potassium hydrate T.S., the liquid should not at once become dark-colored (absence of aldehyde, methyl alcohol, or oak tannin). If 20 Cc. of alcohol be shaken in a clean, glass-stoppered vial with 1 Cc. of silver nitrate T.S., the mixture should not become more than faintly opalescent, or acquire more than a faint brownish tint, when standing during six hours in diffused daylight (limit of organic impurities, amylic alcohol, etc.)."—(U. S. P.).

III. **ALCOHOL DILUTUM (U. S. P.)**.—*Diluted Alcohol*. "Alcohol, five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 M]; distilled water, five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 M]. Mix them. If the two liquids be measured at the temperature of 15.6° C. (60° F.), the mixture, when cooled to the same temperature, will measure about 971 Cc. Diluted alcohol may also be prepared in the following manner: Alcohol, four hundred and ten grammes (410 Gm.) [14 ozs. av., 202 grs.]; distilled water, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]. Mix them. Diluted alcohol has a specific gravity of about 0.936 at 15° C. (59° F.), about 0.937 at 15.6° C. (60° F.), and about 0.930 at 25° C. (77° F.). It should respond to the reactions and tests given under *Alcohol*"—(U. S. P.).

IV. **ALCOHOL DEODORATUM (U. S. P.)**.—*Deodorized alcohol*. "Specific gravity about 0.816 at 15° C. (59° F.), or 0.808 at 25° C. (77° F.). If 25 Cc. of deodorized alcohol be mixed with an equal volume of water and 5 Cc. of glycerin, and the mixture allowed to evaporate spontaneously from a piece of clean, odorless blotting-paper, no foreign odor should become perceptible when the last traces of the alcohol leave the paper (absence of fusel oil constituents). If 25 Cc. be allowed to evaporate spontaneously in a porcelain capsule carefully protected from dust, until only a moisture is left, no red or brown color should be produced upon the addition of a few drops of colorless, concentrated sulphuric acid (absence of amylic alcohol, non-volatile, carbonizable, organic impurities, etc.). In other respects, deodorized alcohol has the properties, and should respond to the reactions and tests, of *Alcohol*"—(U. S. P.).

"Rules for making an alcohol of any required lower percentage, from an alcohol of any given higher percentage:

I. **BY VOLUME**.—Designate the volume-percentage of the stronger alcohol by *V*, and that of the weaker alcohol by *v*.

Rule.—Mix *v* volumes of the stronger alcohol with pure water to make *V* volumes of product. Allow the mixture to stand until full contraction has taken place, and until it has cooled, then make up any deficiency in the *V* volumes by adding more water.

Example.—An alcohol, of 30 per cent by volume, is to be made from an alcohol of 94 per cent by volume.—Take 30 volumes of the 94 per cent alcohol, and add enough pure water to produce 94 volumes.

II. **BY WEIGHT**.—Designate the weight-percentage of the stronger alcohol by *W*, and that of the weaker by *w*.

Rule.—Mix *w* parts, by weight, of the stronger alcohol with pure water to make *W* parts, by weight, of product.

Example.—An alcohol of 50 per cent, by weight, is to be made from an alcohol of 91 per cent, by weight.—Take 50 parts, by weight, of the 91 per cent alcohol, and add enough pure water to produce 91 parts by weight"—(*U. & P.*).

Uses in Pharmacy and the Arts.—In the numerous official pharmaceutical preparations, alcohol, of various strengths, is a prominent constituent. Pharmacists also employ it as a fuel producing a high temperature during combustion without depositing soot upon bodies introduced into its flame. It is largely used in the arts as a solvent and preservative.

Action and Toxicology.—Applied locally to the skin, alcohol first causes a cooling sensation, but if evaporation be prevented, heat and irritation follow, and inflammation may result if too long applied. The skin and the mucous membranes are hardened by it, and the latter corrugated, owing to its coagulating power over albumen, and the abstraction of water from the tissues. Some fat is also removed from the integuments. As it at first constricts the arterioles, it may act slightly as an anæsthetic. Taken into the stomach in small amounts, (usually of the various liquors) it augments the appetite and increases digestive power. Owing to dilatation of the arterioles, slight congestion of the mucous tissues takes place, and the buccal and gastric secretions are increased, but if continuously imbibed, this excessive secretion results in catarrhal conditions, and, continuing, may produce atrophy of the gastric glands and hyperplasia of the gastric connective tissue. Furthermore, pepsin is precipitated by it, allowing digestive impairment through the loss of that ferment. The inordinate outpouring of gastric mucus (gastric catarrh) causes fermentation of the fatty, starchy, and saccharine foods, resulting in sour stomach, heart-burn, pyrosis, and that peculiar retching and morning vomiting of the drunkard.

Alcohol is believed to enter the blood before reaching the duodenum, and in that fluid it diffuses itself with great rapidity. The portal circulation is impressed, and greater hepatic activity follows, but finally, this overstimulation leads to destruction of the liver cells, fatty and atrophic alterations taking place, while the connective tissue is increased. This hyperplasia, with consequent shrinkage of the cells, allowing contraction of the connective tissues, results in that shrunken, hardened, and nodular state of the organ, known as *cirrhosis*. These liver changes take place more rapidly than those of the stomach. Alcohol in small doses increases the heart's action and surface circulation; all the body functions are stimulated and better performed, and temperature is slightly elevated. Larger doses produce exhilaration and vascular excitement, and a mild intoxication. Still larger doses affect muscular power, causing incoördination of movement (staggering), and the victim speaks incoherently and in a rambling manner—all the well-known phenomena of *drunkenness*.

Upon the nervous system, the first effects are increased cerebral activity, rendering the senses more acute, and all the mental actions more energetic. These effects are shared in common with the increased functional activity of the economy in general. In an exposed brain, turgescence and throbbing vessels have been observed as the effects of its first action, with dilatation of the vessels, and passive congestion as the secondary phase (Jacobi). In toxic amounts, cerebration is suspended, and profound insensibility takes place; there is a feeble performance of the body functions, and the movement centers are poisonously impressed, resulting in complete muscular inactivity, stertorous respiration, and arrest of breathing and the heart's action.

In large quantities, and continued daily, alcoholic liquors occasion intoxication, nervous derangement, loss of appetite, mental imbecility, dyspepsia, indurated liver, granular disease of the kidneys, paralysis, mania, atheroma of the vessels, apoplexy, and death. The alcohol is absorbed, and may be detected in the blood, urine, breath, brain, liver, and other organs, producing permanent injury to them. The treatment of acute alcoholic poisoning consists in emptying the stomach by means of the stomach-pump, and cautiously applying ammonia gas to the nostrils; external warmth should be used, cold water applied to the head, and faradism employed to stimulate respiratory action. It is extremely difficult to differentiate acute alcoholic poisoning from apoplexy,

opium poisoning, cerebral concussions, and hemorrhage into the brain tissues. The pupil may be contracted or dilated; unequal dilatation, however, is somewhat of a guide to intracranial hemorrhages. The odor of the breath will assist somewhat, but can not be relied upon, as alcoholic drinking is so common that any of these conditions may take place after one has imbibed an insufficient amount of alcohol to produce toxic symptoms. A person "dead drunk" should be treated as if poisoned, and not allowed to "sleep off" the effects.

After death from acute alcoholism, the gastric membranes are found intensely hyperemic, as are the meninges of the brain. The subarachnoid spaces, and the cerebral ventricles, are filled with an effusion of serous fluid; and the right ventricle of the heart, and the great veins, are distended with blood. From chronic poisoning, hyperplasia of the connective tissue, as thickening of the stomach walls, cirrhotic liver, and fatty heart, and hardened and contracted, or fatty, kidneys as well as atheromatous vessels and sclerosed nervous structures, are found. Taken into the system in moderate amounts (1 to 1½ ounces of absolute alcohol) alcohol is scarcely eliminated, but is destroyed by oxidation in the system, and imparts circulatory, nervous, glandular, and muscular force. It refreshes the exhausted system by yielding to it a force to be applied in the body functions, and in this way acts as food, though it is not known to contribute to the building of a single cell or fibre of the animal structures. It also acts as food, in that it retards or checks tissue waste by partially preventing the excretion of carbon dioxide and nitrogenous material; and it even favors the formation of fatty tissues, as is shown by its pathological tendency to cause depositions of fat in certain organs. That the temperature is increased by moderate amounts is well known, as is the fact that large doses depress the temperature; and this depression is more pronounced if fever be present. It may be concluded that alcohol serves as food, when it is used short of gastric impairment, does not over-stimulate, and is not in excess of what can be burned in the oxidation processes of the organism. In quantities in excess of those above mentioned, it is excreted by the lungs, skin, kidneys, etc.

Contrary to popular notions, alcohol does not protect one from the influence of cold, as has been shown by the experience of Arctic explorers, and by the ease with which drunkards are frozen to death. Nor does it protect one from the effects of the heat. The facility with which toppers are attacked with, and succumb to, epidemic disorders, proves conclusively the deleterious effects of its continued use, injuries do not heal so readily in the inebriate as in the temperate, and it is well known that chloroform is not well borne by them, nor can they as well withstand the shock of surgical operations. On the other hand, enormous amounts of alcohol may be ingested by those unaccustomed to it, when meeting with accidents, or suffering from the effects of hemorrhage, bites of insects and serpents, when suddenly depressed, and in convalescence from acute diseases. Infants and old people bear alcoholics well.

Medical Uses and Dosage.—Alcohol is seldom or never used internally, except in dilution. Undiluted, it is a powerful irritant and poison, rapidly causing intoxication, and, if in large quantities, death. It is usually employed in the form of wine, brandy, gin, beer, whiskey, etc., which, in moderate doses, act as diffusible stimulants, and are highly beneficial in prostrating diseases, and in cases where these kinds of stimuli are indicated. Brandy is said to be cordial and stomachic; rum, heating and sudorific; gin and whiskey, diuretic. There are very few cases in which alcoholic stimulants are necessary to be given, and those are seldom of a chronic character, or in which these fluids have to be used longer than a few days. The use of our small doses of concentrated alcoholic preparations, and improved modes of treating diseases, have done much to set aside the dangerous and unscientific practice of indiscriminately prescribing alcoholics. Exceptions to its non-use in chronic disorders, are cases of great debility with feeble digestion, such as the *gastric debility* of old age, and wasting of tissue, in *phthisis*. Here, as long as it favors digestion, acts kindly and prevents tissue waste, it is of marked value. If, however, it should occasion unpleasant symptoms, it will aggravate *phthisis*, a form of which is also known to result from alcoholic excesses. An ounce of brandy or whiskey may be given with milk, egg-nog, broth, or other liquid food; when cod-liver oil agrees with

the stomach, alcoholics may be given with it. While in small doses it is a stomach tonic, it should not be employed in ordinary atony of the stomach, which other agents will overcome, on account of the danger of fixing upon the patient the alcoholic habit. Nor should those subject to neuralgic pains make general use of it; and for general, chronic adynamic states it is of less value than other agents.

Alcohol is mostly employed in acute disorders. Its utility in *delirium tremens* is well established. It will aggravate cases dependent upon the direct and sudden action of excess of alcoholics upon the gray brain-matter, but when it depends upon failure of the stomach to take and appropriate food, no remedy is more efficient; and opium and other stimulants assist its action. As long as the patient is able to take and retain and digest food, delirium will not occur. As soon, however, as gastric rebellion ensues, the stimulant must be given to allay the irritability and sustain the nervous powers. An ounce of whiskey, alone, or in milk, may be given every hour or two until the stomach will act without its aid. Give no more than enough to sustain the nervous system (Locke). In *high fevers* and *inflammations*, in those accustomed to the use of alcoholics, it is dangerous to wholly withdraw the stimulant, and it may be given at intervals in small doses. In acute diseases it is never admissible where there is determination of blood to the brain, or where there is severe, darting headache of a throbbing character, suffusion of the skin and eyes, and noisy or violent delirium. Nor should it be continued in any case where it increases the rapidity of the pulse, elevates temperature, or causes or increases dryness of the tongue. The condition in which it is admissible, is that of prostration, as in *low fevers*, the pulse being soft and feeble. Small quantities should be frequently repeated. Thus, in *typhoid*, and other *low fevers*, where there is a tendency to fainting, with low, muttering delirium, and dry tongue, the patient will die unless stimulation is resorted to, and nothing is better for this purpose than alcohol. Add 1 ounce of brandy to 3 of milk and give frequently, as necessary. If it slows the pulse, rendering it fuller, calms the delirium, tends to moisten the tongue and promote sleep, it is doing good as well as acting as food; if it increases the symptoms, it is doing harm, and should be discontinued.

In certain forms of *vomiting*, as of *sea-sickness* and *pregnancy*, alcoholics are of service. Give a glass of wine before rising from bed in the morning in the latter complaint. *Insomnia* and *somnambulism*, both when due to cerebral anemia, are benefited by alcohol. Refreshing sleep will follow its administration. Hyperemia of the brain contraindicates it. Threatened *inflammation* of the internal organs from exposure or cold, causing suppression of the functions of the skin, is often averted by a hot toddy and putting the patient to bed. In this manner, threatened *pleurisy* and *pneumonia* may be prevented. In the *exanthemata*, when exhaustion threatens, alcohol may be resorted to. In the collapse of *Asiatic cholera*, it is called for, and is of value in some cases of *traumatic tetanus*. Large doses sustain the nervous system while undergoing the effects of *serpent* and *insect bites and stings*. It should also be locally applied. Alcohol may be made to act as an external stimulant or refrigerant, by merely applying it to a part, and preventing its evaporation by placing a compress of linen or muslin over it, to produce the first effect; or, by allowing it to evaporate, to produce the latter. With an equal quantity of water, it forms a good dressing for *bruises*, *orchitis*, *arthritis*, and other *superficial inflammations*. *Cracked nipples*, should be bathed with brandy and dusted with bismuth subnitrate (Locke). Applied to threatened *bed-sores*, it hardens the tissues and prevents excoriations. Dr. Christison recommends "a mixture of equal parts of rectified spirit and white of egg as an application to *excoriations*, from pressure, in fever and other exhausting diseases. It is to be applied frequently with a fine brush or feather, and renewed as it dries, till an albuminous coating is formed over the part."

As a dressing to fresh *wounds*, alcohol, diluted, is of much value; and even in *suppurative injuries*, it corrects fetor and acts as an antiseptic, as well as to stimulate granulation. Owing to its coagulating power over albuminous material, alcohol is a hemostatic in conditions in which the blood slowly oozes, as from *abrasions*. *Aural polypi* and *unhealthy granulations of the tympanum*, the result of long suppurative processes, are well treated with absolute alcohol. This it does

by coagulating albumen and abstracting water, and may cause permanent dryness of the tympanic membrane. Foltz regards it a specific in *tympanic cholesteatoma* (*Dynam. Ther.*). The dose of alcoholics (brandy, whiskey, etc.) should not be such as to exceed $1\frac{1}{2}$ fluid ounces of absolute alcohol, except in serpent poisoning, when more may be given.

Specific Indications and Uses.—Prostration, with soft, feeble pulse, hurried respiration, and irregular heart action; prostration, with dry tongue, low, muttering, or wandering delirium, tremor, subsultus, and insomnia; delirium tremens, when the gastric powers fail. Locally, to cholesteatoma of the tympanic cavity (absolute alcohol).

ALCOHOL AMYLICUM.—AMYLIC ALCOHOL.

FORMULA: $C_5H_{11}OH$. MOLECULAR WEIGHT: 88.

SYNONYMS: *Fusel oil*, *Oil of potato spirit*, *Corn spirit oil*, *Amyl alcohol*, *Pentyl alcohol*, *Grain oil*, *Amyl hydrate*, *Amyl hydroxide*, *Primary amyl alcohol*.

Preparation and History.—"Take of the light liquid, which may be obtained at any large distillery, by continuing the distillation for some time after the pure spirit has all been drawn off, any quantity. Introduce it into a small still or retort connected with a condenser, and apply heat so as to cause distillation; as soon as the oil begins to come over unmixed with water, the receiver should be changed, and the distillation being resumed and carried nearly to dryness, the desired product will be obtained. The liquid drawn over during the first part of the distillation, will consist of an aqueous fluid, surmounted by a stratum of the amylic alcohol. This latter, though impregnated with a minute quantity of water, should be separated and preserved, as being sufficiently pure for use"—(*Dub.*). It is usually prepared from fermented cereals, or potatoes, by distillation.

Amylic alcohol was first noticed by Scheele, in the spirit obtained by distilling fermented potatoes, and was called *Oil of potato spirit*; since his time its general character has been more fully investigated by several chemists. It is now found not only in potato spirit, but among the products of alcoholic fermentation generally, in which it exists in the $\frac{1}{100}$ or $\frac{1}{1000}$ part. When alcohol is distilled from potatoes, toward the termination of the process a whitish fluid passes over, which, when allowed to rest, yields a deposit of amylic alcohol, combined with nearly equal parts of water and alcohol. This is washed several times in water, then placed in contact with chloride of calcium to remove the water, and distilled over again, in order to purify it. Alcohol and water pass over at first, but as the heat becomes elevated to $132.2^\circ C.$ ($270^\circ F.$), a clean receiver is substituted for the one just used, into which the pure amylic alcohol is received as it passes over. It is viewed as a hydrated oxide of amyl.

Description.—Amyl alcohol is a limpid, transparent, very mobile, oily liquid, colorless, or of a light-yellow color, having a very nauseous odor, producing stupefaction, and an acrid, sickening taste. Its vapor, when inhaled, causes cough and spasmodic dyspnea, resembling asthma, often followed by vomiting. It produces an evanescent stain on paper; gives a bluish-white flame when burned with a wick, or heated to $55^\circ C.$ ($131^\circ F.$); boils at about $132^\circ C.$ ($269.5^\circ F.$); has the specific gravity 0.818; and absorbs hydrochloric acid gas largely, heat accompanying the process. It unites in any quantity with alcohol, ether, fixed and volatile oils, and concentrated acetic acid; is hardly dissolved by water, to which it imparts its odor, and the property of becoming beaded when shaken. Iodine, camphor, phosphorus, resins, fatty matters, sulphur, etc., are dissolved by it; and it combines with solutions of potash or soda without alteration. Heated with dry potash, it undergoes decomposition, evolving hydrogen, and forming valerianate of potassium by absorption of oxygen. According to Pasteur, ordinary amylic alcohol consists of a mixture of two metameric bodies, one being inactive on polarized light, the other producing left-handed rotation of a polarized ray; these two alcohols can be separated. Fusel oil may be detected in alcohol by introducing the suspected fluid into a burette, diluting it with its volume of rectified ether, and an equal volume of distilled water;

slightly agitate and allow it to rest. The ether will float upon the surface of the liquid, holding all the fusel oil in solution. Separate the ether by the usual method, allow it to evaporate spontaneously, and the fusel oil remains behind, known by its bad odor. Amyl alcohol of commerce contains from 20 to 30 per cent of common alcohol. By exposure to the atmosphere in the presence of platinum-black, slow oxidation takes place, with the formation of valerianic acid as the result.

Hirsch (*Amer. Jour. Pharm.*, 1862) has proposed to remove alcohol from fusel oil by the following process: Shake fusel oil with an equal volume of saturated salt solution, repeat the operation, finally shaking out with pure water. Then distill the washed fusel oil with 3 to 4 times its weight of distilled water in a retort; the distillate will then consist of an oily layer of almost pure amyl alcohol, and an aqueous layer containing what little alcohol has remained unabstracted in the preceding treatment.

Action and Medical Uses.—Valerianic acid, and several medicinal valerianates, are prepared by the aid of amylic alcohol. It is also used in preparing amyl nitrite, artificial fruit essences, and in the production of certain proximate principles, alkaloids, etc., notably the cinchona alkaloids. Fusel oil is said to produce the peculiar nervous and dyspeptic symptoms of those accustomed to consuming large amounts of alcoholics; the rapid intoxication produced sometimes, is likewise attributed to this body, occurring as an adulterant. Even in small doses, amylic alcohol induces a tensive pain in the head, while in excessive amounts, insensibility and profound narcosis result. The breath exhales a fruit-like odor. Among the poisonous symptoms are giddiness, staggering, headache, diplopia, unconsciousness, reduction in temperature, rigidity and subsequent relaxation of the muscles, marked cyanosis, and death. In cases of poisoning by it, ether and other stimulants may be subcutaneously injected. Amylic alcohol, in very small doses, is a nerve stimulant. It has been used in *phthisis*, with negative results. The *nervous irritability* and weakness of habitual drunkards, is said to be relieved by small doses of fusel oil.

ALCOHOL METHYLICUM.—METHYL ALCOHOL.

FORMULA: CH_3OH . MOLECULAR WEIGHT: 31.93.

SYNONYMS: *Wood alcohol*, *Wood naphtha*, *Pyroxylic spirit* (or *alcohol*), *Pyroligneous spirit* (or *alcohol*), *Spiritus pyroxylicus rectificatus*.

Preparation and History.—This substance was first carefully studied and named by Dumas and Peligot (1834), though previously differentiated from ethyl alcohol by Philip Taylor, in 1812, and noticed still earlier by Boyle, in 1661. As a result of the destructive distillation of wood, several substances are obtained (as noticed under *Acetic Acid*), among them 1 per cent of *crude pyroxylic spirit*. When calcium carbonate is added to the aqueous liquor containing the crude product, the salt calcium acetate is formed, and upon distilling the solution, that portion passing over before a temperature of 100°C . (212°F .) is reached, contains the crude wood alcohol. The next step is its purification, which is accomplished by saturating it with fused chloride of lime, forming thereby, with the crude spirit, a crystalline body, which is then distilled to allow impurities to pass over. To separate the pyroxylic spirit from the calcium compound, water is added, and the mixture again distilled, after which it is freed from the water by being left in contact with dry lime, and rectified.

Description and Tests.—Anhydrous methyl alcohol, when pure, is a limpid liquid, colorless, has a pungent, burning taste, and a peculiar odor, somewhat like that of acetic ether and alcohol. Like alcohol, it burns with a pale-blue, though less luminous, flame. Alcohol, ether, and water dissolve it in all proportions, and its solvent properties are said to be the same as those of alcohol. It may be distinguished from acetone by its power of dissolving calcium chloride. It should be free from a smoky odor. Its boiling point is about 67°C . (152.6°F .), and it has a specific gravity of 0.8021 at 15.5°C . (60°F .). Its vapor occasions conjunctival irritation. *Crude pyroxylic spirit* is used largely in the arts and especially as a solvent for resins in the manufacture of varnishes. The

methyiated spirit of Great Britain is a mixture of alcohol, $\frac{1}{2}$ parts, and pyroxylic spirit, $\frac{1}{2}$ part. It is employed in laboratories in making ether, nitrous ether, and chloroform, and is used in the arts as well, for its solvent properties and on account of being cheaper than ethyl alcohol, the duty on which is heavy, unless to be used in the arts; then the duty is removed by the Government. But in this case the ethyl alcohol must be mixed with wood-spirit, so as to render it unfit for use in beverages.

At present, an important use of wood alcohol is for the production of formaldehyde (see *Formaldehydum*). Wood alcohol should not become colored by exposure to the air and light. It mixes with water in all proportions, without becoming muddy, and when pure has no action on paper stained with vegetable colors. It may be preserved without alteration in a vessel, though imperfectly corked; but when its vapor, mixed with air, is left in contact with spongy platinum, much heat is evolved, and formic acid is formed. It dissolves many salts, many resins, hydroxides of potassium and sodium, most essential oils, and forms crystalline compounds with chloride of calcium, barium oxide, and lime. The admixture of ethyl alcohol is recognized by the fact that concentrated sulphuric acid will, upon warming, liberate ethylene gas. In the absence of ethyl alcohol, the presence of acetone may be shown by its capacity of yielding iodoform upon warming with iodine and sodium carbonate.

Action, Medical Uses, and Dosage.—The fumes of wood spirit occasion conjunctival irritation, nausea, anorexia, headache, and vertigo. It was the preparation recommended by Dr. J. Hastings as a remedy for *phthisis pulmonalis*; he incorrectly termed it *Wood naphtha*. Although it has no influence in effecting cures in this disease, it is frequently of service in relieving the cough and feverish symptoms which manifest themselves. As to its action in vomiting, Christison says, "I can amply confirm all that has been said of it as an antiemetic remedy in cases of *chronic vomiting*; for in cases of this affection, depending on both functional or organic disease, I have frequently seen the vomiting arrested, or greatly mitigated, by pyroxylic spirit." It has also been found of service in *dysentery* and *diarrhœa*, *dyspepsia*, *catarrhal disorders*, and for the expulsion of *intestinal worms*. The dose is from 5 to 20 drops, 3 or 4 times a day, mixed with a fluid drachm or two of compound tincture of cardamom and a fluid ounce of water. It may be substituted for alcohol in lamps for chemical purposes, and answers exceedingly well for making varnishes, as it is more volatile than alcohol. Bodies which contain much oxygen, are more readily dissolved by it than hydrogenous bodies. It has now been practically abandoned as a medicine.

ALETRIS.—ALETRIS.

The rhizome of *Aletris farinosa*, Linné, gathered after the plant has flowered.

Nat. Ord.—Hæmodoracææ.

ILLUSTRATION.—*Strong's American Flora* (exclusive of root), p. 65.

COMMON NAMES: *Blazing star*, *Star grass*, *Starwort*, *False unicorn root*.

Botanical Source.—Aletris is a small herb found in most parts of the United States. The common name is *Star grass*, but the term *False unicorn* is sometimes used. The name *Unicorn root* is more properly applied to *Chamelirium* (*Helonias*). Aletris is also known as *Blazing star*. The leaves are all radical and grass-like, from $\frac{1}{2}$ to $\frac{3}{4}$ inch wide, and from 2 to 4 inches long. They are smooth, entire, acute, and of a firm texture, and have from 6 to 10 parallel and quite prominent veins. The flowering stem is erect, from 2 to 3 feet high, and arises from the center of the cluster of root leaves. It has no stem leaves, but at intervals of about 2 inches, there are very small, linear scales, which may readily escape detection without a close examination. The stems are round and striate near the base, but angular above. The flowers are perfect, and in slender, terminal, simple racemes. They are on short pedicles, with small bracts at the base. The perianth is cylindrical, urn-shaped, white, with a yellowish tinge at the apex; wrinkled, rough and mealy outside, and 6-cleft at the summit. The stamens are 6, small and included. The ovary is ovate, and tapers

Fig. 14.

Aletris farinosa.

to a slender style, which is trifid at the apex. The fruit is a dry, many-seeded, acute pod, opening by 3 valves.

History and Description.—The commercial drug, under this name, as found upon the market, is generally the rhizome of *Chamælorium* (see *Chamælorium*). Strange as it may seem under these circumstances, the two roots have no resemblance, are utterly unlike, and their appearance forbids admixture. We can not recall a single instance where *Aletris farinosa* was adulterated with *Chamælorium*, and yet so universal has the substitution of the last become, that Prof. King, in describing the root of *Aletris* (*Amer. Disp.*, 8th ed., p. 78), has given a description of that of *Chamælorium*, and *Strong's American Flora* figures the top of *Aletris* with the rhizome of *Chamælorium*. In this connection, we invite attention to our exact engraving of the *Aletris* plant and root (Fig. 14), and, as a comparison, invite attention to the engraving of *Chamælorium* (see *Chamælorium*, Fig. 66).

When dry, the root of *Aletris farinosa* is from $\frac{1}{2}$ to 1 inch in length, seldom longer. It is surrounded and completely hidden by an intricate mass of fibers, remains of radical leaves and partly decayed matter. The recent growth of yearly fibres are white, and from 2 to 6, or even 10, inches in length. In texture, they are made up of a hard, durable, brown, woody center, over which are several layers of white, tissue-like epidermis, that peel off by age, and decay. Thus we find the lower portion of the dry rhizome of *Aletris farinosa* covered by a mass consisting of dead, brown, woody fibers of former years, from which the paper-like envelope has separated, together with white, recent rootlets from which the white epidermis is still scaling; while intermixed, are the chaff-like remains of the epidermis, in various stages of decomposition.

The radical leaves spring directly from the upper part of the growing end of the creeping rhizome. They contain numerous hard, round, woody fibers running lengthwise with the leaf, and from year to year, as the succulent portions of the leaves decay, the fibers remain and hold the fragments of mealy leaf-matter; and thus the upper, as well as the lower portion of the primary root is perfectly concealed from view. The dried root proper is about $\frac{1}{2}$ of an inch in diameter just beneath the leaves, and tapers from this point to nearly $\frac{1}{2}$ of an inch; very often the extreme end turns downward, and usually terminates abruptly. The surface is rough, scaly, and thickly covered with root fibers below, and leaf scars and leaf fibers above. Internally, it is soft, spongy, white or slightly straw-colored, the central portion being less firm than the outer. It is odorless, acrid to the taste, *not bitter*. *Chamælorium* (*Helonias*), on the contrary, is very bitter.

Physicians should insure the identity of *Aletris* when purchasing. There is no excuse for confusion, as the two plants (*Aletris* and *Chamælorium*) are entirely different in appearance, the roots do not resemble each other, and are, to the taste, utterly unlike; and while *Chamælorium* has a peculiar and characteristic odor, the *Aletris* is odorless.

Action, Medical Uses and Dosage.—Owing to the confusion which formerly resulted from the substitution of the root of *aletris* for *helonias*, erroneous statements have been made regarding the status of the drug in female complaints. The drug must be restudied to determine its true place in therapy. Enough is known, however, to place it among the simple bitter tonics and stomachics, and as such it is employed to promote the appetite and aid digestion, and in *flatulence*, *colic*, *borborygmi*, etc. This root and its preparations are almost entirely employed in *dyspeptic conditions*; while, in the abnormal conditions of the female reproductive organs, the *chamælorium* is used. The dose of specific *aletris* is from 5 to 20 drops.

ALISMA.—WATER PLANTAIN.

The leaves of *Alisma plantago*, Linné.

Nat. Ord.—Alismaceæ.

COMMON NAMES: *Water plantain*, *Mad-dog weed*.

Botanical Source, Description, and History.—A perennial, caulescent herb, growing in watery places, along streams, in marshes, and on the borders of ponds. Water plantain has long (4 to 6 inches), radical, oblong, or lanceolate leaves, subcordate at the base, cuspidate, or abruptly acuminate, and borne on long petioles. The flowers, which appear in July and August, are small, white, and numerous, and borne in a loose, whorled panicle on a scape, 1 or 2 feet high. The root is fibrous, and serves a Russian tribe as food. The American species is said to be a variety, and is known as *Alisma plantago*, var. *Americanum*, Gray. In odor, the root when fresh is said to resemble orris root, and has a sickening, acrid taste. A pungent, volatile oil, and a resin, are its only constituents. Water plantain inhabits the North American continent, as well as Europe. The root was formerly considered efficacious in hydrophobia, but repeated trials have shown it to be impotent. The leaves are the parts used.

Action, Medical Uses, and Dosage.—An infusion of the dried leaves is an excellent remedy in *urinary diseases*; the leaves, dried and powdered, have been successfully employed in *gravel*, and other urinary affections. The indications are: "Irritation and uneasiness in passing water, frequent desire to micturate, pain in the loins, and involuntary muscular movement" (Scudder, *Spec. Med.*). Dose of the infusion, from 4 to 6 fluid ounces, 3 or 4 times a day; of the leaves, 1 to 2 drachms. The fresh leaves, bruised and applied to the skin, irritate and redden it, and, not infrequently, will cause vesication.

Specific Indications.—(See above).

ALKANNA.—DYER'S BUGLOSS.

The root of *Alkanna tinctoria*, Tausch; (*Anchusa tinctoria*, Linné; *Lithospermum tinctoria*).

Nat. Ord.—Boraginaceæ.

COMMON NAMES: *Alkanet*, *Dyer's bugloss*.

ILLUSTRATION: Artus' *Hand Atlas*, Vol. II., p. 438.

Botanical Source.—This plant is a weak, hairy herb, about a foot high, with alternate, oblong, entire, bicuspid leaves. The flowers are small, and disposed in terminal racemes, usually in pairs, which unroll as the flowers expand. The calyx is 5-lobed, and the corollas funnel-shaped, with a red tube about the length of the calyx-lobes, and a blue, 5-parted limb. The fruit consists of 4 distinct nutlets, which are contracted, and not hollowed, at the base.

History and Chemical Composition.—The Alkanet plant is indigenous to, and cultivated in the southern part of Europe. The roots of the cultivated plants are not so rich in the red coloring matter as are those grown in their native soil. The genus *Alkanna* is closely related to *Anchusa* and *Lithospermum*, and the roots of all three genera yield red coloring matters. Alkanet root contains the red coloring matter—*anchusin* or *alkanet-red*. To obtain it (Wittstein) the root is exhausted with water to remove gum and foreign coloring matters, then dried, ground, and percolated with alcohol. The alcoholic tincture is acidulated with hydrochloric acid, distilled, and evaporated to the consistence of a soft extract; this is exhausted with ether, water added, and, after agitation, the lower liquid separated. The ethereal solution is again washed with water, decanted, and evaporated. *Anchusin*, is dark, red-brown, brittle, neutral, and volatile, subliming in violet-red vapors. It is insoluble in water, soluble in chloroform and alcohol, more soluble in ether and oils. Sulphuric acid dissolves it with an amethyst color; solution of alkalis, with blue. The other constituents of the plant are unimportant.

Description.—Alkanet root, as obtained in this market, is often worm-eaten, and of very inferior quality. It appears as fragments, mixed with entire roots

from 6 to 12 inches in length. They are dark purple externally, lighter within, pliable and spongy. The root is largely employed by manufacturers of pomades, hair oils, ointments, etc., for the purpose of coloring them. For these purposes, a solution of the *alkannet-red* is made by covering the crushed root with castor-oil, macerating, and straining; the deep red coloring matter is thus obtained, in solution, and this solution is added to the oil or pomade until the desired shade is produced.

Uses.—This root is rarely, if ever, employed therapeutically, though stated to possess emollient properties. Its chief use among pharmacists is for coloring certain articles. It is asserted that it is used to color adulterated wines.

Other Coloring Agents.—*ARNOTTA*, *Annotta*, *Annatto*, *Orellana*, *Oreana*. These various names refer to the coloring principle of the pulp of the seeds of *Bixa Orellana*, Linné (*Nat. Ord.*, Bixaceæ), a medium-sized tree of the American tropical regions. The whitish, obovate and angular seeds are inclosed in deep-red pulp. According to Peckholt (*A. J. P.*, 1859), the coloring matter is obtained by soaking the bruised seeds in water (or allowing them to ferment in water), rubbing the pulp from the seeds by hand, passing the liquid mass through a sieve, and finally mashing the seeds and washing again with more water. The coloring matter is allowed to settle, then dried, and formed into cakes or cylindrical pieces. A coloring matter also remains in the water employed. Prime annotta is plastic, generally quite soft, having the red color of blood, becoming, when exposed to air, of a deep reddish-brown. When dry or old, it is brittle and hard. It has an unpleasant, saline, bitterish taste, and a peculiar sweetish odor. It is scarcely soluble in water, in which it softens, however, and to which it imparts a yellow color. Alcohol, fixed oils, ether, and alkalies dissolve it, an orange-red or deep-red solution being formed. Heat does not fuse it, and it is inflammable. There are two grades known in commerce—the *French* (*flag annotta*), the best for coloring purposes, though it possesses the most disagreeable odor, probably having been prepared by the fermentation process; and the *Spanish* (*Brasilian*), which is not unpleasant to the sense of smell. Annotta contains two coloring principles; one, discovered by Preissner, a non-crystalline, bright-red, resinous body, called *bixin* ($C_{15}H_{12}O_4$, Stein; $C_{22}H_{16}O_5$, Etti); *orellin*, the second coloring body, is yellow, and soluble in water. Nitric acid colors bixin yellow, producing an odorous body resembling musk in odor; sulphuric acid colors bixin blue. Besides other compounds, annotta contains a terebinthinous body and a fatty acid. The seeds contain phosphoric acid, silica, and potassa (Ebert). Annotta is subject to adulteration, the agents employed being sand, chalk, gypsum, brickdust, red ochre, turmeric, and starchy bodies. The mineral impurities will refuse to dissolve in boiling alcohol. Annatto is employed to dye fabrics, especially silk, an orange-yellow fugitive color being imparted. In pharmacy, ointments and plasters are sometimes colored with it, while in the arts it is used to produce "butter color," for giving yellowness to butter and cheese. This preparation may be obtained by digesting annotta, 1 part, until wholly disintegrated, in alcohol, heating with olive oil (or some other bland oil) 4 or 5 parts, by weight. Another method is to add to olive oil (1 part), extract of annotta (10 parts). A small quantity of turmeric is added when the preparation is desired as a cheese-color.

BRAZIL WOOD. Several South American and West Indian species of *Cesalpinia* yield this red dye-wood. There are two chief commercial kinds, (1) *Pernambuco* (*Fernambuco*) wood, the most valued, and the Brazil wood proper, from *Cesalpinia Brasiliensis* and *C. crista*; and (2) *Brasileto*, from the West Indian and Jamaican *C. vesicaria*, of less value. Analogous to *Brasileto* are the *sappan*, or *samfen* wood (from *C. Sappan*), and the *Nicaragua*, or *peach* wood (*C. echinata*). Brazil wood was formerly used in medicine, but now has only a limited use in pharmacy, viz., to color tinctures. It is largely used in dyeing, and to some extent in preparing lakes and red ink. Its coloring matter is extracted by water. The wood has a faintly-sweetish taste, and practically no odor. *Brazilin*, or *brasilin* ($C_{16}H_{14}O_3$), the coloring principle, is sulphur-yellow (colorless if absolutely pure) and crystallizable, sparingly dissolved by water, the solution being clear, nearly colorless, and sweet. Acids do not affect the solution, but alkalies redden it. Ether and alcohol produce pale yellow solutions. *Brazilin* quickly becomes red in the sunlight, and more slowly in diffused light, hence it must be kept in the dark. The red color produced by exposure to light and air is due to the production of *brasilin* ($C_{16}H_{14}O_3$).

Onosma echinoides, Lamark. South Europe. A hairy, rough perennial, whose flowers, at first white, finally become yellow. Theroot, which is conical, and has a deep-red bark which is black on the outer surface, is used as a substitute for alkanna in coloring.

Lawsonia alba, Lamark. (*Nat. Ord.*, Lythraceæ). *Henna*, or *Ahenna*, is produced from this plant, which is much esteemed by the inhabitants of India and other Oriental lands. Mohammed is said to have spoken of it as the "best of herbs." Innumerable conditions are said to be curable with it, among them *headache*, *smallpox*, *leprosy*, and "burning feet," a peculiar and obscure affection met with occasionally in India, etc. Dioscorides speaks of it as a plant "whose leaves dye the hair of an orange color." In Africa and Asia, and among the Mahometans especially, the custom is in vogue of dyeing the feet and hands orange-yellow, a practice said to have prevailed among the ancient Jews and Egyptians. The coloring matter, which appears like a brown-resinoid material, is a sort of tannin to which the name *hennotannic acid* was given by Abd-el-Aziz Herraory.

Mucuna aurantiaca, *Orange* orange. Bark of root yields a yellow dye. Alexander King isolated from it *morin* and *moritannic acids*.

ALLIUM (U. S. P.)—GARLIC.

The bulb of the *Allium sativum*, Linné.

Nat. Ord.—Liliaceæ.

COMMON NAME: *Garlic*.

Botanical Source.—The garlic plant has a stem about 2 feet high, leafy below the middle. It terminates in an umbelliferous head of pink, red or whitish flowers, intermixed with bulbs, enveloped in a calyptriform, horned spathe. They appear in July, and are rather longer than their stamens. The leaves are acute, distichous, glaucous, and channelled above. The medicinal part is the very proliferous, clustered bulbs, many of which are invested in the same silvery skin.

Description.—The bulb is compound, subspherical, covered with membranous scales. About 8 wedge-like, compressed bulblets, are arranged circularly around a central stem-base. The smaller bulbs are appressed laterally, and consist of succulent scales, enveloping a central, fleshy mass. Garlic has an acrid, warm taste, and a disagreeable, pungent, alliaceous odor.

History, Action, and Chemical Constituents.—Garlic is a native of Sicily, and is indigenous in Asia Minor and Central Asia, but is cultivated in gardens in various sections of the United States and Europe. The bulbs of this plant are official; when removed from the ground some of the stem is left attached, so that after desiccation, by exposure to the sun, or in a warm room, several stems may be secured together, thus forming small bundles for sale. The root loses about one-half its weight by drying, but scarcely any of its smell or taste. Garlic should be used without being previously dried. Though changing color, garlic may be preserved in a closed jar with a small amount of alcohol for some length of time, without impairment of its virtues. All parts of this plant, but more especially the bulbs, have a strong, offensive, very penetrating and diffusible smell, and an acrimonious, almost caustic taste; both of these properties are owing to an acrid, volatile oil, of a deep, brownish-yellow color (when crude), heavier than water, and possessing, in a strong degree, the odor and taste of the plant; sulphur is one of its constituents, the oil containing 6 per cent of a compound ($C_6H_{10}S_2$) and 60 per cent of a substance ($C_8H_{10}S_2$); the rest are higher sulphur compounds. Allyl sulphide does not occur in the oil (Semmler, 1892). When purified it is without color, not so heavy as water, and consists chiefly of a sulphur compound. Water dissolves a small amount of it, while in ether and alcohol it is readily soluble. In contact with the skin, it occasions violent pain, rubefaction, and frequently vesication. Garlic yields its properties to alcohol, vinegar, acetic acid, and boiling water by infusion.

Action, Medical Uses, and Dosage.—Garlic is stimulant, diuretic, expectorant, and rubefacient; it is used both for medical and culinary purposes. The medicinal effects above stated are owing to the absorption of its volatile oil, the stimulating action of which causes thirst, promotes the activity of the various excretory organs, as the skin, kidneys, and mucous membrane of the air-tubes, communicating its odor to their excretions. It has been beneficially used in coughs, catarrhal affections, pertussis, hoarseness, worms, and calculous diseases, during the absence of inflammation. Externally, it has been employed as a resolvent in indolent tumors, and as a counter-irritant in cerebral and pulmonary affections. When applied along the spinal column and over the chest of infants, in the form of poultice, it is very useful in pneumonia; and placed over the region of the bladder, it has sometimes proved effectual in producing a discharge of urine when retention has arisen from torpor of the bladder. Garlic juice, oil of sweet almonds, and glycerin, of each equal parts, mixed, and dropped in the ear, has cured several cases of deafness, due probably to excessive cerumen, or to chronic debility of the mucous tissues of the organ of hearing. The dose of fresh garlic is 1 or 2 drachms; of the juice, a small teaspoonful. Large doses cause nausea, vomiting, purging and other unpleasant symptoms. The juice is often made into a syrup with sugar, by nurses, for coughs, catarrh, and pulmonary affections of infants. The odor imparted to the breath by garlic and onions, may be very much diminished by chewing roasted coffee grains, or parsley leaves and seeds.

Related Product.—**ALLYL TRIBROMIDE.** A product closely related to oil of garlic may be produced by the interaction of bromine and allyl iodide. It has the composition $C_3H_5Br_3$ (or $CH_2Br.CHBr.CH_2Br$), and the name *allyl tribromide* or *tribromhydrin*. A product identical with rectified oil of garlic is produced by acting upon allyl iodide with sulphide of potassium in alcoholic solution. Allyl tribromide is a colorless, or pale-yellowish fluid, congealing with the appearance of a stearopten at 10° to 15° C. (50° to 59° F.). Allyl tribromide has been administered in 5-drop doses (in capsules) in *infantile convulsions*, *angina pectoris*, *hyderia*, *asthma*, *whooping-cough*, and similar *spasmodic complaints*.

ALLIUM CEPA.—ONION.

The bulb of the *Allium Cepa*, Linné.

Nat. Ord.—Liliaceæ.

COMMON NAME: *Onion*.

Botanical Source.—The common onion is a biennial garden plant, having a scape, which appears the second year, 2 to 4 feet high, being naked, smooth, straight, stout, swollen at the base, and fistulous, bearing at the top a round umbel of greenish-white flowers. The leaves are round and fistulous, of a shining green color, acute, and shorter than the stem. The part employed is the bulb.

Description.—The onion is a tunicated bulb, compressed or round, or oblong in figure, invested with a shining, thin, dry membrane, of a reddish or white color. It is less pungent to the taste than garlic, with some degree of sweetness, and a peculiar, well-known odor. Onion bulbs are of various shapes and sizes, usually globular, the layers being juicy.

History and Chemical Composition.—This biennial plant is supposed to be a native of Hungary, but is now found in all parts of the world. According to Fourcroy and Vauquelin, onion contains an acrid, volatile oil, uncrystallizable sugar, gum, albumen, woody fiber, acetic and phosphoric acids, phosphate and citrate of calcium, and water. The oil is colorless, acrid, and contains sulphur. It was investigated, in 1892, by Semmler, who found it to be mainly composed of a sulphur compound, $C_4H_7S_2$. A peculiar wine may be made by fermenting the juice of the onion.

Action and Medical Uses.—Onion possesses properties allied to those of garlic, but in a milder degree, and the absorption of its oil and influence upon the system is somewhat similar to that of the oil of garlic. Onions do not agree with all persons, especially dyspeptics, in whom they favor the production of flatus, which, however, is a common symptom among all those who eat largely of them; boiling, in a great measure, deprives them of this property. Sugar and onion-juice form a syrup, much used in domestic practice, for *cough* and other affections of the air-tubes among children. A roasted onion employed as a cataplasm to *suppurating tumors*, or to the ear in *otitis*, has proved beneficial. A saturated tincture of onions made with good Holland gin, has been found serviceable in *gravel* and *dropsical affections*. A cataplasm of onions pounded with vinegar, applied for a number of days, and changed 3 times a day, has been found to cure *corns* and *bunions*.

Related Species.—*Allium Porrum*, Linné. The *Common leek*. *Allium Schanoprasum*, Linné. The *Chives*. *Allium Ascalonicum*, Linné. The *Shallot*. The above species possess similar medicinal qualities, though less active. They have the characteristic odor, though milder, and are cultivated in gardens for the same purpose as the onion.

ALNUS.—TAG ALDER.

The recent bark of the *Alnus serrulata*, Aiton. (*Alnus rubra*).

Nat. Ord.—Betulaceæ.

COMMON NAMES: *Tag alder*, *Red alder*, *Black alder*, *Smooth alder*, *Common alder*.

Botanical Source and History.—This shrub grows plentifully throughout the United States from Southern New England to the western border of the Great Lakes and southward. It occurs as clumps or thickets, along the borders of streams, rivers, ponds, and in swamps, attaining a height of from 6 to 15 feet. The stems are straight and the leaves smooth, somewhat coriaceous, obtuse, doubly

serrate, round or blunt at the apex, and are accompanied by elliptical, obtuse stipules. Its flowers appear in March and April, before the leaves have expanded, and are of a reddish-green color. The pistillate flowers are borne in an erect, and the staminate, in a drooping, catkin. The fruit, which is ovate, often persists throughout the winter and gives rise to the name "tag alder." The bark is brownish-gray when fresh, and has an astringent, bitterish taste.

Chemical Composition.—The bark contains tannin, oils, and resin. The first may be precipitated with gelatin. A lesser quantity is found in the leaves. *Alnus* is chemically antagonized by the mineral acids, alkalies, ferric salts, salts of lead and silver, and gelatin.

Action, Medical Uses, and Dosage.—To the taste tag alder is bitter and astringent. It powerfully increases retrograde metamorphosis and exerts a direct tonic action upon mucous surfaces, aiding digestion and assimilation. It is a true catalytic and a positive anti-putrefactive agent. Locally applied, the decoction stains the skin. The drug stimulates the gastric mucous membrane and causes an increased flow of gastric juice. Applied to the mammæ, the leaves are said to decrease the lacteal secretion. It is alterative, emetic, and astringent.

This much neglected, but very important, remedy is a valuable agent in *scrofulosis*, especially in those cases marked by glandular enlargements and suppuration. Prof. Scudder speaks of it as one of the most valuable of our indigenous remedies, and points to its use in "superficial diseases of the skin and mucous membranes, taking the form of *eczema* or *pustular eruption*." Administered internally and applied locally in these conditions, we may expect from *alnus* the best of results. *Impetigo*, *prurigo*, *herpes*, and *scorbutus*, are diseases in which *alnus* will be of great utility. In *scurfy tetter of the scalp*, in children, it is of much value. The happiest results are obtained from its use in successive crops of *boils*. It is a good agent in *passive hemorrhages*, particularly in *hematuria*, for which a decoction of the cones has also been used, and it is favorably mentioned for *purpura hemorrhagica*. In *marasmus* of children, it is a much praised remedy. Combined with *rumex crispus*, and used locally and internally, it is a good drug in *nursing sore mouth* of mothers. *Alnus* is an important drug in *indigestion* and *dyspepsia*, when resulting from deficient secretion of gastric juice and debility of the muscular coat of the stomach. It may be associated with specific *nux vomica*. In *diarrhæa*, caused by or attended with deficiency of the gastric secretion, it serves an excellent purpose. It has been used with good results as an injection for *leucorrhæa*, and the leaves may "scatter" *indurations of the mammary glands* during the nursing period. Dr. A. D. Ayer reports many cases of *periodical hyperæsthetic rhinitis (hay fever)* cured by *alnus*. He recommends a distillate prepared after the manner of distillate of *hamamelis*. The distillate is first used with an equal bulk of water and snuffed up the nostrils 5 or 6 times daily. It may be increased to full strength in a day or two. If desirous, it may be applied by atomization. At night the nose is smeared with the distillate combined with *petrolatum*. At the same time give internally: R Distillate of *alnus*, gtt. xv to xxx, in a little water, 1 hour before or after meals. Dr. Ayer also recommends this preparation in the acute stage of *gonorrhæa*, and as an antidote to *rhus poisoning*. The remedy is most effectual in infusion (fresh *alnus* bark, ʒj, aqua Oj); dose, a wine-glassful. Specific *alnus*, 1 to 20 drops.

Specific Indications and Uses.—The specific use of this remedy is to improve nutrition and increase waste. It is of particular value in *scrofula*, with feeble vitality, and *chronic skin diseases* exhibiting scaly or pustular eruptions.

Related Species.—*Alnus glutinosa*, Gærtner. (*Betula Alnus*, Linné). Europe. A tree about 30 feet high, the bark of which contains tannin, and is employed for the same purposes as the *Alnus serrulata*. Its bark is probably gathered indiscriminately with that of the latter. The wood resists water, and has been much used for posts and piles, for wet situations, the wood thus becoming very hard and durable. It was formerly employed in making water-pipes, pump-trees and reservoir conduits; in sculpture, turnery and cabinet-making; for making wooden household utensils, wooden shoes and soles, etc. Europeans have used the bark for tanning and dyeing, and a charcoal from its timber in preparing gunpowder (Hogg, *Nat. Hist. of Veg. King*).

Alnus viridis, De Candolle. *Mountain alder*. North America. This species is a shrub 3 or 4 feet high, the bark of which is employed in *dropical complaints* by a British-American tribe of Indians living in the vicinity of Hudson's Bay.

ALOE.-ALOES.

The inspissated juice obtained from the leaves of several species of Aloe.

Nat. Ord.—Liliaceæ.

Official Kinds.—I. *ALOE BARBADENSIS* (U. S. P.), *Barbadoes aloes* (*Curaçao aloes*), *Hepatic aloes*. Derived from the *Aloe vera* (Linné), Webb; (*Aloe vulgaris*, Lamarck; *Aloe perfoliata*, var. *vera*, Linné; *Aloe Barbadensis*, Miller).

II. *ALOE SOCOTRINA* (U. S. P.), *Socotrine aloes*, *Zanzibar aloes*. Derived from *Aloe Perryi*, Baker.

Non-Official Kinds.—*ALOE CAPENSIS* (U. S. P., 1870), *Cape aloes*, *Aloe lucida*. Derived chiefly from *Aloe spicata*, Thunberg, *Aloe ferox*, Lamarck, and *Aloe Lingua*, Linné (*Gasteria Lingua*, Willdenow). Various other species probably contribute to this variety. A kind known as *Jefferabad aloes* enters the Bombay markets, and is thought to be derived from *Aloe abyssinica*, Lamarck.

Botanical Source and History.—*Aloe vera* (Linné), Webb, grows in the East Indies and Barbary; is now cultivated in the West Indies, as well as in some of the southern sections of Europe. The stem is woody, simple, cylindrical, and short; the leaves fleshy, amplexicaul, first spreading, then ascending, lanceolate, glaucous-green, flat above, convex below, armed with hard, distant, reddish spines perpendicular to the margin, and a little mottled with darker color; the parenchyma is slightly colored brown, and very distinct from the tough, leathery cuticle. The scape is axillary, glaucous, reddish, and branched; the spike is cylindrical-ovate. The flowers are at first erect, then spreading, afterward pendulous, yellow, and not longer than the stamens (L). This plant yields the Barbadoes aloes of commerce.

Several species, formerly regarded as distinct, are now regarded as varieties of this species; among them are *Aloe littoralis*, König; *Aloe indica*, Royle, and others.

Aloe Perryi, Baker, the now recognized source of Socotrine aloes, resembles in habit the *Aloe vera* (Linné), Webb, but its leaves are shorter and the tube of the flowers is of a much greater length than the segments. The flowers are also borne on long pedicles and arranged in racemes much looser than those of the Barbadoes plant. The true aloes plant, and that from which the drug was formerly believed to have come, is the *Aloe socotrina*, which inhabits the Island of Socotra. The stem is woody, straight, 1½ feet high, or more, and naked below, where it is strongly marked with the scars of leaves. Leaves amplexicaul, ascending, ensiform, green, curved inward at the point, convex below, rather concave above, marked with numerous small white marginal serratures; parenchyma abounding in a bright brownish-yellow juice. The raceme is cylindrical and unbranched; flowers scarlet at the base, pale in the middle, green at the point. Stamens unequal, three of them longer than the flowers.

Aloe spicata, Thunberg, or *Spiked aloes*, inhabits the southern parts of Africa, where it grows in sandy soil. The stem is woody, round, and about 4 feet high, and from 3 to 5 inches in diameter; the leaves are thick, fleshy, subverticillate, broad at the base, gradually narrowing to the point, full 2 feet long, channeled, distantly toothed, and dotted with a few white spots; their parenchyma is almost colorless. The spike is a foot long, and very compact; the flowers are scarlet, horizontal, campanulate, and filled with a purplish honey. The three petals are broader, ovate, obtuse, and white, with a triple green line; the sepals are narrower, and less concave. The stamens are much longer than the perianth (L). This plant (together with others above mentioned) furnishes the Cape aloes of commerce.

There are several species which furnish medicinal aloes, but the three above named are supposed to yield the principal portion, although but two are now recognized by the U. S. Pharmacopœia. The mucilaginous juice expressed from the parenchymatous tissue of the leaves has no remedial influences; but only that which is procured by incising the air-ducts of the leaves transversely, so that the juice may flow from them or, as stated by M. E. Robiquet, from the intercellular structure between them. M. Marais states that three distinct kinds of Barbadoes aloes have been found in commerce, two of which are probably obtained by simple exudations of the juice from the incised leaves, while the third is the result

obtained by boiling the plant in water and evaporating. These three kinds may be distinguished from the other species of aloes by a common property they have of giving a perfect emulsion when triturated with a little cold water.

Cultivation and Preparation.—Of the method of obtaining Socotrine aloes little is known. In regard to Barbadoes aloes, the authors of the *Pharmacographia* state: "In Barbadoes, where *Aloe vulgaris* [*A. vera* (Linné), Webb] is systematically cultivated for the production of the drug, the plants are set 6 inches apart, in rows which are 1 to 1½ feet asunder, the ground having been carefully prepared and manured. They are kept free from grass and weeds, but yams or pulse are frequently grown between them. The plants are always dwarf, never in the least degree arborescent. Almost all of those above a year old bear flowers, which, being bright yellow, have a beautiful effect. The leaves are 1 to 2 feet long; they are cut annually, but this does not destroy the plant, which, under good cultivation, lasts for several years. The cutting takes place in March and April, and is performed in the heat of the day. The leaves are cut off close to the plant, and placed *very quickly*, the cut end downwards, in a V-shaped, wooden trough, about 4 feet long and 12 to 18 inches deep. This is set on a sharp incline so that the juice, which trickles from the leaves very rapidly, flows down its sides, and finally escapes by a hole at its lower end into a vessel placed beneath. No pressure of any sort is applied to the leaves. It takes about a quarter of an hour to cut leaves enough to fill a trough. The troughs are so distributed as to be easily accessible to the cutters. Their number is generally 5; and by the time the fifth is filled, the cutters return to the first and throw out the leaves, which they regard as exhausted. The leaves are neither infused nor boiled, nor is any use afterwards made of them except for manure. When the vessels receiving the juice become filled, the latter is removed to a cask or reserved for evaporation. This may be done at once, or it may be delayed for weeks or even months, the juice, it is said, not fermenting or spoiling. The evaporation is generally conducted in a copper vessel; at the bottom of this is a large ladle, into which the impurities sink, and are from time to time removed as the boiling goes on. As soon as the inspissation has reached the proper point, which is determined solely by the experienced eye of the workman, the thickened juice is poured into large gourds or into boxes, and allowed to harden"—(*Pharmacographia*).

In Cape Colony, according to Peter MacOwan, a goat-skin is spread in a shallow depression scratched in the earth, and the aloe leaves are radially arranged in such a manner that the juice falls into the center of the skin. When filled, the juice is poured into an iron pot and boiled, great carelessness being manifested by the operator throughout the whole process (see *Pharmacographia*).

Description and Tests.—*ALOE BARBADENSIS* (U. S. P.), *Barbadoes aloes*. This variety comes "in hard masses, orange-brown, opaque, translucent on the edges; fracture waxy or resinous, somewhat conchoidal; odor saffron-like; taste strongly bitter. Mixed with alcohol and examined under the microscope, it exhibits numerous crystals. Mixed with nitric acid, it acquires a red color. *Barbadoes aloes* is not colored, or acquires only a light bluish-green tint on being mixed with sulphuric acid and blowing the vapor of nitric acid over the mixture (difference from *Natal aloes*)"—(U. S. P.). *Barbadoes aloes* is not so bright and clear as the Socotrine variety, is of darker color, more compact texture, drier, though not so brittle, with a stronger and more disagreeable taste, being intensely bitter and nauseous, with little or nothing of the aromatic flavor of the Socotrine; it is extremely apt to induce hemorrhoids, and is principally used among veterinary physicians.

ALOE SOCOTRINA (U. S. P.), *Socotrine aloes*. "In hard masses, occasionally soft in the interior, opaque, yellowish-brown, orange-brown or dark ruby-red, not greenish, translucent on the edges; fracture resinous, somewhat conchoidal. When breathed upon, it emits a fragrant, saffron-like odor. Taste peculiar, strongly bitter. Almost entirely soluble in alcohol and in 4 parts of boiling water. The aqueous solution becomes turbid on cooling and yields a deposit. Mixed with alcohol and examined under the microscope, *Socotrine aloes* exhibits numerous crystals. The powder, on being thoroughly dried on a water-bath and then heated to 100° C. (212° F.), should not cake. Mixed with nitric acid, it acquires a reddish-brown color. *Socotrine aloes* is not colored blue on being mixed with sulphuric acid and blowing the vapor of nitric acid over the mixture (difference from

Natal aloes)"—(*U. S. P.*). It is hard and friable in the winter, somewhat plastic in summer, and growing soft between the fingers; easily pulverizable; and, when reduced to powder, of a bright, golden color. Aloes of superior value, whether from the Island of Socotra or not, are often commercially designated as *Socotrine aloes*—(*Ed., Duncan*).

ALOE CAPENSIS, Cape aloes (*Shining aloes*). *Cape aloes* has a glossy or resinous fracture, a deep-brown or olive color, with a greenish tint, a shining, smooth surface; and thin scales of it are nearly transparent, having a ruby color. Its odor is more powerful and unpleasant than the *Barbadoes aloes*; its taste peculiar and bitter; and its powder is bright yellow, somewhat like gamboge, but having a greenish tint. The finer East Indian varieties are sometimes confounded with the *Socotrine*.

OTHER ALOES.—*Hepatic aloes* is the name applied to a variety of *Socotrine aloes* at one time commercial in Europe. In this country *Barbadoes aloes* has been called by this name. Any of the opaque and liver-colored aloes have also been known under this term. *Jefferabad aloes* (already referred to) is inferior in taste and odor to the *Socotrine* and has a lustrous, pitch-black color. *Natal aloes*, from Natal, is of a pale brown-yellow or a brown-gray color, quite different from the other varieties. It is carefully prepared, but the plant yielding it is still undetermined. *Moka aloes*, is a disagreeably odorous, nearly black, opaque variety, prepared in Arabia. *Caballine aloes* (*Horse aloes*) was the term by which impure and fetid grades of various sources were formerly known in European commerce.

Aloe Purificata (*U. S. P.*), **PURIFIED ALOES.**—The following is the Pharmacopœial method for purifying aloes and a description of the product: Take "*Socotrine aloes*, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, two hundred cubiccentimeters (200 Cc.) [6 fl. 3, 366 M]. Heat the aloes by means of a water-bath until it is completely melted. Then add the alcohol, and having stirred the mixture thoroughly, strain it through a No. 60 sieve, which has just been dipped into boiling water. Evaporate the strained mixture by means of a water-bath, constantly stirring, until a thread of the mass becomes brittle on cooling. Lastly, break the product when cold into pieces of a convenient size, and keep it in well-stoppered bottles. The product is in irregular, brittle pieces of a dull-brown or reddish-brown color, and having the peculiar, aromatic odor of *Socotrine aloes*. It is almost entirely soluble in alcohol"—(*U. S. P.*). Aloe should never be boiled for any length of time, as its medicinal virtues are thereby diminished. It is dissolved by alcohol, whether diluted or not. A clear solution made with cold water reddens litmus, gives a deep, olive-brown color with ferric chloride, is deepened in color by alkalies, is unchanged with gelatin, and forms a copious yellow precipitate with acetate of lead. Heat occasions fusing, frothing, charring, and ignition, burning with a crackling noise, and a dense smoke which has the peculiar aloetic smell.

Chemical Composition.—The disagreeable odor and taste of aloes is due to a pale yellow, mobile, volatile oil, but minute traces of it existing in the plant. Aloes contains a resin, *Resin of aloes*, being that portion which separates upon cooling the hot aqueous solution of the drug. The chief body of interest, however, is that announced by T. & H. Smith, of Edinburg, and called *aloin*. As it was first found in *Barbadoes aloes*, it is now known as *barbaloin*, since a similar but distinctly different substance was later found in *Socotrine aloes*, called *socaloin*, and in the *Natal* variety, *nataloin*, all three being closely connected chemically, but having each distinctive differences. The *aloëtin* (*aloësin*, *resino-amara* [of Braconnot], or *aloe bitter*), the *bitter extractive* of aloes of Robiquet and other early investigators, was probably *aloin* in an impure, or at least modified, condition. The official *aloin* is composed of *barbaloin* or *socaloin* (see *Aloinum*).

Barbaloin ($C_{17}H_{20}O_7$, Sommaruga and Egger, 1874), forms small yellow crystals, soluble in water, alcohol and ether (see *Aloinum*). Brilliant yellow needles of *bromaloin* may be produced with it by treating its cold, aqueous solution with bromine water, and recrystallizing from alcohol; *chloraloin* may likewise be produced from it. A rapidly-fading crimson color is struck when treated to a drop of nitric acid. Heated with the same acid, it yields aloetic, chrysammic, picric and oxalic acids (Tilden).

Socaloin ($C_{12}H_{10}O_7$, Sommaruga and Egger), was observed by Pareira (1852) in the liquid Socotrine aloes, brought into England and isolated, in 1856, by T. B. Groves, who regarded it as identical with the preceding. Histed (1871) proved it to be distinct. It forms in small, tufted, yellow needle-crystals, soluble in absolute alcohol, water, ether, acetic ether, and methyl alcohol (see *Aloinum*). Heated with nitric acid an orange-red coloration ensues, and acids corresponding with those obtained from barbaloin are obtained. This form is also known as *zanaloin*. Tilden, in 1886, obtained from both kinds of aloin yellow crystals of aloroxanthin (methyl-tetraoxyanthraquinone) by oxidation with potassium chromate and sulphuric acid.

Nataloin ($C_{12}H_{10}O_7$, Sommaruga and Egger) was first isolated by Prof. Flückiger, in 1871, from Natal aloes. It forms thin, light-yellow scales, soluble, according to Flückiger, at $15.5^{\circ} C.$ ($60^{\circ} F.$), in methylic alcohol (1 in 35), acetic ether (1 in 50), ether (1 in 1236), and in absolute alcohol (1 in 230). Water, hot or cold, very sparingly dissolves it. It is soluble in alcohol (60 parts). Picric and oxalic acids, but not chrysammic acid, are formed from it by treatment with nitric acid. This variety does not yield a bromine compound.

If the formulæ above given for the three varieties of aloin by E. von Sommaruga and Egger, of Vienna (1874), be correct, these bodies would seem to constitute an homologous series.

The following beautiful tests for the three aloins were pointed out by Histed: "A drop of nitric acid on a porcelain slab gives, with a few particles of barbaloin or nataloin, a vivid crimson, but produces little effect with socaloin. To distinguish barbaloin from nataloin, test each by adding a minute quantity to a drop or two of oil of vitriol, then allowing the vapour from a rod touched with nitric acid to pass over the surface. Barbaloin (and socaloin) will undergo no change, but nataloin will assume a fine blue"—(*Pharmacographia*).

The afore-mentioned *aloetic acid* has the composition $C_7H_5(NO_2)_2O$, and is orange-red, while *chrysammic acid* ($C_{14}H_4[NO_2]_4[OH]_2O$), occurs in laminæ of a vivid golden-yellow color. It has an explosive property when heated. Needles of an indigo color of the sublimable body *hydrochrysamide*, are produced from the last-named acid by means of deoxidizers. The resin of aloes was found by Tilden and Rammell, in 1872, to be separable into two resins—one soluble by prolonged boiling; the other insoluble. While both are nearly similar to barbaloin in composition, the first lacks the elements of water, being regarded as the anhydrid of barbaloin. The insoluble resin is very similar in structure.

Czumpelik (1861), by prolonged boiling of Socotrine aloes with an alkali, and Hlasiwetz (1865) with sulphuric acid, obtained *para-cumaric acid* ($C_6H_4[OH]_2 \cdot CH:CH \cdot COOH$). This, when fused with potassium hydroxide, yields *para-oxybenzoic acid*. *Alorcinic acid* was also obtained with these bodies by Weselsky (1872). By distillation of aloes with quick-lime, Robiquet (1846) obtained a yellowish oil, *aloisol*, an odorous body since shown by Rembold to be a mixture of xyleneol (dimethylated phenol), acetone, and hydrocarbons. Aloes, distilled with zinc-dust, yielded Graebe and Liebermann (1868) *anthracene* ($C_{14}H_{10}$), and Liebelt, in E. Schmidt's laboratory, *methylanthracene*.

Action, Medical Uses, and Dosage.—Tonic, purgative, emmenagogue, and anthelmintic. In doses of from $\frac{1}{2}$ grain to 1 grain, 2 or 3 times a day, aloes exerts a decided tonic influence, but is seldom resorted to for this purpose. As a laxative and purgative, its applications are unbounded; it acts more especially on the muscular coat of the large intestines, rather increasing their peristaltic motion than effecting copious, thin or watery discharges; and from its tendency to produce heat and irritation about the anus, it is extremely improper (except in minute doses in debilitated individuals) for persons disposed to or troubled with piles. When applied endermically to an ulcer or blistered surface, it purges as effectually and promptly as when taken into the stomach; 10 grains used thus will purge in from 6 to 10 hours. Administered to nursing mothers it will purge the sucking child. It is commonly supposed to have no action on the jejunum or ileum; and some imagine it to influence the duodenum, especially the mouths of the biliary ducts, causing an increased flow of bile and stimulating the intestinal canal, when that secretion is suspended, as in jaundice. It acts upon the uterus, promoting the menstrual flow, which is partly owing to the

stimulation of the organ, and the determination of blood toward it, occasioned by the medicine. It is said that 1 to 3 grains of extract of hyoscyamus, or hops, or 2 grains of ipecacuanha, mixed with the aloetic dose, will prevent its irritating effect on the lower intestines. An increase of the quantity of aloes beyond the medium dose is not attended by a corresponding increase of effect. Aloes has been efficacious in *constipation*, *dyspepsia*, and *ascarides*; in this last instance being used in form of an injection, 10 grains to 3 ounces of water, for children. In *chlorosis* and *amenorrhœa*, it has often proved serviceable, and is used for this purpose in various combinations. In cases of delicate females, with loss of appetite, torpor of the bowels, and suffering, with *suppression of the menses*, the following has been recommended for the purpose of exciting proper ovarian or uterine action: Take of the best aloes, pulverized, asafœtida, pulverized, each, $\frac{1}{2}$ drachm; cantharides, pulverized, 20 grains; mix and rub well together with a little soap, and divide into 20 pills. Of these give from 1 to 3, 3 times a day. If the patient be very feeble, some of the salts of iron may also be added. Injections of aloes, composed of from 10 to 30 grains dissolved in 2 or 3 fluid ounces of water, and thrown up the rectum daily, and continued for a week previous to the menstrual period, have sometimes proved effectual. For *habitual constipation*, aloes should never be given in cathartic doses. Debility and marked intestinal torpor point to its selection. R Aloes, gr. j; powdered ipecac, gr. ss; extract nux vom., gr. $\frac{1}{2}$. Mix. Make 1 pill. Sig.: Give 1 such pill from 1 to 3 times a day, according to the condition. If the liver is active, less of aloes will be required than if it be torpid. A pill of aloin, belladonna, ipecac and strychnine, is much used in *chronic constipation*. There are some cases of *piles*, with marked relaxation of the rectal tissues, that are benefited by minute doses of aloes or aloin, and both are effectual remedies in *rectal prolapse*, due to debility. In both cases there is an associated condition of feeble innervation, in which case the minute dose tends to increase the nutrition of the nervous system.

Aloes should never be given in inflammatory affections, in irritable, plethoric habits, in gastritis, enteritis, and, as a rule, where piles are present; nor to females liable to sudden uterine evacuations, nor during pregnancy. In hemorrhoids it may be given when modified by combination, or in the minute doses above referred to. Soap, or an alkaline carbonate, lessens its irritant action. The union of other purgatives with aloes often modifies its tendency to irritate the rectum. One grain of aloes with 2 or 3 grains of sulphate of iron will also modify this action, and will produce as much effect as 2 or 3 grains of aloes. As a laxative, aloes will be found useful in *habitual constipation*, from intestinal torpor, *jaundice*, *scrofula*, *hypochondriasis*; and as a cathartic, where there is a tendency to *cerebral congestion*. Dose of aloes is from $\frac{1}{2}$ to 10, or even 20, grains; and the most convenient form of administration is that of pill. It enters as a constituent into a great number of useful compound remedies.

Specific Indications and Uses.—"Atony of large intestine and rectum, mucoid discharges, prolapsus ani, pruritis ani, ascaris vermicularis" (Scudder, *Dis. of Children*, 1882). Difficulty in evacuating the lower bowel.

ALCINUM (U. S. P.)—ALCIN.

"A neutral principle obtained from several varieties of Aloes, chiefly Barbadoes Aloes (yielding Barbaloin); and Socotra or Zanzibar Aloes (yielding Socaloin)—differing more or less in chemical composition and physical properties, according to the source from which it is derived"—(U. S. P.).

Preparation.—There are several methods of preparing this substance. One part of aloes may be dissolved in 10 parts of boiling water, the fluid portion decanted, and slightly acidulated with hydrochloric acid (Groves). Or the aloes may be previously made acid with sulphuric, hydrochloric, or sulphurous acid, and allowed to stand a half-day (Tilden). Then rapidly evaporate to 2 parts and set aside, that crystals may form. To purify, recrystallize from alcohol very much diluted. These methods answer well for barbaloin. Socaloin is best obtained by digesting for a day 1 part of aloes in 3 parts of alcohol, and then boiling the mixture on a water-bath for 2 hours. Cool, filter, and allow crystals

to form, which are to be washed with a small portion of alcohol and then dried (Plenge, *Amer. Jour. Pharm.*, 1884).

Description and Tests.—Barbaloin, when pure, crystallizes in stellated groups of small, prismatic needles, whose purity is shown by the color, which should not deepen by exposure to the air in desiccation. Its solutions in the alkalies and their carbonates are orange-yellow, and the liquid absorbs oxygen upon contact with the atmosphere, which rapidly deepens its color. Boiled with alkalies or acids, it is speedily transformed into a brown resin. Corrosive sublimate, nitrate of silver, or neutral acetate of lead, do not cause its precipitation; concentrated subacetate of lead produces a precipitate of an intense yellow, soluble in excess of water, and becoming deeper colored on exposure. Cold fuming nitric acid dissolves it, without disengaging gas, forming a reddish-brown liquid; to which, if sulphuric acid be added in great excess, a yellow, pulverulent body is thrown down, which explodes when heated. By dry distillation, aloin furnishes a slightly aromatic, volatile oil, and a quantity of resinous substance. It forms crystallized compounds with bromine, but not with chlorine, although it combines equally well with the latter. The official aloin may be either barbaloin or socaloin, or both. (For the chemistry of these substances, see under *Aloe*).

"Minute, acicular crystals, or a microcrystalline powder, varying in color from yellow to yellowish-brown, odorless, or possessing a slight odor of aloes, of a characteristic, bitter taste, and permanent in the air. Barbaloin is soluble at 15° C. (59° F.), in about 60 parts of water, 20 parts of alcohol, or 470 parts of ether. Socaloin is soluble in about 60 parts of water, 30 parts of absolute alcohol, 380 parts of ether, or 9 parts of acetic ether. When heated, aloin melts, and, on ignition, it is consumed without leaving a residue. An alcoholic solution of aloin is neutral to litmus paper. An aqueous solution of aloin is colored greenish-black by ferric chloride T.S., and slowly precipitated by basic lead acetate T.S. On adding a minute portion of barbaloin to a drop of cold nitric acid of specific gravity 1.200, on a white porcelain surface, a crimson color will be developed. Socaloin will produce scarcely any color when thus treated. In alkaline solutions, aloin is rapidly decomposed; in neutral, or acid solutions, only slowly"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The action of aloin is similar to that of aloes, except that this agent will produce the effects of aloes in about one-third as large a dose, and is said to be freer from irritant effects. Dose: $\frac{1}{16}$ to $\frac{1}{2}$ grain.

ALSTONIA CONSTRICTA.—ALSTONIA BARK.

The bark of *Alstonia constricta*, F. Mueller.

Nat. Ord.—Apocynaceæ.

COMMON NAMES: *Native quinine of Australia, Australian fever bark, Fever bark, Bitter bark, Alstonia bark.*

Botanical Source.—The genus *Alstonia* comprises about twelve species, seven of them being given in Benthams' *Flora of Australia*. They are milk bear-

Fig. 15.

ing shrubs or trees, with large, entire, generally whorled leaves, and terminal cymes of white flowers. *Alstonia constricta*, F. Mueller, is a lactescent, smooth tree, found growing only in Australia, and has large, opposite, entire oblong leaves about 4 inches long, borne on slender leaf-stalks. The flowers are small, white, numerous, and disposed in corymbose cymes. The calyx is deeply 5-parted and has ovate acute lobes. The corolla has a bell-shaped tube, about twice the length of the calyx, and 5 equal spreading lobes. The stamens are 5, distinct and included. The pistil consists of 2 carpels, with a single style. The fruit consists of a pair of slender, smooth pods, from 3 to 8 inches in length, and containing numerous, flat, pubescent seeds, the upper margins of which are fringed with long hairs.

Bark of *Alstonia constricta*.

Description, Chemical Composition, and History.—The bark is used in Australia as an antiperiodic. As found in commerce, it is in pieces varying in length from 6 inches to 2 feet, from $\frac{1}{2}$ inch to 3 inches in thickness, and from 2 to 4 inches in width. That from the young trees or branches is often curled, like cinnamon bark, until the edges meet, or even overlap. The accurate description given by Mr. Chas. Mohr in the *Amer. Jour. Pharm.*, August, 1879, is as follows: "The bark occurs in semicircular pieces of various length, about 4 inches wide and from $1\frac{1}{2}$ to 2 inches and over in thickness, according to the more or less exuberant development of the corky layers. The rough outer bark is furrowed by more or less broad and deep longitudinal fissures, presenting in the cross section a margin correspondingly deeply indented by irregular, more or less wide and deep sinuosities. The exposed surface of the bark is of a dingy gray-brown, and of an ochre color where fresh layers of cork are exposed. This outer bark, forming far the largest part, shows in the cross section a mottled yellow and brownish color, resulting from somewhat irregular, concentric layers of a clear ochry-yellow, alternating with bands of a deeper tint. It is of spongy texture and friable. The middle and inner layers, about $\frac{1}{2}$ of an inch in thickness, are compact and homogeneous in the cross sections, of a yellow color, and under the lens appearing punctate from the darker faces of the bast-bundles; of a fibrous structure, hard and tough, and on the inner side serrated by longitudinal ridges, caused by the impressions of the bast-bundles upon the cambial layer. The powder of the bark is of a dingy yellow, and possesses a faint, not unpleasant odor, and a lasting, purely bitter taste. The active principles are contained chiefly in the middle and inner bark."

This bark is of a comparatively recent introduction, having been shown for the first time in this country at the Centennial Exposition, in the Australian department, where it was asserted by its exhibitors to be a remedy for malarial fevers. A Cincinnati gentleman, having had his attention strongly attracted toward these assertions, procured a specimen of the bark and, after investigation, having found it to possess therapeutical virtues, he ordered a supply from Australia, intending to introduce it as a proprietary medicine. Prof. J. M. Scudder, of Cincinnati, persuaded him, however, to give up his intention, and allow it to come before the medical profession under its true name, *Alstonia constricta*, the positive identification of which Mr. Charles Mohr effected through specimens sent by him to Sir Joseph Hooker.

The chemical constituents have been investigated repeatedly. *Alstonine* (chlorogenine of Hesse), is the name given in Wittstein's *Organic Constituents of Plants*, for an orange-yellow, amorphous alkaloid, isolated by Mueller and Rummel. Mohr (1879) found a substance agreeing with that of M. and R. in all respects, and announced the probable presence of another proximate constituent; but want of material prevented a thorough examination. Oberlin and Schlagdenhauffen (*Pharm. Jour. and Trans.*, June, 1879, from "*Jour. de Pharm. et de Chimie*"). report an analysis of the bark, and the isolation of two alkaloids: One, *alstonine*, in crystalline tufts, bitter, colorless, soluble in alcohol, chloroform, and benzin; insoluble in cold, but somewhat in boiling water; soluble in nitric, hydrochloric and sulphuric acids, without color, but which neutralizes acids, changes red litmus paper to blue, and the acid solutions of which produce fluorescent (blue) liquids. The other, "*alstonicine*," is amorphous, and is obtained from the mother liquor after the production of *alstonine*. It somewhat resembles *alstonine*, but is not as soluble in boiling water, turns a red-crimson color with nitric, and greenish-brown with sulphuric and hydrochloric acids, and the acid solutions are not fluorescent. In 1880, Hesse established with certainty the presence of the following three alkaloids: *Alstonine* ($C_{27}H_{39}N_3O_4$), identical with his chlorogenine of 1865 and the *alstonine* of Palm (1863); orange-yellow, not easily soluble in water, easily soluble in alcohol, chloroform, ether and dilute acids, the solutions having blue fluorescence. *Porphyryne* ($C_{24}H_{27}N_3O_4$), is white and non-crystalline; dissolves in concentrated sulphuric acid with purple color, the acid solutions being fluorescent, with blue color. *Alstonidine*, less soluble in petroleum benzin than porphyryne. Hesse indicated the existence of other alkaloids besides those mentioned. All reports agree, however, that these proximate principles exist in very small amount. Doubtless, either the bark in substance, or the

tincture, or the fluid extract, will be the medicinal preparations employed; the most effectual being prepared from the *inner bark*.

Von Mueller appears to have been the first person who made known the febrifuge properties of this bark, in 1870, in an address before the Industrial Museum of Melbourne; in 1874, in a published statement relative to certain select plants, he again remarks that the bark of *A. constricta* is aromatic, bitter, and regarded as valuable in ague; also as a general tonic. It was subsequently referred to as an antiperiodic, in 1876, by Dr. A. Cathcart, of South Wales. Its introduction to the materia medica of this country justly belongs to Prof. J. M. Scudder, M. D., of Cincinnati. It is said that English brewers substitute it for hops in the making of pale export beer, for, unlike the hops, it will not produce headache (Christy). A decoction of fever bark is sold in some of the English colonies as "bitters."

Action, Medical Uses, and Dosage.—The inner bark of *Alstonia constricta* is said to possess marked antiperiodic properties, while the outer bark is stated to have been efficacious in curing certain forms of *rheumatism*. Further trials are needed, however, before it can be ranked as a substitute for quinine, or other of the cinchona alkaloids, yet it has proved as efficient in *intermittents*. "Hesse attributes to alstonidine properties analogous at once to those of quinine and to *nux vomica*. The experiments of Bancroft and of Bixby prove that this drug is valuable as a tonic febrifuge, and more valuable as a febrifuge than as a tonic, while the *Alstonia scholaris* is more generally employed against dysentery" (Beringer, *Amer. Jour. Pharm.*, 1895, p. 167).

Prof. King has used the bark in several cases with prompt and decided success; four of these cases were small children. The inner bark was given to the patients in a dose of from 4 to 8 grains, an hour or two before the expected chill, repeating the dose 2 or 3 times, each time anterior to the anticipated chill. Three doses were usually required; in one case, only 1 dose was given, and in two others, 4 doses were taken before the chills disappeared. The most marked influence was in an obstinate case, tertian, invariably attended during the attacks with gastric pain and irritability, and neuralgic pains in the superior extremities; the first dose afforded much relief, and since the third dose the patient has been entirely free from any symptoms of the malady, and has, for the first time in several years, passed an autumnal season without any chills, while neighbors were suffering more or less severely from them. Professor Locke has used it successfully in *chronic intermittent*, but thinks it not so efficacious in the acute forms. Prof. J. M. Scudder also had considerable success with it. He regarded it an excellent tonic and restorative when the secretions are depraved, the bowels irregular, tongue inclined to be dirty, skin dirty and sallow, and the urine depositing a sediment (*Spec. Med.*, 69). Many physicians have reported favorably as regards its antiperiodic virtues, having successfully used it where quinine had failed. From the fact that it corrects depraved states of the blood in malarial disorders, Webster contends that it should not be termed an antiperiodic, but rather a corrective of malarial cachexia. Dr. John Fearn favors its use in *chronic malarial poisoning*, and gives as its specific indications: Tongue dirty, skin sallow, and urine turbid, with periodicity. Gastro-intestinal disorders, depending upon chronic malaria, such as *lienteric diarrhæa*, *dysentery*, and *atonic dyspepsia*, are reputed to be cured by it. According to Dr. R. E. Kunze, of New York City, this bark possesses slightly narcotic, cerebro-stimulant, antiperiodic, febrifuge, and tonic properties; he has used it with success in several cases of intermittent fever, though, from its peculiar effects in certain cases, he is rather inclined to consider its use contraindicated in "patients of a delicate and highly nervous organization." Among the patients with whom it has acted favorably, it not only checks the ague, but appears also to prevent its return, for the season, at least. The bark is very bitter, and produces different effects with different parties; among these effects may be named a persistent disagreeable taste, more or less nausea or a sense of disgust, dizziness, pain in the forehead and occiput, tinnitus, weight in the epigastrium, etc. With many, the only appreciable symptoms noticed are the unpleasant taste left in the mouth and fauces, and the prompt disappearance of the chills. The dose of the bark, which should be well masticated, is from 2 to 8 grains; but

the more desirable form for administration and efficacy appears to be the powdered bark, in capsules, 2 to 5 grains every 3 or 4 hours; as a tonic, grain doses. Of the tincture the dose will vary from 10 to 60 minims every hour or two, and should be given on the days of the attack, commencing several hours before the expected chill. This is certainly an agent that should be thoroughly tested by the profession.

Specific Indications and Uses.—Chronic malarial cachexia and gastro-intestinal disorders depending thereon, with dirty, sallow, or tawny skin, and dirty, pasty tongue; the urine is turbid and cloudy, with urinary deposits. Periodicity, with exacerbations, and remissions, or intermissions.

Related Species and other Antiperiodics.—*Alstonia spectabilis*, R. Brown. *Poelt-bark*. Java. Contains, according to Hesse, a much larger proportion of alkaloids than the other *Alstonias*. Yields *echitamine* and *alstonamine* (alstonine of Scharlée). *Wrightia antidysenterica*, R. Brown (*Holarrhena antidysenterica*, *Nerium antidysentericum*, Linné). *Nat. Ord.*—*Apocynaceæ*. *Conessi bark*, *Codaga pala*, *Tellicherry bark*. A rusty-hued, spongy, bitter bark, formerly much employed on the continent in *dysentery* and *diarrhœa*, and still in use in India. Haines (1858) extracted an impure alkaloid from it, which Stenhouse afterwards obtained pure. The former named it *conessine*; the latter, *wrightine*. Its composition has been variously given, and the name *kurchicine* has also been applied to it. It is amorphous, white, bitter, soluble in alcohol, diluted acids, and ether. As obtained and put on the market by Merck, it forms delicately interlaced crystalline masses. *Holarrhena africana* contains a similar alkaloid, and is used in Africa as a remedy for *dysentery*.

Picrorhiza kurroa, Royle. India. The root of this plant, known as *kali kutki*, is used in India as a mild aperient and bitter stomachic. According to Dymock (*Mat. Med. Western India*), it is a powerful tonic, and is of much value as an antiperiodic, its slightly laxative qualities rendering it doubly efficient.

Echites species.—Several species of *Echites* are used in India and South America. They and their uses are as follows: *Echites syphilitica*, Linné filius. Surinam. Used in *syphilitic disorders*. *Echites antidysenterica*, Roxburgh, *Echites pubescens*, Buchanan, *Echites longiflora*, Defontaines, *Echites Curura*, Martius, and *Echites insignius*, Sprengel; bark used in *dysentery* and *diarrhœa*. *Echites caryophyllata*, Roxburgh; leaves used in *arthritic febrile complaints*. *Echites malabarica*, Lamarck; root employed in *fevers*, and leaves topically to *carbuncles*.

ALSTONIA SCHOLARIS.—DITA BARK.

The bark of *Alstonia scholaris*, R. Brown.

Nat. Ord.—*Apocynaceæ*.

COMMON NAMES: *Dita bark*, *Devil tree of India*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 173.

Botanical Source.—*Alstonia scholaris* (Dita bark), is found throughout tropical Eastern Asia and the Malayan Archipelago (Bentham). It is a large

Fig. 16.

Bark of *Alstonia scholaris*.

tree, with smooth, entire, thick leaves disposed in whorls. The flowers resemble those of *Alstonia constricta*, but differ in having corolla tubes about three times as long as the calyx, and shorter pubescent lobes. The pods are slender and over a foot long. Don says it is a native of the East Indies and the Moluccas; the bark met with in commerce comes from the Philippine and neighboring islands, and is the portion used in medicine. The local name of the bark is *satureen*.

As a remedial agent *dita* is old, having been mentioned, it is said, by Rheede (1678), and Rumphius (1741).

Description.—*Dita bark* is about $\frac{1}{2}$ inch thick, and is found in market in irregular sizes from 1 to 2 inches wide, and from 3 to 6 inches long. Externally it is of a mottled pinkish or brownish and white color, rather smooth, but marked by shallow fissures which are raised upon the edges and scarcely extend through the corky layer. The cork, a very thin layer, represented by the dark edge of the section *b* of our engraving, is brown. Internally, the color of the bark is light, slightly striated with yellowish layers or grains. In texture it is granular and brittle, resembling wild cherry bark from old trees. The taste is slightly bitter, free from astringency, not unpleasant, and may be compared to the aftertaste of wild cherry bark, and in like manner the bark is gritty between the teeth.

Chemical Composition.—According to Husemann, Scharlée, in 1863, published an article on the preparation of an alkaloid which he named *alstonine*. Gruppe found in it about 2 per cent of a substance which possessed febrifuge powers, and he named it "ditain." It was prepared, according to Hildwein, in a manner similar to that used in making quinine; it is not an alkaloid, but a mixture of substances, as was verified by Gorup-Besanez, who found it to contain a crystallizable substance possessing the properties of an alkaloid. Jobst and Hesse (1875), separated the true alkaloid, *ditamine* ($C_{18}H_{19}O_2$), from the bark, as a white amorphous powder, slightly bitter, soluble in ether, chloroform, benzene, and alcohol, being alkaline in reaction from the latter solution. It forms soluble salts, with diluted acids, which are very bitter; it dissolves with a reddish color, in sulphuric acid, and yellow in nitric acid, turning dark green at first when heated, then orange-red, with evolution of fumes of the same color. It was obtained only in about 0.02 per cent of the bark operated upon, and on this account can never be expected to come into general use as a febrifuge. A second alkaloid, *ditaine* (crystallizable) was obtained by Harnack in 1877, for which Hesse, in 1880, found the formula $C_{22}H_{23}N_2O_4$, and changed the name to *echitamine*. Besides, Hesse discovered a brown amorphous alkaloid which he named *echitenine* ($C_{20}H_{21}NO_4$). In addition, there are present oxalate of calcium, fatty acid, crystallizable acid, and several fatty resinous substances called: *Echicaoutchin* ($C_{20}H_{21}O_2$); *echicerin* ($C_{20}H_{21}O_2$); *echitin* ($C_{20}H_{21}O_2$); *echitein* ($C_{20}H_{21}O_2$); *echiretin* ($C_{20}H_{21}O_2$). These substances closely resemble resins obtained from other sources. Doubtless, the bark, if employed in medicine, will be either used in substance or in the form of tincture or fluid extract, as the proximate principles can not become of much commercial importance.

History.—In Ceylon coffins are made of this light wood (*Treasury of Botany*). According to Drury, the name "scholaris" is derived from the fact that its planks, when sanded, were used by school children for tracing letters. It is largely used in India for skin disorders (Dutt, *Hindu Mat. Med.*), and as a febrifuge. According to Graham, the natives have a superstitious reverence for this tree, believing that all the forest trees assemble once a year to pay homage to it (Dymock). This bark is largely used by the natives of India (where it is official in the *Pharmacopœia*), as a remedy for bowel disorders, and to restore the tone of the gastrointestinal tract after exhausting sickness, as from fever (Maiden). Woolen and cotton cloths are dyed various shades of yellow with this bark (Baron von Mueller's Exhibit, Melbourne, 1866).

Action, Medical Uses, and Dosage.—Dita bark has been efficaciously employed in *malarial fever*; it does not, however, appear to be as prompt nor as active in its influence as the *alstonia constricta* bark, requiring to be used in somewhat larger doses. *Alstonia scholaris* has some reputation as a remedy for *dysentery* (Bancroft, Bixby). Its alkaloid may prove more efficient should it ever become more largely and less expensively prepared. Dose of the fluid extract, 1 to 4 fluid drachms.

ALTHÆA (U. S. P.)—ALTHÆA.

"The root of *Althæa officinalis*, Linné"—(U. S. P.).

Nat. Ord.—Malvaceæ.

COMMON NAME: Marshmallow.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 35; Woodville, *Med. Bot.*, 198.

Botanical Source.—*Althæa officinalis* is a peculiarly soft and downy, hoary, green herb, having a tap-shaped, rather woody root. It has several erect, simple stems, from 2 to 5 feet in height, round, leafy, tough, and pliant; the leaves are ovate or heart-shaped at the base, of various breadths, plaited, 5-ribbed, unequally serrated, petioled, soft and pliable, and more or less deeply divided into 5 acute lobes. The flowers are large, in very short, dense, axillary panicles, rarely solitary, of a delicate, uniform, bluish color. The involucre has 8, 9, 10, or 12 divisions. The 1-seeded fruit is formed of numerous capsular carpels, closely and circularly arranged around the axis.

History and Description.—This perennial herb is found commonly on the banks of rivers, and in salt marshes. It is indigenous to Europe, and portions of Asia, in some parts of which it is cultivated in great quantities for medical use; and moist, sandy soils are preferred. It flowers from July to September. The whole plant, but especially the root, abounds with mucilage. Although the plant grows to some extent in the United States, the root is principally obtained from Europe for medical purposes, that which comes from Germany being much whiter but not so thick as that from the south of France. As found in commerce, the root is in pieces 3 or 4 inches long, or more, roundish, about $\frac{1}{2}$ inch in diameter, with a feeble odor and very mucilaginous taste. It should be chosen plump, and little fibrous; with a very white surface, well cleared of its yellowish epidermis, downy from the mode of dressing it with files; and possessing no moldy, acid, nor musty odor, and no acid taste. Sometimes it is met with divided lengthwise. The plant contains nearly 20 per cent of mucilage—(Ed. Duncan). Both the flowers and leaves are occasionally employed by the Europeans. The root should be gathered in the early spring or autumn of the second (not later than the third) year's growth, and only the fleshy portions retained, the older, woody roots being valueless.

The *Pharmacopœia of the United States* directs that *Althæa* shall conform to the following description: "In cylindrical or somewhat conical pieces, from 10 to 15 Cm. (4 to 6 inches) long, 10 to 15 Mm. (.039 to .059 inch) in diameter, deeply wrinkled; deprived of the brown, corky layer and small roots; externally white, marked with a number of circular spots, and of a somewhat hairy appearance from the loosened bast fibres; internally whitish and fleshy. It breaks with a short, granular, and mealy fracture, has a faint, aromatic odor, and a sweetish, mucilaginous taste"—(U. S. P.).

Chemical Composition.—*Althæa*-root contains starch, pectin, mucilage, sugar, lignin, calcium phosphate, fixed oil, a viscid material, and *asparagin* (A. Buchner). *Asparagin* ($C_4H_7N_3O_6 \cdot H_2O$), is a colorless, crystallizable body, without taste or odor. Ether and alcohol do not dissolve it, but it is extracted from the root with water, from which it may be crystallized by concentrating the solution. Its reactions prove it to be *amido-succinamic acid*, having the formula: $CO_2N \cdot CH_2 \cdot CHNH_2 \cdot CONH_2$. When boiled with acids or alkalies, it splits into ammonia and *amido-succinic acid* or *aspartic acid* ($C_4H_7NO_4$). *Asparagin* is distinguished by its optical activity, being lævo-rotatory in aqueous solution, which changes to dextro-rotatory by the action of acetic acid. *Asparagin*, when pure, is stable in solution, but is susceptible to fermentation in the presence of albuminoid substances, whereby it is converted into ammonium succinate.

Asparagin was discovered by Vauquelin and Robiquet, in 1805, in the juice of the asparagus plant, and in the marshmallow root, as *althæin*, by M. Bacon, in 1826. It is identical with *agedoite*, found by Caventou in liquorice root (*Jour. de Pharm.*, xiv., 177), and is found in many other plants, e. g., comfrey, dahlia, potatoes, the roots of *Robinia Pseudacacia*, etc. The mucilage (free from starch) of the root is extracted with cold water; the starch by boiling water.

Action, Medical Uses, and Dosage.—The root of this plant, as well as of each of the below mentioned plants described as substitutes, is demulcent and diuretic, and may be used indiscriminately, the one for the other. They will be found valuable, in the form of decoction, in diseases of the mucous tissues, as hoarseness, catarrh, pneumonia, gonorrhœa, vesical catarrh, renal irritation, acute dysentery, and diarrhœa. In strangury, inflammation of the bladder, hematuria, retention of urine, some forms of gravel, and indeed in nearly every affection of the kidney and bladder, their use will be found advantageous. Much use is made of them combined with equal parts of spearmint, in urinary derangements. They are likewise efficacious in gastro-intestinal irritation and inflammation. As the decoction soon decomposes, or becomes moldy or acid, it should always be made in small quantities, not more than 1 or 2 pints at a time, according to the temperature of the weather. Externally, marshmallow root is very useful in the form of poultice, to discuss painful, inflammatory tumors, and swellings of every kind, whether the consequence of wounds, bruises, burns, scalds, or poisons; and has, when thus applied, had a happy effect in preventing the occurrence of gangrene. The infusion or decoction may be freely administered.

Related Species.—*Althæa rosea*, Cavanilles (*Alcea rosea*, Linné). *Common garden hollyhock*. Native of China. Cultivated for its beauty in gardens. The flowers, capsules, and root are used for similar purposes as the marshmallow. The purple flowers are preferred, a concentrated infusion of which colors white bibulous paper a fast purple-blue, which is turned a blue-green by alkalis, and red with acids. The root contains a considerable amount of mucilage, and is sometimes used as an emollient and demulcent.

Althæa taurinensis, De Candolle. South Europe. Use, same as of *Althæa officinalis*.

Malva sylvestris, Linné. *Common mallow*. This is a perennial, hairy herb, sometimes called *High-mallow*; has a tapering, branching, whitish root, and an erect, round stem 2 or 3 feet high. Leaves alternate, deep-green, soft, downy, serrated, plaited, with 7 acute lobes, on hairy petioles; uppermost with fewer, but deeper and more acute lobes than the lower ones. Flowers large, numerous, of a shining purple, veiny, on simple, aggregate, hairy axillary stalks. Calyx 5-cleft. Petals 5, inversely cordate, thrice the length of the calyx. Stamens indefinite, monadelphous. Pollen large, whitish. Ripe carpels reticulated at the back.—(L.—G.).

Malva rotundifolia, Linné. *Low-mallow*, or *Round-mallow*, called by children who are fond of eating the fruit, *cheeses*; has a fusiform root and prostrate stem; leaves of a fine, delicate texture, roundish, cordate, or somewhat reniform, crenate, obtusely 5 or 7-lobed, on long, hairy petioles. Flowers pale-pink, deeply-notched petals, on aggregate, axillary peduncles. Fruit depressed-globose, composed of the numerous carpels arranged circularly (W.).

The *M. sylvestris* is a native of Europe, and is naturalized in this country, growing abundantly in fields, roadsides, and waste places, and flowering from May to October. The whole plant, especially the root, abounds in mucilage. The *M. rotundifolia*, a very common, troublesome plant, growing around dwellings and in cultivated grounds together with other species of this genus, possesses similar properties, and they may be substituted for each other. The herb and flowers are inodorous, with a weak, herbaceous, mucilaginous taste. Water extracts their mucilage, and acetate of lead precipitates the solution. The root and seeds may be also used, as they contain much mucilage. The blue infusion, or tincture of the flowers, is turned green by alkalis, and red by acids, thus forming an exceedingly delicate indicator. Mallows possess the properties common to mucilaginous herbs. An infusion forms an excellent demulcent in coughs, irritations of the air passages, flux, affections of the kidneys and bladder, etc. It may also be used in injection. The herb, bruised, forms a good emollient cataplasm to boils and inflammatory conditions of external parts. Low-mallows makes a good ointment for use on sores in horses.

Malva vulgaris, Fries. (*Malva neglecta*, Wallroth). Europe. Together with leaves of *M. sylvestris*, the source of German official *Mallow-leaves*.

Abutilon Arizense, Gærtner. (*Sida Abutilon*, Linné). *Indian mallows*. *Velvet leaf*. Indigenous to the Levant. Naturalized in Europe and the United States, where it is a common weed. Emollient and diuretic. Cultivated in China as a substitute for hemp.

Hibiscus Moscheutos, Linné. (*Hibiscus palustris*). *Marsh rose hibiscus*. U. S. Marsh hibiscus has a root very much resembling that of the Marshmallow, possesses exactly the same properties, and may be as effectually used. It is a tall, showy, perennial plant, growing in salt marshes, near salt springs, and on wet prairies, and flowers in August.

Hibiscus virginicus, Sweet weed. Marshes along the Atlantic from New York southward. Has the mucilaginous properties of the *Althæas*.

Hibiscus esculentus, Linné. (*Abelmoschus esculentus*, Guillemin and Perrotett). (See *Hibiscus*).

Abelmoschus moschatus, Moench (*Hibiscus Abelmoschus*, Linné). (See *Hibiscus*).

Hibiscus Rosa-Sinensis, Linné. *China rose*. The bark of the stem is reputed emmenagogue, while the root is employed in the Eastern world like Marshmallow. It is a cultivated species.

Hibiscus Sabdariffa, Linné. Africa. *Red sorrel*. Cultivated in tropical climes. It is known in the Mexico-Texan regions as *Jamaica*. The calyx, which contains mucilage, malic, tartaric, and possibly oxalic acids, in a free state, is the part employed.

Sida floribunda, Peru. Contains an abundance of mucilage. The leaves, which are thickly beset with minute, stiff spines, are reputed a mechanical vermifuge (Martinet).

Sida rhombifolia. Queensland hemp. *Jelly leaf*. Contains an abundance of mucilage, and is employed as a poultice and a remedy in respiratory complaints.

Species.—SPECIES PECTORALES (N. F.). *Pectoral species*. *Species ad infusum pectorale*. *Breast tea*. (German Pharmacopœia). *Formulary number*, 344: "Althæa, peeled, 8 parts; coltsfoot leaves, 4 parts; glycyrrhiza, Russian, peeled, 3 parts; anise, 2 parts; mullein flowers, 2 parts; orris root, 1 part. Cut, bruise, and mix them. *Note*.—Coltsfoot leaves are derived from *Tussilago Farfara*, Linné. Mullein flowers are from *Verbascum Thapsus*, G. Meyer. *Infusum pectorale* (pectoral infusion, or infusion of pectoral species), is made by infusing 1 troy ounce of the above preparation, in the usual manner, so as to obtain 10 fluid ounces of strained product"—(Nat. Form.). As the name of this preparation implies, it is employed by the Germans in various pulmonary complaints, attended with cough.

SPECIES EMOLLIENTES (N. F.). *Emollient species*. *Emollient cataplasm*. (German Pharmacopœia). *Formulary number*, 342: "Althæa leaves, mallow leaves, melilot tops, matricaria, flaxseed, of each, equal parts. Reduce them to a coarse powder, and mix it uniformly. *Note*.—Mallow leaves are derived from *Malva vulgaris*, Fries, and *Malva sylvestris*, Linné. Melilot tops are the leaves and flowering branches of *Melilotus officinalis*, Desrousseaux, and *Melilotus alissimus* Thuilliers"—(Nat. Form.). This is designed for the ready preparation of an emollient poultice for various inflammations, swellings, etc.

ALUMEN.—(U. S. P.)—ALUM.

I. ALUMEN, U. S. P. (ALUMINII ET POTASSII SULPHAS).

FORMULA: $\text{Al}_2\text{K}_2(\text{SO}_4)_4 \cdot 24\text{H}_2\text{O}$. MOLECULAR WEIGHT: 946.46.SYNONYMS: *Alum*, *Potash alum*, *Potassium alum*.

II. ALUMINII ET AMMONII SULPHAS.

FORMULA: $\text{Al}_2(\text{NH}_4)_2(\text{SO}_4)_4 \cdot 24\text{H}_2\text{O}$. MOLECULAR WEIGHT: 904.42.SYNONYMS: *Alum*, *Ammonia alum*, *Ammonium alum*.

Source.—These salts are double sulphates of aluminum and an alkali manufactured from clay, from alum stone (*alunite*), from cryolite, and from aluminous schist, or alum slate, often containing pyrites. Common alum (potash alum) is chiefly found in volcanic countries, in the earth of which it exists naturally.

Preparation.—Alum is prepared in several ways. Pipe-clay (aluminum silicate), which should contain but little iron, is calcined and then mixed with hot sulphuric acid until a paste-like magma results; the mixture then being exposed to the atmosphere, will be gradually changed to aluminum sulphate. If this be mixed with either sulphate of potassium or ammonium in solution, alum will be deposited in crystals. To render the combination of the acid less difficult, the clay is sometimes heated in a reverberatory furnace with from 10 to 20 per cent of charcoal or gas coke. Again, when *alum-stone*, which contains the elements of alum (potassium sulphate and aluminum sulphate), combined with hydroxide of aluminum, is roasted, thrown into piles, and kept moist for a number of months, it will be found to have been changed to alum, which may be readily obtained by lixiviation with water and then crystallized. This calcined *alunite*, or alum-stone, yields a very pure alum. To obtain it from *aluminous schist*, or alum slate, which is principally aluminum silicate (clay), containing iron sulphide, bitumen, and lime and manganese in small amounts, the slate, if dense, is piled in alternate layers with wood or coal, and slowly calcined; or if the slate be not too compact, the roasting is dispensed with and the slate is at once subjected to the process of weathering. The shale is crushed, thrown into heaps, and exposed to the air for an extended length of time—sometimes for years. By oxidation, iron sulphide is converted into ferric sulphate and sulphuric acid, which acts upon the aluminum silicate, converting it into aluminum sulphate. The mass is then lixiviated. To the concentrated solution, while hot, is added potassium chloride (obtained from waste in soap-boiling, and from nitre works), which combines with the iron sulphate, yielding chloride of iron and sulphate of potassium. The iron salt remains in solution while the alum formed separates as a powder when the liquor cools. The alum is then purified by recrystallizing several times, the last operation being conducted in large retainers, which may easily be taken apart so as to detach the alum crystals. This process yields potash alum. If, however, ammonium sulphate be used instead of potassium chloride, ammonia alum is the result. The ammonium sulphate is usually obtained from the refuse of gas works.

Alum is extensively made by treating the mineral, cryolite, with concentrated sulphuric acid, applying heat to it, and then washing out the sodium sulphate formed, with cold water. The resulting aluminum sulphate is dissolved in hot water, and to the solution is added ammonium or potassium sulphate. The alum is then crystallized. The only alum now recognized by the *U. S. Pharmacopœia* is the potash alum. Both alums in commerce contain a variable portion of iron, not more than 8 per cent, which may be detected by potassium ferrocyanide, which produces with the alum solution a bluish coloration.

Description.—The official Alum (potassium alum), is thus described by the *Pharmacopœia*: "Large, colorless, octahedral crystals, sometimes modified by cubes, or in crystalline fragments, without odor, but having a sweetish and strongly astringent taste. On exposure to the air, the crystals are liable to absorb ammonia, and acquire a whitish coating. Soluble in 9 parts of water at 15° C. (59° F.), and in 0.3 part boiling water; it is also freely soluble in warm glycerin, but is insoluble in alcohol. When gradually heated, it loses water; at 92° C. (197.6° F.), it melts, and if the heat be gradually increased to 200° C. (392° F.), it loses all its water of crystallization (45.52 per cent of its weight), leaving a

voluminous, white residue. The salt has an acid reaction on litmus paper"—(U. S. P.). Its density is 1.724. A very strong heat expels its acid. Either refuses to dissolve it. Alum in solution is precipitated by potassium and sodium hydrates; also by aqua ammoniac and alkaline carbonates. The precipitate, $\text{Al}_2(\text{OH})_6$ (see *Alumini Hydras*), is easily soluble in excess of potassium or sodium hydrate, but not of ammonium hydrate, forming *aluminates* of these metals ($\text{Al}_2\text{O}_3\text{Na}_2$ or $\text{Al}_2\text{O}_3\text{K}_2$), and may be reprecipitated by boiling the solution with ammonium chloride; also carbonic acid gas decomposes the aluminate. As the physical properties of both the ammonium and potassium alum are identical, a description of the one will answer for that of the other. The ammonium alum may be differentiated from the potassium alum by adding to it an excess of alkali and heating, whereupon ammonia gas will be evolved, which may be known by its odor. If the same be heated to complete redness, alumina is produced. If potassium alum be mixed with powdered charcoal and heated without access of air, in a flask or retort, an inflammable powder, capable of spontaneous ignition upon exposure to the atmosphere, is produced. This is known as *Homborg's pyrophorus*, and is a mixture of charcoal, potassium sulphide, and alumina. A solution of alum dissolves the metals usually dissolved by weak sulphuric acid. Ammonium alum has a density of 1.631 and contains 47.6 per cent of water of crystallization, which is completely expelled when heated higher than 205°C . (401°F).

Tests.—For *Alumen* (U. S. P.): "The aqueous solution of the salt affords, with ammonia water, a white, gelatinous precipitate, which is nearly insoluble in excess of ammonia. Another portion of the aqueous solution yields, with barium chloride T.S., a white precipitate, insoluble in hydrochloric acid. When a saturated solution of the salt is actively shaken with tartaric acid T.S., it affords, within half an hour, a white, crystalline precipitate. The aqueous solution of alum affords, with potassium or sodium hydrate T.S., a white, gelatinous precipitate, which is completely soluble in an excess of the alkali, and this alkaline solution should not evolve the odor of ammonia, even when heated (distinction from and absence of ammonium alum). A 5 per cent aqueous solution of the salt should not be affected by hydrogen sulphide T.S. (absence of copper, lead, or zinc), and 20 Cc. of this solution should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide T.S. (limit of iron)"—(U. S. P.).

ALUMEN EXSICCATUM (U. S. P.), *Dried Alum*. (*Alumen ustum*, *Burnt alum*). Formula: $\text{Al}_2\text{K}_2(\text{SO}_4)_6$. Molecular weight, 515.42. Preparation: Take "Alum, in small pieces, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; to make fifty-five grammes (55 Gm.) [1 oz. av., 411 grs.]. Place the alum in a shallow porcelain capsule so as to form a thin layer, and heat it on a sand-bath until it liquefies. Then continue the application of a moderate heat, with constant stirring, until aqueous vapor ceases to be disengaged, and a dry, white, porous mass is obtained, weighing fifty-five grammes (55 Gm.) [1 oz. av., 411 grs.]. When cold, reduce the product to a fine powder, and preserve it in well-stoppered bottles"—(U. S. P.).

Description: "A white, granular powder, without odor, possessing a sweetish, astringent taste, and attracting moisture on exposure to the air. It is very slowly, but completely, soluble in 20 parts of water at 15°C . (59°F), and quickly soluble in 0.7 part of boiling water. Its aqueous solution should respond to the reactions and tests of alum (see *Alumen*)"—(U. S. P.).

Action, Medical Uses, and Dosage.—**ALUMEN.** Alum corrugates and constricts the organic fibres, condensation probably being due to its power of coagulating albumen. It contracts the capillaries and coagulates the blood, and is therefore very useful in *passive hemorrhages*. In large doses it may act as a gastro-intestinal irritant. An ounce in solution killed a man, severe gastro-intestinal burning and pain being experienced and inflammation induced. In doses of from 30 to 60 grains, repeated every 3 or 4 hours, alum exerts a purgative influence; if these doses are repeated every 10 or 15 minutes, they will cause vomiting. From 5 to 20 grains, dissolved in some aromatic infusion, and repeated every 3 or 4 hours, will exert an astringent-tonic influence. As an astringent, alum has been used in *passive hemorrhages* and immoderate secretions, as in *diarrhæa* attending *typhoid fever*, *night sweats* of exhausting diseases, *passive bleeding from the lungs* (best by spray), *stomach*, *kidneys* or *uterus*, *fluor albus*, etc. In the inflammatory

stage of *gonorrhœa*, it will often be found useful in solution with an infusion of marshmallow. In *colic*, it has been found very useful when given in large doses, especially in that form of colic to which workers in lead are subject. In *spasm of the glottis* and *diseases of the throat*, accompanied with membraniform exudation, it is advised in emetic doses. It should only be used in croupous complaints when the secretions are free and loose. As an anti-spasmodic, it appears to exert a beneficial influence in *pertussis*. In several affections of the throat, alum, in solution, may be beneficially employed as a gargle, or it may be finely powdered, and blown upon the parts through a quill or small tube; thus used it will be found valuable in *sore throat*, *relaxed uvula*, etc. In the form of powder spray it will be found especially useful in many chronic mucous diseases, as in *congestion*, *catarrhal affections*, *chronic angina*, *thickening of the mucous tissue*, etc. Its solution may also be used as a wash for *pyalism*, and as an injection in *gleet* and *leucorrhœa*, alone or conjoined with sulphate of zinc. It has likewise proved very useful in *purulent ophthalmia of infants*, and in the later stages of *conjunctival inflammation*. The crystal (pencil), once much employed in conjunctival diseases, is not much used at present. In *colica pictonum*, it may be given in doses of from 30 to 60 grains, every 3 hours; it mitigates all the unpleasant symptoms of this disease more promptly and permanently than any other remedy. Singularly, it will relieve some cases of *obstinate constipation*. These cases are chiefly those in which there is marked atony, due to habitual distension of the bowels with gas. R Alum, grs. ij to iij; aqua, flziv. Mix. Sig. Teaspoonful every 2 hours. It is often used externally, either in powder or solution, to check *bleeding from the nose*, *excessive menstruation*, and to check the *bleeding* from cut surfaces; it may be applied on lint, or on a small piece of sponge if used in solution. From 4 to 10 grains of alum to 1 ounce of water, is of sufficient strength for a collyrium. To use in the form of spray in *faucial*, *tracheal*, *laryngeal*, and *nasal affections*, a solution of from 4 to 15 grains of alum to 1 fluid ounce of water may be used. I have found much advantage from the use of the following preparation in troublesome *cough*, especially when attended with tickling or irritation of the fauces, larynx, etc.: Take of a saturated solution of alum, syrup of balsam of tolu, each, 2 fluid ounces; camphorated tincture of opium, 1 fluid ounce. Mix. The dose for an adult is a tablespoonful 3 or 4 times a day, or whenever the cough is very troublesome (Prof. John King, M. D.). *Vulvar pruritis*, *inflammation of the vulva* in the young, and *leucorrhœa* are well treated with alum. In the latter complaint use a solution of borax one day, and one of alum the next (Locke).

ALUMEN EXSICCATUM. Dried or burnt alum, (*Alumen ustum*), is principally used as a mild escharotic, to destroy *exuberant spongy granulations*, known as proud flesh. It differs from alum only in the absence of water, being therefore more powerful, and may, like it, be used in form of powder spray.

ALUM WHEY, is made by boiling alum with milk, in the proportion of 5 grains of the former to every fluid ounce of the latter, and then straining off the thin liquor (C.). It may be given internally, in *diarrhœa*, etc., in doses of from $\frac{1}{2}$ ounce to 1 or 2 ounces. Externally, applied over the eye as a poultice, it is very serviceable in inflammation of that organ.

ALUM CURD, is prepared by mixing 30 grains of alum with the white of an egg. It is of value in *conjunctival inflammations*, and as an application to the face when *poisoned by Rhus Toxicodendron*.

ALUMINI HYDRAS (U. S. P.)—ALUMINUM HYDRATE.

FORMULA: $Al_2(OH)_6$. MOLECULAR WEIGHT: 155.84.

SYNONYMS: *Aluminum hydroxide*, *Hydrated alumina*.

Source.—Aluminum hydroxide is found in ashes of cryptogamous plants, being most plentiful in certain lycopodiums. It occurs native in some rare minerals, as *gibbsite* ($Al_2(OH)_6$), and *diaspore* ($Al_2(OH)_2O_2$), the former in America, the latter in Europe. The alkalies and their carbonates precipitate salts of aluminum from solution; in this way aluminum hydrate is prepared for medicinal use. It may be obtained from cryolite as a by-product in the manufacture of *sul soda* (sodium carbonate) from this source (see *Sodii Carbonas*).

Preparation.—"Alum, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; sodium carbonate, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; distilled water, a sufficient quantity. Dissolve each salt separately in one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.] of distilled water, filter each solution, and heat it to boiling. Then having poured the hot solution of sodium carbonate into a capacious vessel, gradually pour in the hot solution of alum, with constant stirring, and add an equal volume of boiling distilled water. Let the precipitate subside, decant the clear liquid, and pour upon the precipitate two thousand cubic centimeters (2000 Cc.) [67 fl. 3, 302 M.] of hot distilled water. Again decant, transfer the precipitate to a strainer, and wash it with hot distilled water, until the washings produce not more than a faint cloudiness with barium chloride T.S. Then allow it to drain, dry it at a temperature not exceeding 40° C. (104° F.), and reduce it to a uniformly fine powder"—(U. S. P.). This formula was essentially elaborated by Prof. J. U. Lloyd (see *New Remedies*, 1879, p. 237).

Description and Tests.—Aluminum hydrate is a light, amorphous powder, white, insoluble both in water and alcohol. It remains permanent in a dry atmosphere, and is without taste or odor. It readily and completely dissolves in sulphuric and hydrochloric acids, and in caustic potash and soda solutions, forming aluminates in the latter cases. It loses about 34.6 parts of water of hydration when heated to redness (U. S. P.). Aluminum hydrate has the property of forming insoluble compounds with coloring matters, as for example, madder or cochineal; hence the use of aluminum salts in the preparation of lakes, e. g., carmine lake prepared from cochineal, and as mordants in dyeing fabrics. "A solution of 1 Gm. of aluminum hydrate in 20 Cc. of diluted hydrochloric acid should not at once assume a blue color on the addition of 1 drop of potassium ferrocyanide T.S. (limit of iron), and should not give more than a faint cloudiness with barium chloride T.S. (limit of sulphate). When dissolved in potassium or sodium hydrate T.S., it should yield no precipitate with hydrogen sulphide T.S. (absence of zinc or lead); and when boiled with 20 parts of water, and filtered, the filtrate should not leave more than a slight residue on evaporation (limit of alkali salts)"—(U. S. P.).

Action, Medical Uses, and Dosage.—Absorbent, desiccant, and protective. Like the oxides of bismuth and zinc, it may be applied to *inflammations, burns, and excoriations*, and some of the diseases of the skin; it is likewise feebly astringent, and, like magnesium oxide, it may be used in acid states of the digestive organs resulting in *diarrhoea* and *dyspepsia*. Dose: 3 to 6 grains.

Aluminum and Its Compounds.—Symbol: Al. Atomic Weight: 27.4. ALUMINUM or ALUMINIUM. This is the metallic basis of the earth Alumina (*Aluminum oxide*, Al_2O_3), and is widely distributed in the earth's crust, forming the basic part of common clay (aluminum silicate) and various double silicates containing potassium, sodium, and other metals, as, for instance, the feldspar or garnet group. The metal, however, is not readily obtainable from its compounds except by somewhat laborious processes. It was first isolated, in 1827, by Wöhler, by melting together metallic potassium and chloride of aluminum under exclusion of the air. St. Clair-Deville, in 1854, was the first to isolate the metal in large quantities, obtaining it by the action of sodium upon sodium-aluminum-chloride, this salt having the advantage over aluminum chloride of being less hygroscopic. The metal obtained in this process was naturally very expensive. Bunsen, in 1854, was the first to prepare aluminum by the electrolysis of aluminum chloride, and in recent years the electrolytic separation of aluminum has become the dominant mode of manufacture, the details of which are mostly kept secret. Aluminum may now be counted among the common metals, costing at present only 45 cents a pound, while in 1879 one pound was as high as \$20.

Aluminum is nearly as white as silver, malleable and ductile in the highest degree. When worked it appears to become harder, and its tenacity probably approaches that of iron. It may be hardened, and again softened, by annealing. Its specific gravity is about 2.600. It may be melted and run out into the air without being sensibly oxidized. It is a good conductor of heat, and, when pure, is completely unalterable in dry or moist air. If not contaminated with metallic sodium, of which it is liable to contain from 1 to 3 percent (Moissan, *Drug. Circ.*, 1890), it will not become tarnished, and remains bright by the side of freshly cut zinc and tin, while the latter lose their brilliancy. It is not acted upon by hydrogen sulphide. Cold water has no action upon it, but boiling water oxidizes it slowly at 100° C. (212° F.). Nitric acid, either concentrated or diluted (Wöhler), and diluted sulphuric acid, when applied cold are also said to be without action upon it. With hydrochloric acid it evolves hydrogen, and forms chloride of aluminum. When heated to redness in hydrochloric acid gas, dry and volatile chloride of aluminum is produced. It is also soluble in alkaline liquids. Aluminum is highly sonorous.

Great claims have been made for this metal, many believing it destined to supersede iron as a construction material; also that it will replace the metals now in general use in the making of household utensils. These enthusiasts, however, overlook the fact that it is soluble in alkalies, forming aluminates, with the liberation of hydrogen. Were it to become a kitchen utensil, the constant use of soap and alkaline solutions in common use for the cleansing of such vessels would gradually dissolve the aluminum utensils. Again, if employed for cooking, the use of common salt (sodium chloride), which is a common necessity in nearly all culinary processes, would be apt to have a disintegrating effect upon the metal (see e.g., data in *Comey, Dict. of Inorganic Solubilities*). It is, however, exceedingly useful in the manufacture of many ornamental articles, rivaling silver in its beauty. Its remarkable levity and freedom from oxidation renders it very valuable in the production of clocks, picture frames, etc. Some useful surgical and gynecological appliances are now made of this metal. Until recently, no method of soldering aluminum was known, but this now seems to have been accomplished. An alloy of zinc, tin, aluminum and phosphorus, is stated by Prof. J. Richards to make a good soldering material (*Drug Circ.*, 1894). An alloy, of golden color, known as *aluminium bronze*, is composed of copper 90 parts, aluminum 10 parts. Aluminum as a base gives rise to the alums and other medicinal salts.

Aluminum oxide (Al_2O_3).—This compound exists in the mineral *Corundum*, a substance almost as hard as the diamond, forming crystals of the rhombohedral form, and varying considerably in color. It has several modifications or varieties which are transparent and used as precious stones, their color, as a rule, giving them their distinctive appellations. Thus, we have the *Sapphire* (blue), the *Ruby* (red, by the presence of chromium), *Oriental topaz* (yellow), *Oriental amethyst* (violet), *Oriental emerald* (green). The well-known polishing powder, *emery*, known also as *Lapis smiridia*, or *Lapis myris*, or *Schmirgel*, is a coarser modification of corundum. Alumina, or oxide of aluminum, in grain doses of the 1x trituration, or 1 centesimal trituration, is indicated where the patient cannot pass the urine without great straining (*Scudder, Table of Spec. Ind.*).

ALUMINI ACETAS, Aluminum acetate ($Al_2[C_2H_3O_2]_6 + H_2O$).—This may be made by double decomposition of lead acetate and aluminum sulphate, when, by evaporation at a low heat, a styptic, gum-like product results, having acid properties. It may be prepared also by dissolving hydroxide of aluminum in acetic acid (cold). A solution (impure) is made by adding an aqueous solution of 5 parts of alum to an aqueous solution of 6 parts of lead acetate. This salt is a valuable antiseptic and antiputrefactive agent. In its general action it resembles alum. It removes the odor of foul secretions, as sweat, etc., and has been employed as an embalming liquid. *Furuncles* of the external auditory meatus have been aborted by it. It is a valuable deodorant in *gangrene*, besides preventing consequent *pyemia*. Aluminum acetate is used as a mordant in dyeing.

ALUMINI CHLORIDI, Aluminum chloride (Al_2Cl_6).—This salt is prepared from a solution of hydroxide of aluminum in hydrochloric acid, which, when carefully evaporated, yields crystals containing 12 molecules of water. The anhydrous salt volatilizes; the hydrated salt decomposes when heated. It is dissolved by water and alcohol. A disinfecting solution is made by mixing solutions of alum (2 parts) and anhydrous calcium chloride (1 part), and filtering. On account of its lack of odor, it is especially useful in the sick room, as its deodorizing property is similar to that of acetate of aluminum, for which it may be substituted. Aluminum chloride finds a most useful application in organic synthesis (Friedel and Crafts).

CHLORALUM.—This deodorizer and disinfectant contains aluminum chloride to the extent of 15 per cent. Copper and arsenic, alum, alkaline sulphates, calcium chloride, and hydrochloric acid, are also ingredients. It has likewise been employed to check *hemorrhages*.

ALUMINI NITRAS, Aluminum nitrate ($Al_2(NO_3)_6 + 18H_2O$).—This salt is deliquescent, and difficult to obtain in crystalline form. Twenty parts of nitric acid are employed to dissolve such an amount of aluminum hydroxide as will be yielded by 33 parts of potash alum, or 31.5 parts of ammonia alum. This salt has been used in solution as an application to itching surfaces, as *pruritis vulvæ*.

ALUMINI ACETO-TARTRAS, Aluminum aceto-tartrate, Aluminum acetico-tartaricum.—Take basic acetate of aluminum, 5 parts, tartaric acid, 2 parts, water q. s. Solve and evaporate to dryness. The salt thus formed is in almost colorless, shining masses, amorphous, soluble in water, insoluble in alcohol, has an astringent, sour taste, and a weak, vinegar-like odor. An aqueous solution of it has been employed as an astringent and antiseptic. Its action is similar to that of acetate of aluminum. It is nonpoisonous, and has been employed in *ozena* and other offensive conditions. The *aceto-glycerinate* of aluminum has similar medical properties.

ULTRAMARINE.—An Asiatic mineral known as *Lapis lazuli* (*lazulite*), formerly furnished this pigment. Lazulite is a compound of aluminum and sodium silicate with sodium polysulphide. At the present time it is artificially produced by the ton, the color of the artificial product exceeding in beauty even that prepared from the mineral. Several colors are prepared, and known as *white*, *green*, *violet*, *red*, and *blue ultramarines*. Ultramarine is made by heating together a mixture of white clay with sodium sulphate and carbonaceous material in crucibles; a variety richer in silica is obtained by heating clay with finely ground quartz sand, soda, sulphur, and colophony in muffled furnaces; a blue product thereby at once results. The composition of the artificial product is not definitely known. The blue variety is largely employed in neutralizing the yellowness of paper, sugar, starch, and other materials. Ultramarine was first observed, in 1814, by Tassaert, in the black-ash furnaces of glass works, and found identical with lapis lazuli by Vauquelin. It was first prepared artificially, simultaneously by Guimet and by Gmelin, in 1824, the investigation being carried on at the instance of the French government, which offered a prize therefor. Ultramarine is easily distinguished

from any other blue pigment by the fact that it evolves hydrogen sulphide when treated with acids, becomes discolored and deposits sulphur.

Bolus, Bole.—This term has been applied to various argillaceous earths in times past. They are substances composed chiefly of aluminum silicate. All of them are unctuous to the touch, will adhere to the tongue, break with a shell-like fracture, and are soft enough to be easily scraped off with any cutting instrument. Though not soluble, they gradually form, with water, a paste-like mass. They have received different names, and are distinguishable by their colors, thus:

Bolus alba, or *Terra alba*, *Argilla*, a white form, containing, in addition to aluminum silicate, magnesium oxide in small amount, as well as a very little iron.

Bolus Armena, *Armenian bole*, *Bolus rubra*, *Argilla ferruginea*. Brownish-red in color, caused by the quite large amount of ferric oxide present. It received its name from Armenia, the country in which it was first produced. It is now found in various European localities. At one time this variety, and the one following, were highly prized under the name *terre sigillite*, so called from the fact that circular cakes of them could be impressed with a seal.

Terra lemnia, *Lemnian bole*. Almost identical with Armenian bole, but containing less ferric oxide, being yellow in color.

Bolus Veneta, or *Venetian red*, is an ochery body of a dull-red color, employed in painting.

Creta rubra, *Red chalk*, *Reddle*, *Rubrica fabrilis*. This occupied a place between *red ochre* and *bole*. It is of a deep-red color, is firm and dense in texture, will soil the hands, and leave upon paper a bright-red mark when drawn over it. Its red color is due to iron. It is sometimes made into crayons and used to draw upon wood, stone, and other hard substances. All of the foregoing have been employed medicinally, being prepared by pulverization and elutriation. Bole was employed by the ancient Romans and Greeks, but is very little used in medicine at the present time, though occasionally employed in Europe. It is astringent and absorbent. The dose is from 5 to 10 grains. Internally it has been used in *relaxed conditions of the alimentary tract*, in *hemorrhagic states*, and *pulmonary affections*. It was used locally in many conditions requiring an absorbent astringent. Armenian bole is sometimes used to color dentifrices.

TERRA TRIPOLITANA, *Tripoli*.—A whitish, pale-straw or yellowish-colored earth, sometimes even brownish or reddish, presenting a clayey aspect, though differing from clay in not forming a paste when rubbed with water, and in having rough and hard particles. It is usually easily broken, and will often adhere to the tongue. It is employed in scouring and polishing metallic surfaces. A variety known as *Venetian Tripoli* is said to come from Corfu. Tripoli is sometimes artificially prepared by calcining argillites.

SIENNA, *Terra di sienna*.—A smooth, glossy, clayey mineral, light in weight but very compact and fine in texture, having a yellow-brown color tinged with orange. This is *Raw sienna*. When burned it is known as *Burnt sienna*, and has a red-brown color. Both varieties are used as pigments, the best grades coming from Italy.

KAOLIN, *Fullers' earth*, *Porcelain clay*. A white clay in the form of a powder, which appears unctuous when wet. It is nearly pure hydrated aluminum silicate, generally answering to the formula $Al_2(SiO_3)_2 + Al_2O(OH)_2$, and is formed by the weathering of feldspar minerals.

PUMICE STONE, *Pumey*, *Pumex*.—A light, porous, stone-like substance, most of which comes from near Lipari. As it is found near volcanoes, it is regarded as a product of volcanic eruption, the spongy texture being produced by the presence of watery vapor in the hot, fluid lava. Pumice stone is of great value in the arts, being employed either whole or in powder, as a polishing substance for metals, glass, stone, and particularly in giving a smooth surface to painted wood-work, as to carriage bodies, etc.

ALUMINI SULPHAS (U. S. P.)—ALUMINUM SULPHATE.

FORMULA: $Al_2(SO_4)_3$. MOLECULAR WEIGHT: 342.06.

Crystallized, $Al_2(SO_4)_3 \cdot 16H_2O$. Molecular weight, 628.9.

Preparation.—This salt is prepared on a large scale from China clay, by roasting the clay and then digesting it in diluted sulphuric acid, the solution being permitted to stand until clear. It is then decanted from the insoluble matter (silica and undecomposed alumina), and evaporated until it thickens upon cooling. As thus prepared, it is often known as *concentrated alum* (*alum cake*), and is used mainly as a mordant, and also to give weight to paper. The composition of anhydrous aluminum sulphate is represented by $Al_2(SO_4)_3$. The hydrated salt, $Al_2(SO_4)_3 \cdot 16H_2O$, was official in the *United States Pharmacopoeia* (1870); the former process of which forms precipitated trihydrate of aluminum (AlH_3O_3 , or $Al_2(OH)_6$), by the decomposition of sulphate of aluminum and ammonium, by means of sodium carbonate; sulphates of sodium and ammonium remaining in solution, and carbonic acid gas being evolved. It is intended that the precipitated aluminum hydrate be freed from soluble sulphates by washing, then united with sulphuric acid, and the solution evaporated to dryness, whereby

crystallized aluminum sulphate, $\text{Al}_2(\text{SO}_4)_3 + 16\text{H}_2\text{O}$, is obtained. Practically, it will be found that the water in which the salts (carbonate of sodium and the alum) are dissolved by the U. S. P. is insufficient, inasmuch as the solution of the alum may be troublesome to make, and when obtained, the two solutions are so concentrated that the hydrate is deposited in lumps, difficult, if not impossible, to free from contaminating sulphates by the subsequent process intended for washing.

The formula of the U. S. P. (1870) has been referred to here because we think the process an objectionable one, and would present the following as an improvement upon it (see *New Remedies*, August, 1879, p. 237):

Dissolve 4 troy ounces of alum, and the same amount of carbonate of sodium, each separately, in 4 pints of hot distilled water; pour the alum solution, in a small stream, with constant stirring, into the soda solution in a capacious porcelain dish, and bring the mixture to a fair boil. Then cool and pour the mixture upon a muslin strainer; when drained, return the precipitate to the dish, and mix thoroughly with a gallon of water, then strain, as before. Repeat the operation; then almost dissolve the gelatinous precipitate by means of diluted sulphuric acid, and filter the solution; evaporate it upon a water-bath, with stirring, until a dry salt remains. In case there is an excess of acid, it will be impossible to dry the salt; therefore we advise the use of not more than 1 troy ounce of sulphuric acid, thus insuring complete saturation. The excess of aluminum hydrate will remain upon the filter.

Description.—"A white, crystalline powder, without odor, having a sweetish, and afterward astringent taste, and permanent in the air. Soluble in 1.2 parts of water, at 15°C . (59°F .), and much more freely in boiling water, but insoluble in alcohol. When gradually heated to about 200°C . (392°F .), it loses its water of crystallization (45.7 per cent of its weight). The salt has an acid reaction on litmus paper"—(U. S. P.).

Sulphate of aluminum prepared as above, may contain traces of the sulphates of sodium and ammonium, which, however, is not a serious objection, unless in larger amount than is possible with the process we have given. It crystallizes with difficulty, forming thin 6-sided crystals. According to Berzelius, it is soluble in 2 parts of cold water. It melts on heating, in its water of crystallization, and then swells, like alum, forming the anhydrous sulphate, $\text{Al}_2(\text{SO}_4)_3$. At a red heat, it decomposes, the residue being alumina.

"The aqueous solution of the salt yields, with barium chloride T.S., a white precipitate insoluble in hydrochloric acid; and with potassium or sodium hydrate T.S., a white, gelatinous precipitate which is soluble in an excess of the alkali, but is again separated on the addition of a sufficient amount of the ammonium chloride T.S. A filtered, 10 per cent aqueous solution of the salt should not be affected by hydrogen sulphide T.S. (absence of copper, lead, or zinc), and should not become more than faintly opalescent within five minutes after the addition of an equal volume of decinormal sodium hyposulphite V.S. (limit of free acid). 20 Cc. of a 5 per cent aqueous solution of the salt should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide T.S. (limit of iron). If 1 Gm. of the salt be gently heated with 5 Cc. of potassium or sodium hydrate T.S., the liquid should not evolve the odor of ammonia"—(U. S. P.).

Action and Medical Uses.—Sulphate of aluminum is employed as a local application in cases in which a stimulating, astringent, or antiseptic action is required. From 4 to 6 pounds of the salt dissolved in 1 gallon of water, and the solution injected into the cadaver, in the usual way, will preserve it in the dissecting room for from 18 days to 2 or 3 months, according to the temperature of the weather (Gannal). A solution consisting of from 75 to 240 grains of this salt in 3 fluid ounces of water, has been found exceedingly useful as a topical application to old ulcers, and in leucorrhœa with offensive discharge. A saturated solution, and more especially when in combination with zinc oxide, has been employed as a stimulant or gentle caustic in tonsillar enlargements, polypus of the nose, affections of the uterine cervix, mother's mark, obstinate ulcers, chronic catarrh, and in other chronic diseased conditions of mucous tissues; it may be applied every day in form of spray or with a camel's hair pencil. A "benzoinated solution of aluminum," diluted with from 25 to 64 times its weight of water, forms an excel-

lent application in *chronic nasal discharges*, in *ulcerated conditions of the os uteri*, as well as in *offensive vaginal discharges*; it may be used by injection, or in the form of spray. This benzoinated solution is prepared by dissolving 4 ounces of aluminum sulphate in 8 fluid ounces of water, then adding recently formed gelatinous alumina to saturation, and finally adding 8 drachms of coarsely powdered benzoin—the best article of benzoin, that in the form of whitish tears, being used for this purpose. This solution is kept at a temperature of from 64.4° to 66.7° C. (148° to 152° F.), for 6 or 7 hours, being stirred from time to time until, when filtered, it has attained the specific gravity, 1.260. It is then set aside in a cool place for 6 or 7 days, until alum crystals are precipitated, and the solution has acquired a balsamic odor and taste, with astringency.

AMARANTHUS.—AMARANTH.

The leaves of the *Amaranthus hypochondriacus*, Linné.

Nat. Ord.—Amaranthaceæ.

COMMON NAMES: *Amaranth*, *Prince's feather*, *Lovely bleeding*, *Red cockscomb*.

Botanical Source and History.—An annual herb, with a stout, upright stem, growing from 3 to 4 feet high, bearing oblong, lanceolate, mucronate, green leaves, having either a red-purple spot, or tinged with purple. The flowers, which are bright-red, are compactly clustered on erect, compound racemes. The whole plant is dark-red, or reddish-purple, with long, plume-like clusters. This plant is a native of the Middle States, and is cultivated as an ornamental plant in gardens. It bears deep, bright-red flowers in August. The leaves, which are the parts used, are also red, and yield their virtues to water.

Action and Medical Uses.—Amaranth is astringent. The decoction drunk freely is highly recommended in severe *menorrhagia*, and has also been found beneficial in *diarrhœa*, *dysentery*, and *hemorrhage from the bowels*. It has likewise been used as a local application in *ulceration of the mouth and throat*, in *leucorrhœa*, and as a wash to *foul, indolent ulcers*. It is scarcely used at the present day.

Related Species.—*Amaranthus melancholicus ruber* contains 16 and *Amaranthus atropurpureus* nearly 23 per cent of potassium nitrate (Boutin). *Amaranthus caudatus* contains oxalic acid.

AMBRA GRISEA.—AMBERGRIS.

SYNONYM: *Ambra cinerea*.

Source.—An odorous, fatty material, believed to be a morbid production of the *Physeter macrocephalus*, Linné, or *Sperm whale*. It is found in the intestines of the whale, where it is thought to be produced, and also excreted and floating in large masses upon the waters of the sea. A single whale has yielded over 700 pounds of ambergris (*Amer. Jour. Pharm.*, 1859). The manner of production of ambergris is not definitely known, though it is supposed to be derived from the fatty matter of certain cephalopods consumed as food by the whale.

Description.—Ambergris occurs in irregular, wax-like masses, of a grayish or grayish-brown color, streaked or mottled, and opaque. Its density is less than that of water; it becomes soft and waxy by the warmth of the hand, but when cold is friable. It is also inflammable, and when heated is almost completely volatilized. Its odor is peculiar and fragrant. Ambergris has little or no taste. It is subject to adulteration, but may be distinguished by its physical characters.

Chemical Composition.—The chief constituent (80 to 85 per cent) of ambergris is *ambrein* (Pelletier and Caventou), a fatty body bearing some resemblance to cholesterin. It may be obtained in shining, white, needle-like crystals, odorless and tasteless. According to an analysis by John, in 1818, it also contains coloring matter, balsamic substances, sodium chloride, and benzoic acid.

Medical and Other Uses.—This substance has been employed as a stimulant to the circulatory and nervous systems. On account of its supposed selective affinity for the generative apparatus of the female, it has been given in

hysterical disorders of a spasmodic character. Musk, castor, and like animal drugs, as well as valerian, have been frequently given in conjunction with it. It has likewise been employed in *low grades of fevers*. The dose is from 5 to 20 grains in substance, or in solution in ether. It is more generally used in the preparation of perfumes. Ambergris was formerly employed in cookery.

TINCTURA AMBRÆ.—Finely triturate with well-washed sand 10 parts of ambergris; then macerate the powder in 100 parts of alcohol (80 per cent). This tincture is often employed in fixing the odors of delicate, volatile perfumes.

AMBROSIA TRIFIDA.—TALL AMBROSIA.

The leaves of the *Ambrosia trifida*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: Tall ambrosia, Great ragweed, Horseweed, Horse cane, Richweed, Wild hemp, Bitterweed.

Botanical Source.—*Ambrosia trifida* is a rough, hairy, herbaceous, annual plant, with an erect, branching, furrowed stem, from 5 to 10 feet in height. Its leaves are opposite, from 4 to 7 inches broad, scabrous and hairy, with three large, deep lobes which are oval, lanceolate, acuminate, and closely serrated; the lower leaves are often 5-lobed. The petioles are narrowly winged and ciliate; racemes often paniculate. The flowers are mean and obscure, in long, leafless spikes, axillary and terminal. The fruit (fertile involucre) is turbinate-obovoid, with a short, conical-pointed apex, 6-ribbed, the ribs terminating in as many cristate tubercles. It has a variety called *Ambrosia trifida*, var. *integrifolia*.

History.—This plant grows in low grounds and along streams, from Canada to Georgia, and west to Louisiana and Arkansas, bearing greenish-yellow flowers in August. It is much in use among farmers, for the "slabbers" in horses, effecting a cure in a few hours. It has a spicy, pleasant, aromatic taste, slightly resembling ginger, and imparts its properties to water. According to Rafinesque, the aborigines used it to make a sort of hemp and ropes.

Action, Medical Uses, and Dosage.—This plant is slightly stimulant, astringent, hemostatic, and antiseptic. Useful in decoction as an injection in *leucorrhœa*, *prolapsus uteri*, *chronic gonorrhœa*, and *gleet*; also valuable as a collyrium, in *ophthalmia*, and as a wash or gargle—with its internal use also—in *nursing sore mouth*. It will be found an excellent application to mercurial, and all other *ulcers* of a fetid or gangrenous character. As a remedy for *mercurial salivation*, used every half hour as a wash, it is said to be prompt and efficacious. Internally, the decoction is useful in *fevers*, attended with a disposition to *putrescency*, *diarrhœa*, and *dysentery*. It has been successfully employed in *bleeding from the nose*, and other *hemorrhagic discharges*, where the flow is small in amount. It has also been employed for the relief of *after-pains*, for *hysteria* and other *nervous disorders*. Dose of the decoction (tops 3ss, aqua Oj) from 1 to 2 fluid ounces.

Related Species.—*Ambrosia artemisiifolia*, Linné (*Ambrosia elatior*), *Roman wormwood*, or *Ragweed*, has a slender stem rising from 1 to 3 feet high, much branched, and pubescent when young; leaves opposite, the upper alternate, twice pinnatifid, smoothish above, paler or hoary beneath; barren flowers small, green, in terminal racemes, or spikes loosely panicked; fertile ones sessile about the axis of the upper leaves; fruit obovoid, or globular, pointed, armed with about 6 short acute teeth or spines (W.—G.). It is sometimes called "hog-weed," as but few animals excepting the hog will eat it. Cows occasionally partake of it, and it imparts to their milk a bitter taste which remains in butter made from the tainted cream. When carelessly gathered with wheat it also imparts to the flour of that cereal a bitter flavor, rendering it unfit for bread-making. Schimmel & Co., in 1894, isolated by distillation from the blooming plant, an essential oil, of deep-green color, and specific gravity 0.870. It has an aromatic, not unpleasant odor. *Ambrosia trifida*, subjected to the same process, did not yield any volatile oil. Ragweed is highly recommended as a fomentation in recent *inflammation* from *wounds* or *injuries* of any kind. Made into a salve by bruising the green leaves, and simmering them in spirits and cream, it is very useful in *hemorrhoidal tumors*, and some forms of *ulcer*. It may be used as a tonic after *intermittents*, and to alleviate *mucous fluxes*. Dose: Specific *ambrosia artemisiifolia*, 1 to 10 drops every 1 to 4 hours. Infusion (tops 3ss, to aqua Oj), 1 to 2 fluid ounces. It is very common in all our fields, and would probably prove fully as efficacious, if not more so, than *A. trifida*.

AMMONIA.—AMMONIA GAS.

FORMULA: NH_3 . **MOLECULAR WEIGHT:** 17.01.

Source, History, and Preparation.—Ammonia was unknown to the ancients; it was discovered in a state of solution by Black, in 1756, and in the pure gaseous condition by Priestley, in 1774, who produced it by heating a mixture of lime and sal ammoniac, and collecting the ammonia over mercury. Priestley named it "*volatile air*." To the earlier chemists it was known as *volatile alkali*, in contradistinction to *fixed alkali* (caustic potash), and to *marine alkali* (caustic soda). The alchemists were acquainted with a volatile alkali found in the urine, from which sal ammoniac was obtained by Geber. Ammonia exists abundantly as the product of the decomposition of vegetable and animal matter, chiefly the latter. When hoofs, horns, bones, and other animal substances are subjected to dry distillation, ammonium compounds are formed. The ammonia thus obtained has the name, *spirits of hartshorn*. The atmosphere contains a small amount of ammonium in combination with carbonic acid gas as carbonate. It has likewise been found in snow. In rain water it has been observed in combination with nitric and nitrous acids. The soil contains it, and it is especially abundant in natural beds of ammonium chloride, resulting from the decomposition of nitrogenous bodies. Most plants contain ammonium in combination. The principal source of gaseous ammonia at the present day is the *ammoniacal liquor* derived from the manufacture of illuminating gas. From this by-product it is obtained on a large scale by distilling with milk of lime, and neutralizing the distillate with hydrochloric acid; or the ammonia gas resulting from the distillation of gas liquor is allowed to pass into diluted sulphuric acid, from which it is crystallized as sulphate of ammonium. This salt is purified, and in turn is made to yield ammonia, by decomposition with the caustic alkalis. It may be obtained from any of the ammonium salts by heating them with potassic, sodic, or calcic hydroxides. A common method is to heat sal ammoniac (ammonium chloride) with lime: $2(\text{NH}_4\text{Cl}) + \text{Ca}(\text{OH})_2 = \text{CaCl}_2 + 2\text{H}_2\text{O} + 2\text{NH}_3$. Ammonia may also be prepared on a commercial scale by heating together in a retort (glass or iron), sulphate of ammonium and calcium hydroxide. When nitrous or nitric acid is acted upon by nascent hydrogen, ammonia results (see *Aqua Ammoniae*).

Description.—Ammonia is a volatile, colorless gas, having a characteristic, pungent odor, and imparting an acrid, alkaline taste. It is irrespirable, causing spasm of the glottis when an attempt is made to inhale it. Under ordinary atmospheric temperatures and pressures it is a permanent gas. At -40°C . (-40°F .), it is condensed to a colorless liquid, or at 15°C . (59°F .), under a pressure of 7 atmospheres, it may also be reduced to a very mobile, colorless liquid, lighter than water. At -75°C . (-103°F .), it freezes, forming white crystals. Its specific gravity is 0.59+. When ammonia is rendered liquid by pressure and then allowed to evaporate spontaneously in suitable vessels, an absorption of heat, *i. e.*, an excessive cold, is produced during evaporation. An important technical application is made of this principle in the manufacture of artificial ice. Ammonia is strongly alkaline, turning red litmus paper blue, and turmeric paper brown. It is very soluble in water, the latter dissolving about 700 times its volume of ammonia gas, forming hydroxide of ammonium (NH_4OH). Alcohol absorbs it. With acids it readily combines to form crystallizable salts, which, when heated, are either sublimed or decomposed. In contact with gaseous acids, *e. g.*, hydrochloric acid, it combines with them to form a dense smoke of white salts. It enters into the formation of many medicinal salts, and in solutions of definite strengths, it forms *Aqua Ammoniae* and *Aqua Ammoniae Fortior*. It burns in pure oxygen with the formation of water, nitric acid, and the liberation of free nitrogen. Animal structures are irritated and inflamed by this gas. Ammonia gas may be easily recognized by its characteristic odor, and by the black coloration it imparts to a strip of bibulous paper saturated with a solution of mercurous nitrate, a compound, $\text{Hg}_2\text{NH}_2\text{NO}_3$, being formed. An alcoholic solution of ammonia (10 per cent) forms the official *Spirit of Ammonia* (see *Spiritus Ammoniae*).

Action and Medical Uses.—(See *Aqua Ammoniae*).

AMMONIACUM (U. S. P.)—AMMONIAC.

"A gum resin obtained from *Dorema Ammoniacum*, Don"—(U. S. P.).

Nat. Ord.—Umbelliferae.

COMMON NAMES: *Gum ammoniac*, *Gummi-resina ammoniacum*.

Botanical Source.—The *Dorema Ammoniacum* is a glaucous green plant resembling opopanax. Its root is perennial and large, from which arise smooth stems, 8 or 10 feet high, and over 1 inch in diameter at the base, having petiolate, somewhat bi-pinnate leaves, about 2 feet long; the pinnæ are in 3 pairs, the leaflets are inciso-pinnatifid, with oblong, mucronulate, entire, or straightly-lobed segments, from 1 to 5 inches long, and $\frac{1}{2}$ inch to 2 inches broad. The petiole is downy, very large, and sheathing at the base. The umbels are proliferous and racemose, being composed of partial, globose umbels, on short stalks, often arranged in a spiked manner. The flowers are white, sessile, and immersed in wool. The fruit, which is elliptical and compressed, is also buried in wool, and surrounded by a broad, flat edge (L).

History.—From a want of correct knowledge of the plant furnishing this gum-resin, it was formerly considered a *Ferula*, but specimens of the Persian plant having been investigated by Don, he ascertained that, although it was somewhat related to this genus, yet it differed from it in several characters; he therefore gave to it its present name. The plant grows on arid, exposed situations in several parts of Persia, and in the course of the summer it is replete with a lacteous, gelatinous juice, which is readily obtained. It prefers a soil abounding in silica. Mr. Jackson says: "It is remarkable that neither bird nor beast is seen where this plant grows, the vulture only excepted. It is, however, attacked by a beetle, having a long horn proceeding from its nose, with which it perforates the plant and makes the incisions whence the gum oozes out." Colonel Johnson states that "in the month of May, while the plant is soft, an insect of the beetle kind begins to puncture the stem in every direction with his proboscis," etc. Captain Hart gives a similar account. But Fontanier asserts that it flows naturally, and is gathered in June. It is still supposed, however, to be sometimes furnished by other and dissimilar plants of Asiatic as well as African growth. It is asserted that in some places it is collected after the manner of obtaining asafetida. Around the plant, imbedded in the soil, are often formed tears of the gum which have either exuded into the ground from the root, or have dropped from the punctured stems. From the fibrous root-crown an inferior quality of gum is made to exude, which is dark in color. Gum ammoniac is mostly gathered by the peasantry in July. *Cake ammoniac* consists of tears of the gum admixed with the inferior brown exudation from the stem-base.

Description.—Gum ammoniac is not a gum proper, but a gum-resin; it is met with in tears and in lump. The tears vary in size from that of a small pea to that of a walnut. The lump ammoniac varies in appearance according to its quality. The best kind is composed chiefly of tears agglutinated together, though foreign impurities are frequently present. Ammoniac does not melt, but softens by heat, even the warmth of the hand; at a red heat it burns with a white flame. It may be partly dissolved by water, forming a white emulsion, which, upon standing, precipitates a resinous portion, leaving the supernatant liquid clear. Alcohol dissolves more than one-half, the remainder being a resin, insoluble in this liquor; and the soluble white resin is precipitated by the addition of water to the alcoholic solution. Ether dissolves resin and volatile oil, leaving the gum. Vinegar forms a smooth, uniform emulsion with it, but does not dissolve it. Mr. Hatchett found it soluble in alkalies. The *U. S. Pharmacopœia* thus describes ammoniacum: "In roundish tears, from 2 to 6 Mm. ($\frac{1}{4}$ to $\frac{1}{2}$ inch) or more in diameter; externally pale yellowish-brown, internally milk-white, brittle when cold, and breaking with a flat, conchoidal, and waxy fracture; or the tears are superficially united into irregular masses without any intervening, dark-colored substance. It has a peculiar odor, and a bitter, acrid, and nauseous taste. When triturated with water, it readily yields a milk-white emulsion"—(U. S. P.).

Chemical Composition.—Ammoniac has been analyzed by Braconnot, Buch-

olz, Hagen, Hirschsohn, Plugge, and others, and appears to consist of a large proportion of resin, with gum, bassorin, volatile oil, and water. The resin of ammoniac, amounting to 70 per cent, or less, is reddish or yellow, transparent, tasteless, but having the odor of the gum-resin; is brittle, softens in the hand, melts at 54.4°C . (130°F .), and is soluble in alcohol, and in excess of carbon disulphide. Ether separates it into an insoluble resin, and a resin soluble in sulphuric acid, and fixed and volatile oils. Alkalies form a cloudy solution. Nitric acid converts it into a yellow bitter matter, soluble in hot alcohol and water, and which will dye silk a fine yellow color, without being affected by chlorine. The gum is reddish-yellow, transparent, brittle, somewhat bitter, soluble in water, from which it is precipitated by subacetate of lead, and is converted into mucic, malic, oxalic, etc., acids, by the action of nitric acid. The oil, which may be obtained by distillation of the gum-resin with water, is transparent, colorless, and lighter than water. It is yielded to the extent of $\frac{1}{2}$ to $\frac{1}{3}$ per cent, has a specific gravity of 0.891 at 15°C . (59°F .), and boils between 250° and 290°C . (482° and 554°F .), (Schimmel & Co., *Semi-Annual Report*, Oct., 1893). The oil has dextrogyrate properties (*Pharmacographia*). Hlasiwetz and Barth (1864), obtained oxalic acid, resorcin, and a fatty acid of a volatile nature by fusing the gum-resin with caustic potash. It differs chemically from most of the allied gum-resins, in not yielding *umbelliferon* upon dry distillation. Neither does the drug contain sulphur.

Action, Medical Uses, and Dosage.—Gum ammoniac possesses stimulant, antispasmodic, and expectorant properties, and is said to purge in inordinate doses, as well as to produce vomiting, colic, and cutaneous eruptions. It has been found especially useful in chronic affections of the respiratory organs, especially among the aged, or those in whom the expectoration is scanty, as in *cough, asthma, etc.*, and has likewise been found advantageous in *profuse mucous discharges*, the result of weakness of the parts involved, as in *bronchitis or laryngitis, catarrh, leucorrhœa, etc.* It has also been advised in *hysteria*, but is inferior to some other of the fetid gum-resins, as *asafoetida*. Ammoniacum may be of service in small doses, in the *headache* resulting from disease of the frontal sinuses, in *affections of the optic nerve, in catarrhal affections of the throat, nasal passages, eyes, ears and stomach, mucous diarrhœa*, and in pains in the limbs accompanying disease of more or less of the mucous tissues generally. Applied externally in the form of plaster, it irritates the skin, frequently producing a papular eruption; and has been employed beneficially in this way, as a resolvent, to *indolent buboes, white swelling, tumor of the joints, chronic glandular enlargement, and other indolent swellings*. The dose is from 1 to 30 grains, in pill or in emulsion.

Related Species and Gum-Resins.—*Dorema Aucheri*, Boissier. Western Persia. This species is thought to furnish a portion of the gum ammoniac of commerce. The plant is known in the Kurdish vernacular as *Zuh*.

Dorema robustum, Loftus. Western Persia. Yields a gum unlike that from *Dorema Ammoniacum*, Don (*Pharmacographia*).

Ferula tingitana, Linné. North Africa and extreme West Asia. It is known in Morocco as *Keilh*, and its gum by the name *Fasay*. The latter is generally known, however, as *African ammoniac*. The gum differs from true gum ammoniac in having a comparatively weak odor, and in yielding *umbelliferon* (Hirschsohn). A peculiar acid, having the formula $\text{C}_{10}\text{H}_{10}\text{O}_6$, not present in the true gum, was obtained by fusing the Moroccan gum with caustic potash (Goldschmiedt). As with the true gum, resorcin was obtained by fusion with caustic potash. African ammoniacum occurs in dense, large, dark masses, formed by the agglutination of whitish, fawn-colored, or light-greenish tears, some specimens containing a considerable amount of foreign admixtures. It has a persistent, faintly-acrid taste, and is principally used by the Mahometans as incense.

Opopanax Chironium, Koch. Southern Europe, along the Mediterranean Sea. This plant is supposed to be the source of a rare and costly gum-resin known as *OPOPANAX* (see *Opopanax*).

AMMONII BENZOAS (U. S. P.)—AMMONIUM BENZOATE.

FORMULA: $\text{NH}_4\text{C}_7\text{H}_5\text{O}_2$. MOLECULAR WEIGHT, 138.72.

SYNONYMS: *Ammonia benzoas*, *Ammonium benzoicum*.

Preparation.—Mix equal amounts of ammonia water and distilled water, and dissolve in the mixture enough benzoic acid to bring to slight acid reac-

tion. Then make the solution slightly alkaline by the addition of ammonia water and evaporate to dryness, occasionally adding a few drops of ammonia water. Two parts by weight of benzoic acid require about $3\frac{1}{2}$ parts of ammonia water. Benzoate of ammonium can easily be crystallized, if the operator prefers, instead of evaporating the solution to dryness.

Description.—The following description is that of the official salt: "Thin, white, 4-sided, laminar crystals, odorless, or having a slight odor of benzoic acid, a saline, bitter, afterward slightly acrid taste, and gradually losing ammonia on exposure to the air. Soluble at 15° C. (59° F.) in 5 parts of water, and in 28 parts of alcohol; in 1.2 parts of boiling water, and in 7.6 parts of boiling alcohol. When strongly heated, the salt melts, emits vapors having the odor of ammonia and benzoic acid, and is finally completely dissipated. The salt is neutral, or has a very slightly acid reaction upon litmus paper. A saturated, aqueous solution of the salt affords, with ferric chloride T.S., a flesh-colored precipitate, and when it is gently heated with potassium or sodium hydrate T.S., the odor of ammonia is evolved. If diluted nitric acid be added to a 10 per cent aqueous solution of the salt, a precipitate of benzoic acid is produced, which, when thoroughly washed, should respond to the tests of purity mentioned under *Acidum Benzoicum*, and the filtrate from this precipitate should not be affected by barium chloride T.S. (absence of sulphate), or by silver nitrate T.S. (absence of chloride)"—(U. S. P.). This salt must be kept in well-stoppered vials.

Action, Medical Uses, and Dosage.—This salt is a mild diuretic, somewhat stimulant, forming hippuric acid with decrease of urea in the urine. It has been employed as a diuretic in cases of *deficient activity of the renal organs*, in *chronic irritation of the urinary mucous membrane*, in *phosphatic urinary sediments*, of which it tends to aid the solution, and in *gout*. Its uses are much the same as those of benzoic acid. It should be employed as indicated below. The dose is from 10 to 60 grains, in water, 2 or 3 times a day.

Specific Indications and Uses.—Scanty and pungent, dark-red urine, with thick deposits; urinary incontinence of the aged, with cystic irritation or sub-acute inflammation, and headache, drowsiness, pain in loins and limbs. A 2x trituration in doses of 2 or 3 grains is recommended for the urinary troubles of the aged.

AMMONII BROMIDUM (U. S. P.)—AMMONIUM BROMIDE.

FORMULA: NH_4Br . MOLECULAR WEIGHT: 97.77.

Preparation.—Add a solution of carbonate of ammonium to a solution of bromide of iron, stirring constantly as long as a precipitate results, and until the ammonium carbonate is in slight excess. Filter the liquid from the magma and wash the precipitate well with water, adding the washings to the original filtrate. Lastly, evaporate the mixed liquids to dryness. Bromide of ammonium may also be made by saturating hydrobromic acid with ammonia water and evaporating the product to dryness.

Description and Tests.—"Colorless, transparent, prismatic crystals, or a white, crystalline powder, odorless, of a pungent, saline taste, and permanent in the air. Soluble at 15° C. (59° F.), in 1.5 parts of water, and in 30 parts of alcohol; in 0.7 part of boiling water, and in 15 parts of boiling alcohol. When heated, the salt volatilizes completely without melting. The aqueous solution of the salt has a slightly acid reaction upon litmus paper. When the aqueous solution is gently heated with potassium or sodium hydrate T.S., the odor of ammonia is evolved. If to another portion of the solution a little chloroform be added, and subsequently a few drops of chlorine water, and the whole agitated, the chloroform will acquire a yellowish or yellowish-brown color without a violet tint. If a few drops of diluted sulphuric acid be brought in contact with a little of the powdered salt on a porcelain plate, the salt should not at once assume a yellowish color (absence of bromate). A 10 per cent aqueous solution should not be affected by hydrogen sulphide T.S. (absence of metals), nor by barium chloride T.S. (absence of sulphate). 20 Cc. of a 5 per cent

aqueous solution of the salt should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide T.S. (limit of iron). If 3 Gm. of the salt, dried at 100° C. (212° F.), be dissolved in water to the measure of 100 Cc., 10 Cc. of this solution, after the addition of a few drops of potassium chromate T.S., should require not more than 30.9 Cc. of decinormal silver nitrate V.S. to produce a permanent red coloration (absence of more than 1 per cent of ammonium chloride)"—(U. S. P.).

Action, Medical Uses, and Dosage.—According to Dr. Gibb, this salt is tonic, sedative, or antispasmodic, according to the quantity given, and the mode of administration. In large doses, frequently repeated, or given at intervals, it influences the entire mucous tract, affects all the special senses, and produces impaired sensibility of the various mucous outlets. In very large doses it produces poisonous effects analogous to those caused by similar doses of bromide of potassium. Though more irritant to the stomach, it is less depressing to the heart than the latter salt. It is more certain and reliable in small doses, causing no diarrhoea nor diuresis, while its special properties are exerted sooner, and with less inconvenience. In small doses, more or less continued, it acts as a tonic and absorbent, and exerts its peculiar properties on the skin and mucous membrane; it possesses a soothing influence on the mucous membrane, and according to the strength and mode of its application, so does it diminish the sensibility; it improves the intellectual powers, increases the bodily capacity, and promotes healthy functions; when continued with a well regulated diet, it diminishes the weight of the body, causing absorption of fat in the economy, and arresting atheromatous changes. It has been found beneficial in *corpulency, cutaneous diseases, glandular and other enlargements, scrofulous affections, scrofulous ophthalmia, and epilepsy* due to certain causes. Bromide of ammonium is serviceable in *pertussis*, in doses of 1 grain for each year of the patient's age, repeating the dose several times a day. The cases in which it is valuable are those in which the cough is associated with epileptiform movements of the extremities, or where the movements of the chest are more or less convulsive. It is also employed in cases of *nervous prostration*, from sexual excesses or masturbation, accompanied with deranged sexual nervous power. Prof. J. M. Scudder (*Dis. of Child., Spec. Med.*), preferred this to all other drugs in *epilepsy*, though he did not claim it would cure all cases. He regarded the remedy as a nerve stimulant, and used it where the symptoms pointed to enfeebled cerebral circulation, and to relieve irritation of the brain and spinal cord giving rise to convulsive disorders. The cases were those of disordered innervation, the movements being epileptiform, or partially spasmodic, with enfeebled cerebro-spinal centers. Where the tendency was to repeated convulsions from slight causes, he employed it to relieve the predisposition; and when convulsions had already occurred, and had been checked by other means, he used bromide of ammonium to prevent their recurrence. Foltz (*Dynam. Therapeutics*) uses it in *nervous deafness*, and to relieve the tinnitus from the use of cinchona alkaloids; it is also a remedy for nervous twitching and jerking of the eyelids and ocular muscles. Ammonium bromide will promote sleep when *insomnia* is due to cerebral excitement (Locke). The dose is from 1 to 30 grains (1 to 5 grains for children), well diluted with water, which may be repeated 2 or 3 times a day; it is best taken dissolved in water.

Specific Indications and Uses.—Tendency to convulsions; epileptiform disease; convulsions when there is a return to consciousness; sudden movements of the body and limbs, jerking of tendons, facial twitching, with eyes turned upward; lack of ocular accommodation. Spasmodic or convulsive cough; whooping-cough. A minor indication is, small pulse with unusual pallor of the skin, though one is not to be guided by this alone.

AMMONII CARBONAS (U. S. P.)—AMMONIUM CARBONATE.

FORMULA: $\text{NH}_4\text{HCO}_3 \cdot \text{NH}_4\text{NH}_2\text{CO}_2$. MOLECULAR WEIGHT: 156.77.

SYNONYMS: *Mild volatile alkali, Volatile salt, Sesquicarbonate of ammonia, Hartshorn, Sal volatile, Preston's salt, Smelling salt, Alkali volatile, Sal volatile siccum, Ammoniae sesquicarbonas, Carbonas ammonicus.*

Source and History.—By distilling decomposed urine, Raymond Lully was the first to prepare this salt. Afterwards it was found that it could be obtained by distilling such nitrogenous material as blood, hoof, horn, and other animal tissues (salt of hartshorn), after which it was purified with animal charcoal. Sal ammoniac and sal tartar were later employed by the monk Basil Valentine, but still later chalk was substituted for the potassium salt. The principal source of ammonium carbonate is coal-gas liquor, as described under *Ammonia*.

Preparation.—Take of finely powdered chloride of ammonium, 1 pound; carbonate of calcium (chalk), finely powdered and dried, $1\frac{1}{2}$ pounds. Mix them together thoroughly, and subject the mixture in a retort with a proper receiver to a gradually increasing heat so long as any vapors sublime—(Ed.). By this process calcium chloride is yielded, which remains in the retort, while ammonia, water, and carbonate of ammonium distill over, and the latter condenses in the cooler portions of the condenser as a white sublimate. This product is not the neutral carbonate of the composition $\text{CO}_2(\text{NH}_4)_2$, but a mixture of equal molecules of *hydrogen ammonium carbonate* (acid or bicarbonate of ammonium) and *carbamate of ammonium*. The reaction resulting from the above operation may be thus expressed: $4\text{NH}_4\text{Cl} + 2\text{CaCO}_3 = \text{NH}_4\text{HCO}_3 + \text{NH}_4\text{NH}_2\text{CO}_2 + 2\text{CaCl}_2 + \text{NH}_3 + \text{H}_2\text{O}$. Its empirical formula would be represented by $\text{N}_2\text{H}_5\text{C}_2\text{O}_3$.

Description and Tests.—Ammonium carbonate is in the form of "white, hard, translucent, striated masses, having a strongly ammoniacal odor without empyreuma, and a sharp, saline taste. On exposure to the air, the salt loses both ammonia and carbonic acid, becoming opaque, and is finally converted into friable, porous lumps, or a white powder"—(U. S. P.). The valuable constituent of this salt is its volatile portion—that which makes up the *carbamate of ammonium*—and the change above mentioned when the salt is exposed to the air, is due to the escape of this substance. The remaining light, porous, friable masses or powder, which lack the ammoniacal pungency, consist of the bicarbonate of ammonium. Hence it will be seen at once that the product should be kept in securely glass-stoppered bottles, in a cool place, and not, as is often the case, in drawers and casks, if its full therapeutic properties are to be preserved. In making such preparations as *Liquor Ammonii Acetatis*, only the translucent lumps should be employed, as they alone contain the active medicinal agent, the *ammonium carbamate*. Ammonium carbonate that has decomposed, should be discarded. This salt is sometimes found to have a slightly pinkish color, due to iron present as an impurity. When condensed in a leaden receiver, small fragments or clippings of lead may be found adherent to the surface.

Ammonium carbonate is "slowly but completely soluble in about 5 parts of water at 15°C . (59°F .); decomposed by hot water with the elimination of carbonic acid and ammonia. By prolonged boiling with water, the salt is completely dissipated. Alcohol dissolves the carbamate ($\text{NH}_4\text{NH}_2\text{CO}_2$), and leaves the acid carbonate (ammonium bicarbonate). When heated, the salt is completely volatilized, without charring. The aqueous solution possesses a strongly alkaline reaction, and effervesces with acids"—(U. S. P.). It is incompatible with acids, caustic potash, or caustic soda, magnesia, alkaline carbonates, lime-water, chloride of calcium, alum, bitartrate of potassium, bisulphate of potassium, bichloride of mercury, most salts of iron and lead, sulphate of zinc, etc. Combined with sulphate of quinine, in fluid or solid form, decomposition ensues, with the formation of sulphate of ammonium and quinine.

"A 5 per cent aqueous solution of the salt, slightly supersaturated with acetic acid, should not be affected by hydrogen sulphide T.S. (absence of metals), nor by barium chloride T.S. (sulphate), or ammonium oxalate T.S. (calcium). A 5 per cent aqueous solution, on the addition of a slight excess of silver nitrate T.S., and subsequent supersaturation with nitric acid, should neither assume a brown color (absence of hyposulphite), nor become more than slightly opalescent within 2 minutes (limit of chloride). If 1 Gm. of the salt be slightly supersaturated with nitric acid, and the solution evaporated to dryness on a water-bath, it should afford a colorless and odorless residue, which, upon gentle ignition, should be completely volatilized (absence of empyreumatic or non-volatile matters). If 7.84 Gm. of unaltered ammonium carbonate be dissolved in water to the volume of 90 Cc., 30 Cc. of this solution (containing 2.613 Gm. of the salt) should

require, for exact neutralization, 50 Cc. of normal sulphuric acid V.S. (each cubic centimeter corresponding to 2 per cent of the pure salt), rosolic acid being used as indicator"—(U. S. P.).

Action, Medical Uses, and Dosage.—Carbonate of ammonium quickly enters the blood, increasing its alkalinity, and is chiefly eliminated by the kidneys and somewhat less by the skin and lungs. The renal, cutaneous, and bronchial secretions are augmented by it, and in health it is asserted to elevate the temperature somewhat. Moderate doses (5 to 10 grains) increase the force and volume of the circulation, with sometimes a sense of constriction or throbbing in the head. In large doses it is a powerful irritating poison; in small doses it is an energetic diffusible stimulant and antispasmodic. The effects of an overdose are gastro-intestinal inflammation, pains in the abdomen, convulsions, nervous derangement, and death. When fatal doses have been swallowed, the post mortem signs are gastro-intestinal inflammation, with pulmonary congestion and oedema. Ammonium carbonate should not be administered for any great length of time, for besides neutralizing the acid of the gastric juice and producing diarrhœa and like disturbances, it destroys the blood, with symptoms resembling scurvy, and increases tissue waste in a degree to cause pallor, debility, and emaciation. The antidotes to acute poisoning by this agent are diluted acids, with demulcents and protectives to allay the after-effects.

Ammonium carbonate is stimulant, diaphoretic, and expectorant. In doses of 20 to 30 grains, it is emetic. Its stimulating properties render it useful in low continued fevers, in which it acts without increasing the circulation or the cerebral functions. In typhoid fever it may be used where alcohol would irritate. It is also useful as an antacid in gastric derangement from dissipation, epilepsy, and sick-headache. As a remedy to sober drunken individuals, it is very prompt, but less efficient than the solution of the acetate; in delirium tremens, with cerebral anemia and weak circulation, it may be used to advantage. It has also proved of great value in certain cutaneous affections, psoriasis, lepra, etc. Combined with guaiacum, it has been serviceable in chronic rheumatism, and has likewise proved beneficial in epilepsy, hysteria, chorea, scrofula, and other chronic disorders, more especially when these are attended with acidity and debility of the digestive organs. Full doses have been given to occasion vomiting in paralysis. "In broken down constitutions with greatly diminished vitality, when an antacid is needed, this is the best remedy known" (Locke's *Syllabus*, 215). Give 5 grains in sweetened water. It is especially serviceable in prostration from acute disease (Scudder, *Dis. of Child.*, 39). It is a prompt agent, both internally and locally, to relieve the distressing symptoms from insect and serpent bites. Amenorrhœa and dysmenorrhœa, of asthenic character, are benefited by it. In lung diseases, with marked enfeeblement and bronchial dilatation, it is advantageous; and in the latter stage of typhoid pneumonia, it may be given in an infusion of boneset. Here it acts as a tonic and expectorant, lessening secretion, making expectoration easier, and sustaining the strength of the patient (Locke). Following the specific indications below, it will be found valuable in many disorders, whether it be a commencing coryza, the exanthemata, or other conditions. Externally, ammonium carbonate is a gentle rubefacient, but is seldom employed as such. The dose is from 5 to 20 grains every 3 or 4 hours, in the form of a pill or dissolved in some aqueous vehicle. For its specific use, the dose preferred is from $\frac{1}{4}$ to 1 grain every hour.

Specific Indications and Uses.—Feeble pulse, imperfect surface circulation, pallid or dusky, cold skin, difficult breathing, restlessness and insomnia (from debility). As a stimulant where alcohol is inadmissible; broken-down constitution, with low vitality and acidity of the stomach; feeble heart, with aching sensations about the organ; tendency to fainting and collapse; distressing cough, with viscid, scanty and difficult expectoration, particularly in the aged.

Smelling Salts.—Formerly ammonium carbonate was much used under the name of *Smelling Salts*, combined with some aromatic oil, as a stimulant in hysteria, fainting, headache, etc. An old and popular salt may be made as follows: Take oil of cloves, 1 flʒ; oil of lavender, 2 flʒ; essence of bergamot, 5 flʒ; liquor ammoniæ, specific gravity 0.880, 1 pint. Mix, and make an essence. Fill the bottles with rough carbonate of ammonium, then add as much of the above essence as the salt will absorb.

Related Compounds.—HYDROGEN AMMONIUM CARBONATE, or *Bicarbonate of ammonium* (NH_4HCO_3), described on p. 174, is the white salt left when commercial ammonium carbonate is exposed to the atmosphere, or when the carbamate is separated from it by solution in alcohol. About 8 parts of water dissolve it. When dry it does not give off the odor of ammonia. It sometimes occurs in crystalline condition "in Patagonian guano and in the purifiers of gas-works" (Lloyd's *Chem.*). It is without value as a medicine.

AMMONIUM CARBAMATE.—This constituent of commercial ammonium carbonate is a crystalline, deliquescent powder. It has the pungent odor of ammonia gas, and when heated in a sealed tube to 140°C . (284°F .), it is decomposed, water and urea resulting. It may be prepared by bringing together dry carbon dioxide and dry ammonia gas, or by passing both gases into cold absolute alcohol. When this salt is left in aqueous solution it forms *normal ammonium carbonate*, thus: $\text{NH}_4\text{NH}_2\text{CO}_2 + \text{H}_2\text{O} = (\text{NH}_4)_2\text{CO}_3$. So that when commercial carbonate of ammonium is brought into watery solution, the latter contains some normal ammonium carbonate, and the remaining acid carbonate may be converted into the same by adding to the solution a little aqua ammoniæ. Such a solution is valuable as a reagent.

AMMONIUM EMBELLICUM ($\text{C}_6\text{H}_{15}\text{O}_2\text{NH}_4$). This ammonium salt of embelic acid is a brick-red powder, soluble in diluted alcohol. In pills of 3 (children) to 6 (adults) grains, it is reported an efficient tænicide.

AMMONIUM BORATE, *Ammonium bîborate* ($2[\text{NH}_4\text{HB}_2\text{O}_4] \cdot 3\text{H}_2\text{O}$).—Dissolve in warmed ammonia water, specific gravity 0.960 (3 parts), boric acid (1 part, in excess), and allow the solution to slowly cool. Crystals form, which are alkaline in taste and reaction, and on exposure effloresce, with a loss of ammonia, changing gradually to the tetraborate. It dissolves in water (1 in 12). Dose: From 10 to 20 grains in liquorice water every hour. Highly praised in *renal colic*, *calculus*, and *chronic vesical catarrh*.

AMMONIUM URAS, *Ammonium urate* ($\text{C}_5\text{H}_2[\text{NH}_4]\text{N}_4\text{O}_3$).—An acid compound prepared by digesting uric acid in ammonia water, or by dissolving in solutions of other urates a sufficient quantity of ammonium chloride. It is present in most grades of guano. Ammonium urate is an amorphous, white powder, not very soluble. It has been used as an ointment (20 grains to 1 ounce) in *chronic eczematous disorders*.

AMMONIUM ARSENAS, *Ammonium arsenate* ($[\text{NH}_4]_3\text{H}_3\text{AsO}_4$).—Efflorescent crystals of an alkaline salt obtained by adding a solution of ammonia, or carbonate of ammonium, to strong solution of arsenic acid, and spontaneously evaporating the same. Half the ammonia is dissipated upon exposure to air. From 20 to 25 drops (in divided doses throughout the day) of a solution of 1 grain of ammonium arsenate in 1 fluid ounce of pure water, has been lauded in *stubborn skin affections*.

AMMONIUM SALICYLATE, *Salicylate of ammonium*.—This agent may be prepared extemporaneously in neutral solution as follows: R Acid salicylic, ʒij; ammonium carbonate, grs. cxi; aqua menthæ piperitæ, flʒiv. Mix. The dose of this preparation is from 1 to 2 fluid drachms every 2 hours. This drug comes highly recommended as an abortive of *typhoid* and *remittent* and allied fevers. It is classified as antiseptic, germicide, antipyretic, stimulant, and analgesic. Several observers declare it the best salt of salicylic acid. It is claimed that it will generally abort the above-named fevers, and should it fail to do so it will render their course much milder. It readily reduces temperature and holds it down. It modifies or checks the intestinal discharges, and yet when *constipation* is present, is said to operate as a laxative. The *headache* of these fevers is said to be promptly controlled, and sleep is favored by it. The skin and kidneys become more active under its use, and the urine assumes a paler hue, and if offensive, is partially deodorized. Prof. Webster (*Dynam. Ther.*, 53) reports success with it. It deserves investigation.

GUANO.—This valuable fertilizer is composed of the wholly or partially decomposed excrements of various sea-birds, notably the penguin, inhabiting the western shores of South America, and the coasts of Australia and Western Africa. The bulk of the commercial guano comes from the islands of the Pacific opposite Bolivia and Peru (Galapagos Islands). Guano usually comes in the form of grayish or light-brown powder, intermixed with friable lumps. It may be amorphous or crystalline. It is hygroscopic, absorbing from 6 to 20 per cent of moisture, becoming "tacky." Its odor is very offensive, somewhat ammoniacal. Though sometimes of acid reaction, guano is usually alkaline. Besides moisture, it contains organic matter and salts of ammonium, notably ammonium oxalate and carbonate, tricalcic phosphate, and other alkaline salts, uric acid, and salts of the same, phosphates, sulphates, and chlorides of calcium, magnesium, etc. Guano is largely soluble in water. An alkaloidal substance, *guanine* ($\text{C}_5\text{H}_7\text{N}_5\text{O}$), was found in it by Unger, in 1845. Nitrous acid, acting upon guanine, produces *xanthine* ($\text{C}_5\text{H}_4\text{N}_4\text{O}_2$), and this in turn has been converted into *caffeine* and *theobromine* (Fischer). *Guanine* is a constituent of pancreatic juice, and occurs as a crystalline, white powder, soluble in solution of caustic potash and acid media, but not in water, ammonia, alcohol, or ether. When burned, guano leaves from 25 to 40 per cent of a white ash. This disgusting substance has been administered internally in the form of a syrup, and was at one time applied topically, mixed with potter's clay, in various cutaneous disorders. Its irritating properties led to its abandonment as a medicinal agent. Its only use at present is as a fertilizer.

AMMONIUM MOLYBDAS, *Ammonium molybdate* ($[\text{NH}_4]_3\text{MoO}_4$).—This is a salt of molybdic acid (H_2MoO_4) and ammonium, and may be prepared by dissolving molybdenum trioxide (MoO_3) in aqua ammoniæ, and, by means of alcohol, precipitating the salt so formed. It is a valuable test reagent for the detection of alkaloids and of phosphoric acid. When ammonium molybdate, in the presence of nitric acid, is added to phosphoric acid or a solution of a phosphate, *ammonium phosphomolybdate* ($11[\text{MoO}_3] \cdot [\text{NH}_4]_3\text{PO}_4 \cdot 6\text{H}_2\text{O}$), is formed.

AMMONII CHLORIDUM (U. S. P.)—AMMONIUM CHLORIDE.**FORMULA:** NH_4Cl . **MOLECULAR WEIGHT:** 53.38.**SYNONYMS:** *Hydrochlorate of ammonium, Muriate of ammonia, Chlorhydrate of ammonia, Sal ammoniac, Purified ammonium chloride, Sal ammoniacum, Ammoniae hydrochloras, Ammoniae murias, Chloruretum ammonicum, Ammonium hydrochloratum depuratum, Ammonium muriaticum depuratum.***Source, History, and Preparation.**—Chloride of ammonium is found native, especially in the neighborhood of volcanoes, and in the waters of some mineral springs. It was first prepared in Egypt from the soot of camel dung by sublimation. Geber obtained sal ammoniacum from urine. At present it is prepared in various ways, for instance, by the union of dry hydrochloric acid gas and dry ammoniacal gas; or by the double decomposition of sulphate of ammonium and chloride of sodium. The sulphate of ammonium is obtained principally from gas-liquor, as described under *Ammonii Sulphas*. In order to obtain ammonium chloride from the ammoniacal gas-liquor direct, the latter is distilled with lime, and the ammonia thus formed is conducted into diluted hydrochloric acid. The solution, when sufficiently strong, is evaporated to dryness and the sal ammoniac purified by sublimation.**Description.**—Ammonium chloride is usually sold in thick cakes, convex on one surface, concave on the other, colorless, translucent, tough, fibrous, permanent in the air if dry, but becoming slightly moist and unctuous to the touch if exposed to dampness; no odor, but possessing a pungent, saline, acrid taste. The salt is sometimes tinged or streaked with red, due to iron. It is an anhydrous salt of the composition NH_4Cl . Its specific gravity is 1.520. When dissolved in water, cold is produced during the solution. It is not readily reduced to powder, but this may be accomplished by making a strong aqueous solution, heating it to 100°C . (212°F .), stirring it constantly until it is cold; by this process granulation of the salt takes place, and after thoroughly drying it, it may be easily pulverized. It is decomposed by sulphuric and nitric acids; also by hydroxides of potassium, sodium, barium, and calcium. The official salt is thus described: "A white, crystalline powder, without odor, having a cooling, saline taste, and permanent in the air. Soluble in 3 parts of water at 15°C . (59°F .), and in 1 part of boiling water, but almost insoluble in alcohol. On ignition, the salt is completely volatilized, without charring. The aqueous solution of the salt is neutral to litmus paper, and affords with silver nitrate T.S. a white curdy precipitate, which is soluble in ammonia water. Another portion of the aqueous solution, when gently heated with potassium or sodium hydrate T.S., evolves the odor of ammonia. A 5 per cent aqueous solution of the salt should not be affected by hydrogen sulphide T.S. (absence of metals), barium chloride T.S. (sulphate), diluted sulphuric acid (barium), or ammonium oxalate T.S. (calcium). When acidulated with hydrochloric acid, the solution should not assume a red color on the addition of a few drops of ferric chloride T.S. (absence of sulphocyanate). 20 Cc. of a 5 per cent aqueous solution of the salt should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide T.S. (limit of iron). If to 1 Gm. of the salt a little nitric acid be added, and the mixture evaporated to dryness in a porcelain capsule on a water-bath, a white residue should be obtained which, when more strongly heated, should be completely volatilized (absence of empyreumatic or non-volatile matters)"—(U. S. P.).**Action, Medical Uses, and Dosage.**—Chloride of ammonium, according to its mode of employment, is refrigerant, laxative, expectorant, diaphoretic, or diuretic. "It acts primarily on the intestinal canal, as an irritating stimulus" (Ed.). Its action upon the general system is to promote secretion and exhalation generally, soften and break down textures, check phlegmonous inflammation, lessen inflammatory effusions, and promote their re-absorption. It is said to act upon all the tissues of the system, producing the solvent effects accorded to mercurials, but without their injurious consequences. If long employed, it may occasion gastro-intestinal disturbances, with coated tongue, anorexia, difficult digestion, pain, vomiting, diarrhoea and loss of flesh. It has a tendency to produce hemor-

rhages, as epistaxis, hematuria, etc. In very large doses, it acts as a decided irritant, producing inflammation of the alimentary canal, and also coma and tetanic convulsions. In *mucous diseases of the throat, nasal passages, and Eustachian pavilion*, it has been beneficially employed in the form of spray, of from 5 to 125 grains of the salt to an ounce of water; or the impalpable powder may be used in the form of powder-spray, alone, or in combination with powdered extract of liquorice, etc. The vapor of chloride of ammonium passed into the inner ear, through the Eustachian tube, by means of an instrument for this purpose, has effected cures of *chronic mucous diseases* of these parts. As an external application, it is used in the form of plaster or lotion, as a stimulating discutient, and has been found valuable in *chilblains*, "*indolent tumors of all kinds, contusions, gangrene, psora, ophthalmia, sore throat, and in stimulating clysters*;" and it is also very beneficial in *hemicrania* and other *neuralgic affections*, in which it may also be given in doses of a tablespoonful every hour, of a solution of 2 drachms dissolved in 6 fluid ounces of water, and continued until relieved. When first applied, in solution, the coldness will diminish the sense of heat and uneasiness of the part, and the subsequent stimulus will excite a more healthy action in the vessels. For these purposes a favorite lotion with some physicians is a mixture of 2 drachms of chloride of ammonium dissolved in 1 fluid ounce of distilled water, to which 1 fluid ounce of tincture of conium is subsequently added. In *erysipelas* and *erysipelatos inflammations*, I have found the following mixture an excellent local application: Take of chloride of ammonium 1 ounce, distilled water $\frac{1}{2}$ pint; mix and dissolve, then add tincture of camphor 4 ounces, tincture of lobelia 4 ounces. To be shaken each time previous to bathing with it. It allays the burning heat and itching, and in many instances assists in preventing the further development or extension of the disease (King). As a gargle or in spray, it is often serviceable in the chronic form of *tonsillitis*; use a solution of 1 or 2 drachms of the salt to about 2 or 2 $\frac{1}{2}$ fluid ounces of water, and 4 fluid drachms of alcohol. In *fluor albus* and *gonorrhœa* (as well as for a wash in *scabies* and *ulcers*), from 1 drachm to $\frac{1}{2}$ ounce may be dissolved in 12 or 16 fluid ounces of water, and used as an injection. A solution (\mathfrak{ss} in aqua $\mathfrak{f}\mathfrak{z}$ vii), is declared by Foltz to be the best agent for *palpebral ecchymosis*, and if applied early, prevents the discoloration (*Dynam. Therap.*).

Internally, ammonium chloride has been recommended in all *tuberculous diseases*, in *chronic pulmonary affections*, *rheumatic face-ache*, *hemicrania*, *ischuria*, *chronic enlargement of the prostate*, *chronic rheumatism*, *chronic bronchitis*, *neuralgia*, *nervous headache*, *chronic dysentery*, *amenorrhœa*, the result of deficient uterine action, and in all chronic diseases of mucous or serous tissues. In these cases we will be largely guided by the indications pointed out by Prof. Scudder—cases showing feeble capillary circulation, with dusky redness of the skin (not due to blood poisoning), the effacement of which is again slowly replaced by a return of the dark color. The drug is a capillary stimulant, and as such is frequently of benefit in the *exanthemata*, to favor the eruptive process. In *broncho-pulmonary disorders*, it is a valuable remedy. It is a remedy for dryness and tightness in the throat, with sharp, violent cough. *Throat disorders*, especially when chronic, with a tight, rasping cough, precipitated by a titillating or tickling in the larynx, is promptly relieved by the following: R Ammonium chloride, $\mathfrak{z}\mathfrak{i}$; sanguinaria nitrate, gr. j; spts. lavender compound, $\mathfrak{f}\mathfrak{z}\mathfrak{i}$; syrup, q. s. $\mathfrak{f}\mathfrak{z}\mathfrak{i}\mathfrak{v}$. Mix. Filter through cotton. Dose, 1 teaspoonful every 3 hours. It is also useful early in *bronchitis*, and the active stage of *catarrhal pneumonia* (1 to 3 grains every 2 or 3 hours). *Cough*, associated with sluggish abdominal circulation and hepatic torpor, and subdued cough with scanty secretion, are met by ammonium chloride in small doses. It is asserted to relieve *hepatic neuralgia*—*heptalgia*—and to be of value in *chronic catarrhal disorders of the intestinal tract*. The pain attending *biliary catarrh* is also said to be controlled by it. Dose: From 5 grains to $\frac{1}{2}$ drachm is the dose, which may be repeated 3 or 4 times a day; it may be given in the form of a powder, mixed with powdered gum or sugar, or dissolved with syrup, mucilage, extract of liquorice, etc. In large doses it purges, but in small doses it rather constipates the bowels. It may be given for a long time without any inconvenience, but at last it impairs the digestive powers.

Specific Indications and Uses.—Dusky or dull redness (non-septic) of sur-

face, easily effaced but slowly returning; cough, subdued, tight, rasping or tickling, with scanty secretion; cough dependent on hepatic torpor and imperfect abdominal circulation. Locally to ecchymosis of the lids; also as a bath in capillary enfeeblement.

AMMONII IODIDUM (U. S. P.)—AMMONIUM IODIDE.

FORMULA: NH_4I . MOLECULAR WEIGHT: 144.54.

SYNONYMS: *Ioduretum ammonicum*, *Ammonium iodatum*.

Preparation.—Place iodine, a sufficient quantity, into a dish, and add to it enough water to cover it, then add sulphide of ammonium, agitating from time to time, and continue the addition of the sulphide until the red color has disappeared; boil, to drive off the excess of the sulphide, filter, and evaporate to dryness. This process yields a salt to which traces of sulphur obstinately adhere, and even when excluded from light, discoloration is liable to occur, with evolution of free iodine. A formula has, therefore, been proposed by Mr. Jas. F. Baßcock, which produces a salt absolutely pure, and which, if carefully dried, is said to remain white for a considerable period. The process consists in the double decomposition of pure iodide of potassium and pure sulphate of ammonium, forming iodide of ammonium and sulphate of potassium; it is as follows: Dissolve by heat, iodide of potassium, 5 parts by weight, and sulphate of ammonium, 2 parts by weight, in distilled water, 4 parts by weight. On cooling, a large proportion of sulphate of potassium is deposited; and when the fluid is at 15.5°C . (60°F .), alcohol (95 per cent), 1 part by weight, is mixed with it, which separates all but about 1 per cent of sulphate of potassium, and the concentrated solution of iodide of ammonium, after evaporation, yields crystals of perfectly white iodide. Subsequent addition of alcohol will separate the whole of the sulphate of potassium from the mother liquor, which, on evaporation to dryness, will yield an additional quantity of the iodide. To give the best results, the evaporation should be performed in the dark, or in the evening by gas-light. The solution being very concentrated, will require but comparatively little boiling, and the precipitate of sulphate of potassium being crystalline, can be readily separated by filtration (*Proceedings Amer. Pharm. Assoc.*, 1866, p. 245).

This salt may also be produced directly by combining iodine with ammonia water. This mixture, however, should be prepared with the greatest of caution, as nitrogen iodide, an extremely dangerous explosive compound, is formed simultaneously with the ammonium iodide. In this way the so-called colorless tincture of iodine is prepared. The simplest and safest way of obtaining ammonium iodide is to neutralize hydriodic acid (IH) with aqua ammoniæ, and evaporate to dryness. This process is 50 per cent more expensive than by the older method (Lambert). Another process consists in preparing ferrous iodide, precipitating the iron with aqua ammoniæ, and evaporating the filtrate to dryness. Another process was introduced by Rother (*Amer. Jour. Pharm.*, 1887), consisting in the double decomposition of calcium iodide with ammonium bicarbonate.

Description and Tests.—Iodide of ammonium occurs as "minute, colorless, cubical crystals, or a white, granular powder, without odor when colorless, but emitting a slight odor of iodine when colored, and having a sharp, saline taste. The salt is very hygroscopic, and soon becomes yellow or yellowish-brown on exposure to the air and light, owing to the loss of ammonia and the elimination of iodine. Soluble at 15°C . (59°F .), in 1 part of water, and in 9 parts of alcohol; in 0.5 part of boiling water, and in 3.7 parts of boiling alcohol. When heated on platinum foil it evolves vapor of iodine, and volatilizes completely without melting. The aqueous solution of the salt is neutral to litmus paper, and, when gently heated with potassium or sodium hydrate T.S., evolves the odor of ammonia. If a little chloroform be added to 10 Cc. of the aqueous solution, then a few drops of chlorine water, and the whole agitated, the chloroform will acquire a violet color. A solution of 1 Gm. of the salt in 20 Cc. of water, acidulated with a few drops of diluted hydrochloric acid, should not afford an immediate cloudiness or precipitate with 5 drops of barium chloride T.S. (limit of sulphate). A 1 per cent aqueous solution of the salt should not at once

assume a blue color with potassium ferrocyanide T.S. (limit of iron), nor, after being mixed with a little starch T.S., should it assume a deep-blue color (limit of free iodine). If 0.25 Gm. of the salt be dissolved in 10 Cc. of ammonia water, the solution then shaken with 19 Cc. of decinormal silver nitrate V.S., and the filtrate supersaturated with 5 Cc. of nitric acid, no cloudiness should make its appearance within 10 minutes (absence of more than about 0.5 per cent of chloride or bromide)"—(U. S. P.). "Ammonium iodide should be kept in small, well-stoppered vials, protected from light. When deeply colored, the salt should not be dispensed, but it may be deprived of free iodine by adding to its concentrated aqueous solution, sufficient ammonium sulphide T.S. to render it colorless, then filtering, and evaporating on a water-bath to dryness"—(U. S. P.). The coloring of the salt red by the liberation of free iodine, may be overcome by triturating the salt with a few drops of hypophosphorous acid, which combines with the iodine to form a product which does no harm, and at the same time the salt is freed from the irritating qualities it may possess when free iodine is present.

Action, Medical Uses, and Dosage.—The action of ammonium iodide is somewhat analogous to that of iodide of potassium, its therapeutic effects being, however, more rapidly evidenced. It frequently produces diuresis, and also appears to have a well-marked and satisfactory influence in the reduction of glandular swellings. It has been very successfully employed in *scrofula*, *constitutional syphilis*, *glandular enlargements*, *chronic rheumatism*, *phthisis pulmonalis*, and in *strumous disorders* generally. It is of great value in the localized headache of *syphilis*, and is indicated in dull headache from strumous disorders and other causes, with feeble, sluggish circulation, dizziness, unsteady gait, and difficulty in controlling voluntary movements. The pain seems confined to a small area, as in inflammation, which may be covered with the finger tip. In *pericranial headache*, with cerebral excitement, it is also a good remedy. In *secondary syphilis*, it gives good results where the "tissues give the pinched and stringy sensation to the touch" (Scudder, *Spec. Diag.*, 144). Foltz values it in *syphilitic eye disease*, with depression, giving 2 grains every 2 hours; also in *syphilitic disease of the internal and middle ear*, particularly in *suppurative otitis media*, he considers it one of the most useful of agents (*Dynam. Therap.*). The dose for an adult is from 1 to 3 grains, repeated 3 or 4 times a day; it may be taken dissolved in water. A liniment made by dissolving $\frac{1}{2}$ drachm of the iodide in 1 ounce of glycerin, and applied to *enlarged tonsils* by means of a camel's-hair brush, once or twice a day, has, in the course of three or four months, aided by internal use of the salt, effected their complete and permanent reduction. The same liniment employed in frictions, has been found beneficial in *nocturnal syphilitic pains* of the muscles or joints. An ointment (20 or 30 grains to 1 ounce of lard) has been efficacious in *lepra* and *psoriasis*, and in what is known as "*camp or prairie itch*," applying about $\frac{1}{2}$ ounce of it in frictions, twice a day. But a small quantity of this ointment should be prepared at a time, and kept in well-stoppered vessels, as the action of the air decomposes the iodide.

Specific Indications and Uses.—Localized pain in the head; dull pain in the head, with tinnitus aurium; vertigo; unsteady gait, and difficulty in controlling muscular movements; circulation feeble and sluggish; pericranial headache, with cerebral excitement; secondary syphilis, with stringy, pinched tissues; syphilitic diseases of the eye and ear, with depression.

AMMONII NITRAS (U. S. P.)—AMMONIUM NITRATE.

FORMULA: NH_4NO_3 . MOLECULAR WEIGHT: 79.9.

SYNONYMS: *Ammonium nitricum*, *Nitrum flammans*, *Ammoniae nitras*, *Nitrate of ammonia*.

Preparation and History.—Nitrate of ammonium (discovered by Glauber) has been known for a great many years, and was formerly termed *nitrum flammans*. It is readily prepared by adding ammonia, or ammonium carbonate, to diluted nitric acid, until the mixture becomes neutral, and then evaporating it slowly to crystallization. As found in the market, for the purpose of making nitrogen monoxide, it is in the form of a white, fibrous mass, in which case it is

prepared by quick boiling until a portion will become solid when placed upon a cold porcelain slab. The mass is then allowed to cool, broken into fragments, and preserved in a cool place. As thus prepared it is known by the name *fused nitrate of ammonium*. This salt was of little interest until the introduction of nitrous oxide, when a demand for it was created. When ammonium nitrate and manganese dioxide in equal amounts are heated together, at the temperature of from 182° to 204° C. (360° to 400° F.), pure nitrogen is evolved, but above 212° C. (420° F.), teroxide of nitrogen and oxygen accompany (*Chem. News*, Vol. XXXV). Dry ammoniacal gas is absorbed in large amount when passed over ammonium nitrate, attended by liquefaction of the salt. At 0° C. (32° F.), half the weight of the salt will be condensed (*Phil. Trans.*, 1873). When quickly raised to a high temperature, dry nitrate of ammonium decomposes into nitrogen, water, and nitric oxide, whereas, when gently heated, in an apparatus, as illustrated below, it forms water, and *nitrogen monoxide* (N_2O), or nitrous oxide.

Fig. 17.

Description and Tests.—This salt is thus described in the *U. S. P.*: “Colorless crystals, generally in the form of long, thin, rhombic prisms, or in fused masses, without odor, having a sharp, bitter taste, and somewhat deliquescent. Soluble at 15° C. (59° F.), in 0.5 part of water, and in 20 parts of alcohol; very soluble in boiling water, and in 3 parts of boiling alcohol. When gradually heated, it melts at 165° to 166° C. (329° to 330.8° F.); at a temperature between 230° C. (446° F.) and 250° C. (482° F.) it is decomposed into nitrogen monoxide gas and water, leaving no residue. The aqueous solution of the salt is neutral to litmus paper, and when gently heated with potassium or sodium hydrate T.S., it evolves the odor of ammonia. On heating the salt with sulphuric acid, it emits nitrous vapors. A 10 per cent aqueous solution of the salt, when acidulated with nitric acid, should not be affected by silver nitrate T.S. (absence of chloride), nor by barium chloride T.S. (absence of sulphate)”—(*U. S. P.*). This salt should be kept closely stoppered.

Action, Medical Uses, and Dosage.—Ammonium nitrate is employed principally in the preparation of nitrous oxide, or “laughing gas.” It has rarely been employed therapeutically. Dr. Walter Coles (*Am. Med. Times*, November, 1860, p. 311) has advised its use as a tonic, and for the purpose of introducing an increased quantity of oxygen into the system. It certainly has been found beneficial in cases of *excessive debility* from *suppurating abscesses* or *ulcers*, where the mucous tissues present a dark appearance, and has, apparently, been of service in several *diabetic patients*. The dose is from 5 to 15 grains, repeated 2 or 3 times a day.

AMMONII PHOSPHAS.—AMMONIUM PHOSPHATE.

FORMULA: $(NH_4)_2HPO_4$. MOLECULAR WEIGHT: 131.82.

SYNONYMS: *Phosphate of ammonia*, *Diammonium orthophosphate*, *Phosphas ammonicus*, *Ammonium phosphoricum*, *Ammoniaz phosphas*.

Preparation.—Pour syrupy phosphoric acid gradually into ammonia water until of slight acid reaction, then add ammonia water until it is slightly alkaline. Evaporate the solution to crystallization and dry the crystals by exposure to cool air.

Description.—Phosphate of ammonium forms large, transparent crystals, odorless, of a cooling, decidedly saline taste, insoluble in alcohol, and soluble in about twice its weight of water. In damp air it slightly effloresces through loss of ammonia, and when heated with hydroxides of sodium or potassium evolves ammonia. Normal ammonium phosphate occurs in guano.

Action, Medical Uses, and Dosage.—This salt was recommended in 1846, by Dr. T. H. Buckler, for the cure of *gout* and *rheumatism*, and though the grounds upon which he commended its use are not tenable, yet the article has been found useful in these affections, and in some diseases of the urinary apparatus. The dose varies from 10 to 40 grains in $\frac{1}{2}$ fluid ounce of water, and repeated 2 or 3 times a day.

Related Salt.—AMMONII SODII PHOSPHAS, *Ammonium sodium phosphate, Microcosmic salt.* Formula: $(\text{NH}_4)\text{NaHPO}_4 + 4\text{H}_2\text{O}$. This salt has been obtained by the alchemists from evaporated urine; hence the name, microcosmic salt, implying man, or microcosm, being contrasted with the world at large, or macrocosm. It is obtained by crystallizing a mixture of 5 parts of sodium phosphate (Na_2HPO_4) and 2 parts of mono-ammonium phosphate ($\text{H}_2\text{NH}_4\text{PO}_4$). Microcosmic salt occurs in transparent, monoclinic prisms, easily soluble in water. To the taste it is distinctly saline. When heated in the loop of a platinum wire, in a Bunsen burner, it first loses ammonia and water, leaving a residue of dihydrogen sodium phosphate, and when further heated, forms a clear, glass-like bead of sodium hexa-meta-phosphate, which dissolves certain metallic salts with characteristic colors, hence its application in blow-pipe analysis. Microcosmic salt occurs also in guano.

AMMONII PICRAS.—AMMONIUM PICRATE.

FORMULA: $\text{NH}_4\text{C}_6\text{H}_3(\text{NO}_2)_3\text{O}$. MOLECULAR WEIGHT: 245.58.

SYNONYMS: *Picrate of ammonium, Carbazotate of ammonium.*

Preparation.—Add 1 part of picric acid to 8 parts of distilled water, and bring the mixture to the boiling point. Then, with constant stirring, add aqua ammoniæ until in slight excess, and filter through paper while hot. Mix the filtrate with 8 parts of alcohol, and, when cool, strain, and dry the precipitate on blotting paper, by exposure to the atmosphere.

The picric acid unites with ammonia in the foregoing operation, forming a dark orange-colored solution (picric acid dissolves with lemon-yellow color), from which the mechanical impurities are separated by filtration through paper. Owing to the fact that picrate of ammonium is almost insoluble in alcohol, and is soluble to a considerable extent in water, the alcohol is added, thus precipitating a larger amount than could be obtained by crystallization. Another advantage derived from the use of alcohol, results from the fact that a common impurity in commercial picric acid is a resinous substance produced by the action upon carbolic acid of the acids employed in making the picric acid. This resin is held in solution by the alcohol, but precipitates with the picric acid if water only is used.

Description.—Picrate of ammonium, obtained by the preceding formula, is in the form of minute lemon or orange-colored acicular crystals. It is intensely bitter, and imparts, in solution, a permanent yellow color to organic bodies, more particularly such as horn, the finger-nails, hair, etc. Solution of picrate of ammonium precipitates most of the solutions of alkaloidal salts, forming insoluble picrates of the alkaloids.

Action, Medical Uses, and Dosage.—Administered for some time to certain animals, it has occasioned a yellow discoloration of the conjunctiva, as well as of the urine; also diarrhœa, leanness, flatulency, spasmodic twitchings, etc.; and the globules of the blood, both the red and the white, become seriously changed in their character. With man, somewhat similar effects have been observed.

At one time this agent was highly extolled as an effective remedy for *intermittent fever*, and was also suggested for the destruction of *trichina* in man, but no positive or satisfactory results have been derived from its employment in these cases. Its chief use at the present day is in the preparation of colors for staining in histological investigations. The dose is $\frac{1}{2}$ to $\frac{1}{4}$ grain. On account of its intense bitterness, it should be administered in pill or capsule.

AMMONII SULPHAS.—AMMONIUM SULPHATE.

FORMULA: $(\text{NH}_4)_2\text{SO}_4$. **MOLECULAR WEIGHT:** 131.84.

SYNONYMS: *Sulphas ammonicus, Ammonium sulphuricum, Sulphate of ammonia, Sal ammonium secretum Glauberi.*

Source, History, and Description.—This salt was discovered by Libavius (Roscoe and S.), but was first investigated carefully by Glauber. It is mentioned in the early works on chemistry as *ammoniacal vitriol, vitriolic sal ammoniac*, and *Glauber's secreta sal ammoniac*. It is found in certain volcanic districts, but is made in immense amounts from ammoniacal gas-liquor, from which the ammonia is liberated by lime, and then conducted into diluted sulphuric acid; after which this solution of impure sulphate of ammonium is strained and evaporated until the salt separates. The impure brown mass formed is then recrystallized. Sulphate of ammonium occurs in long, transparent, 6-sided crystals, which are isomorphous with potassium sulphate, and have a strongly saline taste. They dissolve in their own weight of boiling, and in 2 parts of cold water; insoluble in alcohol of less specific gravity than 0.850. Sulphate of ammonium is made in large amounts in this country, and is mostly consumed in the preparation of ammonium alum, aqua ammonise, and chloride of ammonium. It also enters into the composition of ammonio-ferric alum, and is used to make other preparations of ammonium, such as iodide of ammonium, and as a fertilizer.

Medical Uses.—Sulphate of ammonium has not been employed as a therapeutical agent.

AMMONII VALERIANAS (U. S. P.)—AMMONIUM VALERIANATE.

FORMULA: $\text{NH}_4\text{C}_4\text{H}_7\text{O}_2$. **MOLECULAR WEIGHT:** 118.78.

SYNONYMS: *Ammonium valerate, Valerianus ammonicus.*

Preparation.—Pass ammonia gas into valerianic acid until the acid is saturated. Evaporate the solution to solidification and dissolve the mass in hot alcohol, from which the valerianate of ammonium separates on cooling.

Description.—Owing to its unstable qualities, this salt should be kept in well-stoppered containers. The official salt should correspond to the following description: "Colorless, or white, quadrangular plates, emitting the odor of valerianic acid, of a sharp and sweetish taste, and deliquescent in moist air. Very soluble in water and in alcohol; also soluble in ether. When heated, the salt fuses, gives off vapor of ammonia and of valerianic acid, and is finally completely volatilized. The aqueous solution has an acid reaction, and, when gently heated with potassium or sodium hydrate T.S., it evolves the odor of ammonia. If a concentrated, aqueous solution of the salt be slightly supersaturated with sulphuric acid, an oily layer of valerianic acid will separate on the surface. A 5 per cent aqueous solution, when acidulated with nitric acid, should not be affected by barium nitrate T.S. (absence of sulphate), nor by silver nitrate T.S. (absence of chloride). If a neutral solution of the salt be completely precipitated with ferric chloride T.S., the filtrate should not possess a deep-red color (absence of acetate)" —(U. S. P.). R. Rother, in 1884, proposed to substitute for ammonium valerianate an evaporated mixture of this salt with ammonia and borax, in order to overcome the objectionable odor (*Amer. Jour. Pharm.*, 1884, p. 313).

Action, Medical Uses, and Dosage.—Small doses stimulate, and large doses of ammonium valerianate depress the functions of the spinal cord (Parke). This salt has been highly recommended in *neuralgia, epilepsy, headache, nervous irritability, chorea*, etc. The dose of the salt is from 4 to 10 grains 3 times a day; of *Decolat's solution* (containing $\frac{1}{4}$ part by weight of the salt), from 1 fluid drachm to $\frac{1}{2}$ fluid ounce, according to the urgency of the symptoms. For *epilepsy*, or other fully developed *convulsive disorders*, however, it is of no value whatever. *Elixir of Valerianate of Ammonium* is a preparation designed to disguise the disagreeable taste of the valerianate, and for which several formulæ have been proposed. One, about as useful as any, is as follows: Take, of valerianate of ammonium, 1 drachm; fluid extract of vanilla, $\frac{1}{2}$ fluid ounce; compound tincture of

cardamom, 4 fluid drachms; tincture of prickly ash berries, 2 fluid drachms; syrup of orange flower, 6 fluid drachms; water, $3\frac{1}{2}$ fluid ounces. Mix. The dose is a teaspoonful, to be repeated 3 times a day.

AMPELOPSIS.—AMERICAN IVY.

The bark and young twigs, with leaves, of the *Ampelopsis quinquefolia*, Michaux (*Vitis hederacea*, Willdenow; *Cissus quinquefolia*, Persoon; *Vitis quinquefolia*, Moench; *Cissus hederacea*, Barton).

Nat. Ord.—Ampelidaceæ.

COMMON NAMES: American ivy, Virginian creeper, Five leaves, Woodbine, False grape, Wild wood vine.

Botanical Source.—This is a woody vine, with a rooting, climbing stem, and quinate and digitate leaves composed of oblong, acuminate, petiolate, dentate, smooth leaflets which turn crimson in autumn. The flowers are inconspicuous, greenish or white, and borne in dichotomous clusters; calyx entire; petals 5, distinct and spreading; ovary 2-celled, cells 2-ovuled; style very short; berries dark-blue, acid, smaller than peas, 2-celled, cells 1 or 2-seeded.

Fig. 18.

A. quinquefolia.

History.—The American ivy is a common and familiar shrubby vine, climbing extensively, and, by means of its radicating tendrils, supporting itself firmly upon trees, ascending to the height of 50 feet; in the same manner it ascends and overspreads walls and buildings; its large leaves constituting a luxuriant foliage of dark glossy-green. It is found in wild woods and thickets throughout the United States, and blossoms in July, ripening its small blackish berries in October. The bark and twigs are the parts used. Its taste is acrid and persistent, though not unpleasant, and its decoction is mucilaginous. The bark should be collected late in the fall, after the berries have ripened. Bernays (*P. J. Tr.*, Vol. VII, p. 80) reports poisoning by the leaves, with severe emesis, diarrhœa, collapse, and narcosis, with dilatation of the pupils. This plant is frequently thought to be poison vine (*Rhus Toxicodendron*). It differs from the latter, however, among other ways, in having 5 instead of 3 leaflets, so that any one may easily differentiate the two vines. It may be handled with impunity. [Compare with illustration of *Rhus Toxicodendron*]. *Ampelopsis*, one of the old "resinoids or concentrations," is unworthy of consideration as a medicine.

Chemical Composition.—Analysis shows that the leaves and berries have the same constituents, differing only in the latter not containing *glycolic acid*. Analysis of the leaves gathered in midsummer, revealed albumen, pyrocatechin, sugar, tartaric acid (free), bitartrate of potassium, and tartrate of calcium, while neither free tartaric acid nor bitartrate of potassium were found in the leaves collected in early autumn (September), but two additional substances, pectin and calcium glycolate, were detected. The analyses were made by Wittstein and Gorup-Besanez.

Action, Medical Uses, and Dosage.—Alterative, tonic, astringent, and expectorant. Used principally in the form of syrup in *scrofula*, *syphilitic affections*, and wherever an alterative is required. It has also been recommended in *dropsy*, *bronchitis*, and other *pulmonary complaints*. Dose of the syrup or decoction, 2 to 4 fluid ounces, 3 times a day; tincture, 10 to 30 drops, 3 times a day.

Specific Indications and Uses.—In faulty nutrition, and scrofulous diathesis, with sluggish lymphatic action.

Related Species.—*Ampelopsis Botrya*, De Candolle. Habitat, southeast Africa. Diuretic. Root employed.

AMYGDALA.—ALMOND.

I. AMYGDALA AMARA (U. S. P.)—Bitter almond. "The seed of *Prunus Amygdalus*, var. *Amara*, De Candolle" (U. S. P.). (*Amygdalus communis*, var. *Amara*).

II. *AMYGDALA DULCIS* (U. S. P.)—*Sweet almond*. "The seed of *Prunus Amygdalus*, var. *Dulcis*, De Candolle" (U. S. P.). (*Amygdalus communis*, var. *Dulcis*).

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 99.

Botanical Source.—The *Prunus Amygdalus*, or Almond tree, is from 10 to 18 feet high, with a pale-brown, rugged bark, and dividing into many spreading branches. The leaves, which are borne on glandular petioles, are between 2 and 4 inches long, about 9 lines broad, lanceolate, acuminate, thin, serrated, bright light-green, and glandular near the base. The flowers are moderately large, pink or white, sessile, and in pairs, appearing before the leaves. The calyx is reddish, with blunt segments. The petals are variable in size, always much larger than the calyx, ovate, concave, and irregularly notched. Stamens spreading, about half the length of the petals. The ovary is woolly; the style simple. The fruit a leathery, hoary drupe, with the sarcocarp spontaneously cracking and dropping off the putamen. The stone is oblong, or ovate, acute, hard in various degrees, always rugged, and pitted with irregular holes. The seed is oblong, compressed, ovate, with brown testa, at the apex of which there is a broad, round, brown chalaza. The cotyledons are very large, and plano-convex. Both the sweet and bitter almonds are taken from this tree, of which there are several varieties—the sweet almond is obtained from the var. *Dulcis*, and the bitter almond from the var. *Amara* (L.).

Fig. 19.
Prunus Amygdalus.

History.—The Almond tree is indigenous to most of the southern parts of Asia and Barbary, and is cultivated in many parts of Southern Europe. According to Consul Mathews, of Tangier, the almond tree "is remarkable for the facility in raising it, for its hardiness in standing continued droughts, growing in the poorest soils, in the sands, gravels, and amongst rocks; and finally for the abundance of, and high price which its fruit commands. * * * At the sixth year the almond trees commence to yield by far greater product than the expenses incurred in their raising and cultivation, owing to their rustic habit, requiring no care from the time of their planting to the long period which these trees live" (U. S. *Special Consular Reports*, Vol. XI., 1889-90).

The varieties of sweet almond found in commerce are the Valencia, Italian, Barbary, and Jordan. The latter, which are the finest of the sweet almonds, come from Malaga. They are hard-shelled, though they are generally deprived of the shell before being put on the market. The Barbary variety is the smallest and cheapest. The soft-shell (*paper shell*) variety from Majorca of the Balearic Isles, is shipped from Valencia, and French and Italian ports on the Mediterranean coast. They are derived from *Prunus Amygdalus*, var. *fragilis*, De Candolle. The Jordan, or Malaga almonds, differ from all others in being much longer and of larger size. The bitter almonds are imported principally from Mogador, in Morocco. So far as the external appearance goes, they can not be differentiated from the sweet almonds, except the long Jordan variety. Almonds are now cultivated to some extent in California. The bitter variety is said to grow wild in Greece. The almond has been known from the earliest times, having been one of the presents carried down into Egypt by Jacob's sons (*Gen.*, ch. xliii, v. 11). Among the bitter almonds the following are the chief varieties: the French, the best product; the Sicilian; and the Barbary, or least valuable kernel.

Description.—I. *AMYGDALA AMARA* (U. S. P.), *Bitter almond*. "About 25 Mm. (about 1 inch) long, oblong-lanceolate, flattish, covered with a cinnamon-brown, scurfy testa, marked by about 16 lines emanating from a broad scar at the blunt end. The embryo has the shape of the seed, is white, oily, consists of 2 plano-convex cotyledons, and a short radicle at the pointed end, and has a bitter taste. When triturated with water, bitter almond yields a milk-white emulsion, which emits an odor of hydrocyanic acid"—(U. S. P.).

II. *AMYGDALA DULCIS* (U. S. P.)—*Sweet almond*. "Closely resembling the bitter almond (see *Amygdala Amara*), but having a bland, sweetish taste, free from rancidity. When triturated with water, it yields a milk-white emulsion, free from the odor of hydrocyanic acid"—(U. S. P.).

Chemical Composition.—Both varieties of almond contain oil; the sweet, a

fixed oil (see *Oleum Amygdalæ Expressum*); the bitter, a fixed oil (see *Oleum Amygdalæ Expressum*), and a glucoside, called *amygdalin*, capable of splitting into hydrocyanic acid, dextrose, and benzaldehyde (see *Oleum Amygdalæ Amaræ*). The fixed oil may be obtained by expression; it is colorless, or slightly yellowish, sweet and bland to the taste. The essential oil, called *oil of bitter almonds*, consisting of *benzaldehyde* (C_6H_5CHO), and hydrocyanic acid, may be obtained from the bitter almonds by first depriving them of their fixed oil by expression, subjecting the residue to the action of cold water for some hours, and finally distilling the product. The reaction involved is as follows: *Amygdalin* ($C_{20}H_{27}NO_{11}$) is converted, under the influence of *emulsin* (*synaptase*), a vegetable protein ferment present in the bitter and sweet almond, into dextrose, hydrocyanic acid, and benzaldehyde (oil of bitter almonds), as follows: $C_{20}H_{27}NO_{11} + 2H_2O = CNH + 2C_6H_{11}O_5 + C_7H_5O$ (Wöhler and Liebig). *Emulsin* is non-poisonous, and is obtained in an amorphous state. Its activity upon amygdalin is destroyed by boiling heat. Another proteid body, which is likewise soluble in water, is present in the almonds. It was named *conglutin*, by Ritthausen, while Comaille denominated it *amandin*. It is to this body, and emulsin, that the emulsification of oil of almond in water is due. Amygdalin exists only in the bitter almond. On boiling amygdalin in alkaline solution, it splits up into *amygdalic acid* ($C_{14}H_{13}O_7$), and ammonia. With diluted acids, amygdalic acid yields *mandelic* (*phenylglycolic*) *acid* ($C_8H_7O_3$) and grape sugar. In 1895, E. Fischer succeeded in eliminating from the molecule of amygdalin one molecule of dextrose by acting upon it with an aqueous extract of beer yeast. He thus obtained a new glucoside ($C_{14}H_{17}NO_7$), which closely resembles amygdalin, and splits under the influence of emulsin into the same products; it differs from amygdalin in melting point and solubilities. The integuments of almonds contain both cane and grape sugar, the latter predominating, a green, resinous body, and a bitter, yellow principle having an acrid taste (thought to be a glucoside). Tannin has been found in the unblanched kernels. The almonds contain mucilage and protein matter, and yield in the ash, phosphates of calcium, potassium, and magnesium. *Amygdalin* is obtained also from many barks, flowers, seeds, and leaves of plants of the natural order Rosaceæ, those of the sub-orders Amygdaleæ and Pomææ seeming to yield it in considerable amounts.

Amygdalin ($C_{20}H_{27}NO_{11}$), is obtained by freeing bitter almonds from their fixed oil by pressure and extracting the residue with boiling alcohol, evaporating the solvent and recrystallizing the residue. It is a crystalline body, has a sweetish bitter taste, is soluble in cold water (1 in 12), slightly soluble in cold, but easily soluble in hot alcohol, insoluble in ether. It is said to be poisonous, even in the absence of emulsin (Moriggia and Ossi). Its solution is lævo-rotatory. When crystallized, it contains three molecules of H_2O , which is expelled when amygdalin is heated to $120^\circ C.$ ($248^\circ F.$).

Seventeen grains of amygdalin dissolved in 1 ounce of emulsion of sweet almonds, furnishes 1 grain of pure hydrocyanic acid, an amount of acid equivalent to 50 minims of the official diluted hydrocyanic acid. The oil of bitter almonds is a poison acting in the same manner as hydrocyanic acid, unless the acid be removed from it by shaking with milk of lime and ferrous sulphate (Liebig and Wöhler). One drachm of it dissolved in 3 fluid drachms of alcohol, forms an "*essence of almonds*," much used by confectioners, perfumers, etc. The oil of bitter almonds has a golden-yellow color, an agreeable, prussic acid-like odor, and an acrid, bitter taste. It is combustible, burning with a white flame, its specific gravity varying from 1.060 to 1.070; soluble in alcohol or ether, and in water (300 parts); communicates its odor and taste to water, and yields foliaceous crystals of benzoic acid upon standing for a time exposed to the atmosphere.

Action, Medical Uses, and Dosage.—**SWEET ALMONDS.** Triturated with water, sweet almonds produce a white mixture called *emulsion* or *milk of almonds*, which possesses a very remarkable analogy with animal milk; it contains a great quantity of oil, kept in suspension in water by the presence of sugar, gum, and albumen, and is used as a demulcent and as a vehicle for other medicines. The oil, in small quantity, acts as a demulcent; in larger doses it is laxative. It is frequently employed in *cough*, diseases attended with *intestinal irritation*, and for mitigating the acrimony of the urine in *calculous affections*, *cystitis*, *gonorrhœa*, etc.

Externally the oil is sometimes used in lotions and cosmetics. The kernels have been made into a bread, as well as cakes and pudding, to take the place of wheaten bread in *diabetes*. Dose of the oil, 1 to 2 fluid drachms.

BITTER ALMONDS.—Bitter almonds are sedative, and in large doses poisonous. The toxic symptoms and treatment are those of hydrocyanic acid (which see). The oil of bitter almonds, or bitter almond water, is commonly employed, and may be used as a substitute for hydrocyanic acid. Dose of the oil, $\frac{1}{4}$ of a drop to 1 drop, in emulsion, and cautiously increased. Seldom used.

AMYGDALUS PERSICA.—PEACH TREE.

The leaves, bark of twigs, and kernels of the *Amygdalus Persica*, Linné. (*Persica vulgaris*, De Candolle).

Nat. Ord.—Rosaceæ.

COMMON NAME: *Peach tree*.

Botanical Source.—The common peach tree is a well-known medium-sized tree, with spreading branches and a brown, smooth bark. Its leaves are from 3 to 5 inches long and about one-third as wide, bright-green, smooth, lanceolate, and serrate, with all the serratures acute. They are borne on short petioles with 1 or 2 glands. The flowers are axillary, solitary, subsessile, and of a beautiful rose-color, and have the odor of hydrocyanic acid. The petals are 5 in number, and the stamens 25. The fruit is a sub-globular, fleshy, tomentose, yellowish-drupe, tinged with purple, and contains an ovate, compressed, acute, stony putamen which is rugosely grooved and perforated on the surface. The seed enclosed by the putamen resembles the almond in odor, taste, and appearance (W).

Description.—The leaves are lanceolate, finely serrate, from 3 to 5 inches long, smooth on both sides, short petiolate, and green in color. They have a bitter taste and faint odor of hydrocyanic acid. The seeds, though smaller, resemble almonds, chemically and physically.

History and Chemical Composition.—The peach tree is commonly considered to be a native of Persia. It is cultivated in all parts of the United States, where its fruit reaches a greater degree of completion and excellence than in any other country. Its height is from 8 to 15 feet, its fruit is large, being from 1 to 3 inches in diameter, juicy, containing sugar, malic acid, etc., and of a delicious flavor. There are about 200 varieties of this fruit, of which probably one-third are *clingstones*, the flesh adhering to the stone, and the remainder *freestones*, or *clearstones*, the flesh free or separating from the stone. The kernels somewhat resemble bitter almonds, but are smaller, and, probably, possess similar medicinal virtues. They contain *amygdalin*. Hydrocyanic acid can be obtained from most all parts of the tree. Gmelin procured by distillation of the leaves a yellow volatile oil which was heavier than water, and contained hydrocyanic acid. The fixed oil of the seeds is used to adulterate oil of almond, which it resembles. It is known as "*peach oil*." A liquor known as *peach brandy* is distilled from the fermented fruit.

Action, Medical Uses, and Dosage.—Peach leaves in infusion have been recommended in morbid irritability of the bladder and urethra, *pertussis*, *ischuria*, *hematuria*, and *nausea*, as well as in all inflammations of the stomach and abdomen. They act as a sedative in doses of a tablespoonful every hour or two, of the cold infusion; in larger doses they slightly act upon the bowels, and are said to have been useful in removing worms. *Amygdalus* is the remedy for irritation and congestion of the gastric surfaces. It is a very valuable agent in *gastritis* to control the vomiting and allay the extreme irritability of the stomach. Cough depending upon irritation of the throat and bronchial mucous membranes, is amenable to it. Prof. J. M. Scudder has found the infusion useful in *gastro-intestinal irritation*, in *cholera infantum* with nausea or vomiting, in *chronic diarrhoea* and *dysentery*, in *chronic hepatitis*, in *chronic bronchitis*, and in *dyspepsia* attended with gastralgia and nausea. The cold infusion may be freely administered. The kernels are similarly employed in the form of tincture, infusion, or syrup; 4 ounces of the kernels in a quart of brandy is asserted to form a

powerful tonic in *intermittent fever*, and to be remarkably efficacious in curing *leucorrhœa*; dose, a teaspoonful 3 or 4 times a day. Both leaves and kernels give hydrocyanic acid, with emulsin. Poisoning like that from hydrocyanic acid has occurred from the ingestion of peach seed. Infusion (3ss of bark of twigs and leaves to water Oj), 1 fluid drachm to 1 fluid ounce. Specific amygdalus, 1 to 10 drops.

Specific Indications and Uses.—Gastric and abdominal tenderness, irritation, or congestion, with elongated, pointed tongue with reddened tips and edges, and prominent papillæ, nausea and vomiting; intestinal and bronchial irritation, irritative cough; irritative diarrhœa.

Related Species.—*Eriobotrya japonica*. *Loquat*. The leaves and seeds of this tree contain emulsin and amygdalin in amounts sufficient to produce toxic quantities of hydrocyanic acid (*P. J. Trans.*, 1885).

Heteromeles arbutifolia. *Toyon*. California. Contains hydrocyanic, tannic, and gallic acids. (*D. D. Lustig, A. J. P.*, 1882).

AMYL NITRIS (U. S. P.)—AMYL NITRITE.

FORMULA: $C_5H_{11}NO_2$. MOLECULAR WEIGHT: 116.78.

SYNONYMS: *Amyl-nitrous ether*, *Amylæther nitrosus*.

"A liquid containing about 80 per cent of amyl (principally iso-amyl), nitrite [$C_5H_{11}NO_2=116.78$], together with variable quantities of undetermined compounds. It should be kept in small, dark, amber-colored and glass-stoppered vials, in a cool and dark place, remote from lights or fire"—(*U. S. P.*).

Source and History.—Nitrite of amyl was discovered by M. Balard, in 1844, who gave an account of its chemical and physical properties. Chapman and Smith (*Jour. Chem. Soc.*, 1866 and 1867), and afterward Chapman (*Pharm. Jour. and Trans.*, 1871), investigated it carefully. Tanner recommends that it be prepared by a process similar to that of Mr. Redwood for making nitrous ether. Maisch (*Am. Jour. Pharm.*, 1871, p. 147), distills purified amyl alcohol with nitric acid. In all cases the operation requires the utmost care and attention, notwithstanding which by-products will be largely produced which will require careful elimination.

Preparation.—The process of Prof. Maisch, as modified by him from Balard's, is essentially as follows: Mix pure amyl alcohol with its bulk of nitric acid in a rather large glass retort and heat gradually until the reaction commences, then remove the fire and allow the subsequent spontaneous distillation to proceed until the temperature reaches $100^{\circ}C.$ ($212^{\circ}F.$). This distillate only is reserved, as above that temperature considerable nitrate of amyl, and ethyl-amyl ether are produced. The reserved distillate is agitated with solution of caustic potash in order to remove free acids. The decanted liquid is carefully distilled, and those portions only that distill between the temperatures $96^{\circ}C.$ ($205^{\circ}F.$), and $100^{\circ}C.$ ($212^{\circ}F.$), are to be reserved. The yield is small.

Tanner mixes 10 parts of amyl alcohol with 1 of sulphuric acid in a capacious glass retort containing some copper wire; 1 part of nitric acid is added, having been previously diluted with its volume of water. Heat is now applied, and distillation conducted until a temperature of $98^{\circ}C.$ ($208^{\circ}F.$), is reached; the heat is then discontinued, and when the temperature of the liquid within the retort has fallen considerably, another part of nitric acid is added through a safety funnel, and distillation conducted as before. The operation is repeated until the distillate rather more than equals the bulk of the amyl alcohol employed. This constitutes impure nitrite of amyl, and may be purified by the directions given in Prof. Maisch's process.

Description and Tests.—"A clear, yellow or pale-yellow liquid, of a peculiar, ethereal, fruity odor, and a pungent, aromatic taste. Specific gravity, 0.870 to 0.880 at $15^{\circ}C.$ ($59^{\circ}F.$). Almost insoluble in water; miscible, in all proportions, with alcohol or ether. In alcoholic solution it gradually decomposes with formation of ethyl nitrite and amyl alcohol. It is very volatile, even at a low temperature, and is inflammable, burning with a fawn-colored flame. At about 96° to $99^{\circ}C.$ (204.8° to $210.2^{\circ}F.$), it boils, yielding an orange-colored vapor"—

(U.S.P.). When much diluted with ether and allowed to act upon sodium in excess, almost pure nitrogen is produced. If the *nitrite* be in large excess, monoxide of nitrogen (N_2O), is evolved. It is converted by the oxidizing action of chromic acid into nitric acid, valerianic acid, and valerianate of amyl (Chapman and Smith).

"If 1 Cc. of normal potassium hydrate V.S. and 10 Cc. of water be mixed with 1 drop of phenolphthalein T.S., then 5 Cc. of amyl nitrite added, and the tube inverted a few times, the red tint of the alkaline layer should still be perceptible (limit of free acid). On shaking together equal volumes of amyl nitrite and potassium hydrate T.S., the aqueous layer should not acquire a deeper tint than pale-yellow (limit of aldehyde). Amyl nitrite should remain transparent, or nearly so, when exposed to the temperature of melting ice (absence of water). If 0.26 Gm. of amyl nitrite, diluted with about 5 Cc. of alcohol, be introduced into a nitrometer, followed by 10 Cc. of potassium iodide T.S., and afterward by 10 Cc. of normal sulphuric acid V.S., the volume of nitric oxide generated, measured at the ordinary indoor temperature (assumed to be at or near $25^{\circ}C.$, or $77^{\circ}F.$), should be about 40 Cc. (each cubic centimeter indicating about 2 per cent of pure amyl nitrite)"—(U. S. P.).

Action, Medical Uses, and Dosage.—Nitrite of amyl was introduced to the profession as an anæsthetic, in 1863, by Dr. B. W. Richardson, of England; but from many experiments that have subsequently been made, it appears that unconsciousness does not follow its inhalation until its full effects have been experienced, and these effects are due to its absorption by the various tissues of the system. The blood becomes blackish or of a chocolate color, and the absorption of oxygen, as well as the production of carbonic acid, are greatly lessened; and, after a time, from its continuous action, the blood presents a modification appreciable with the spectroscope, and the hemoglobin loses its faculty of crystallizing. From its action vascular and mucous tissues present a dark appearance, the number of pulsations diminish and then increase, the capillaries dilate, arterial tension becomes greatly lessened, and the temperature decreases. Bader and Goodhart, at Guy's Hospital, found that 3 drops of the nitrite, on sugar, occasioned considerable dilatation of the retinal veins, and especially of the papilla of the optic nerve, so as to leave no doubt as to the production of a cerebral hyperemia. Nitrite of amyl likewise possesses a paralyzing influence on both nerves and muscles. Its effects, however, do not appear to be the same with all who inhale it; some are affected by a very minute amount of it, while others require large doses for inhalation, even to 40 drops. With some its action is succeeded by nausea; others, again, will have their vision dimmed, or will be annoyed by a yellow cloud in the field of vision, yellowish and green sparks or rings, and persons around them will appear to be surrounded with a yellow or dark tint. Occasionally, its inhalation is followed by pallor, great depression, and collapse. On these accounts, great care and prudence must be observed in its administration, and especially on the first occasion of its inhalation. With some, repetition of the inhalation appears to lessen its more serious effects; but a too prolonged inhalation should always be avoided, as it is apt to prove fatal. It should not be employed in serious organic diseases of the heart or of the brain.

The usual immediate effects from inhalation of the nitrite of amyl are those observed at first by Guthrie, viz., flushing of the face, throbbing of the carotids, and acceleration of the heart's action. Some patients, after its administration, complain of throbbing in the temples, fluttering of the heart, and a 'death-like' sensation of breathlessness; others feel a tingling throughout the system, or cramp-like pains in the extremities. Dr. Richardson, who introduced nitrite of amyl as a remedial agent, considers its physiological action to be directly exerted upon the ganglionic nervous tract; that it paralyzes so that the nervous supply over the extreme vascular system is impaired; that this paralysis of the nerves travels from the periphery inwards, diminishes muscular contractility, followed by relaxation and dilatation of the capillaries. This effect of the article led Dr. Richardson to suggest it primarily as a remedy for excessive spasmodic action, as in *tetanus*, *angina pectoris*, etc., in which affections it has proved very successful. The action of the nitrite is curative only so far as it controls the spasms present—that is, it prevents death, and thus allows time for recovery, either from the

natural powers of the patient's system, or from the employment of the proper hygienical and therapeutical measures. The various maladies in which it has been successfully employed, are, *angina pectoris*, for which it is the best known palliative, *tetanus*, uncomplicated *neuralgia*, *spasmodic asthma* depending more upon nervous derangement than upon organic lesions, *spasms* of the fibers of involuntary muscles, as in *intestinal colic*, *epilepsy*, *hystero-epilepsy*, *nervous headache*, due to anemia, in which it acts promptly, *chorea*, *syncope*, *puerperal convulsions*, *spasmodic pains* in some of the more important organs of the trunk, *trismus nascentium*, and *intermittent fever*. While its inhalation may cure certain of these affections, it must be borne in mind, that, with many of them, a very prompt and material amelioration of the troublesome or painful symptoms are all that can be expected, as in *epilepsy*, *eclampsia*, *hysteria*, etc. In the *sick-headache*, and other disorders of the menopause, as flushes of heat followed by perspiration, cardiac palpitation, and great prostration. R Amyl nitrite gtt. xv, alcohol flʒj. Mix. Dose, from 1 to 10 drops on sugar, 3 times a day. Amyl nitrite is a good drug in *cardiac dyspnoea* from hypertrophy or *anasarca*. In obstinate *whooping-cough* it gives temporary relief. *After-pains* are said to be promptly checked by its inhalation. Dr. W. E. Saunders (Scudder's *Spec. Med.*, 72), cuts short attacks of *ague* by the inhalation of 2 drops of amyl nitrite or 4 drops of a mixture of equal parts of amyl nitrite and oil of coriander. The inhalation is discontinued as flushing of the face and warmth take place. *Strychnine poisoning* is said to be antidoted by it, used to control the convulsive action.

Chloroform contracts the capillary vascular system, and in several serious cases of *narcosis* following the inhalation of chloroform, the prompt employment of the nitrite of amyl as an antagonizing agent has been successfully resorted to. In *seasickness*, the nitrite has been used with much efficiency. It has likewise been advised in the collapsed stage of *cholera*, by Gamgee and others, but Dr. Brunton has stated, from a doubt whether it dilates the pulmonary capillaries, which are contracted in this disease, that he considers it should be used, if at all, in this disease, either internally or by subcutaneous injection, and not by inhalation; also in *spasmodic asthma*, when the arterialization of the blood is impaired.

In the employment of nitrite of amyl, it is highly important that a pure article be had. When used in inhalation the dose is from 2 to 5 drops, which are to be placed upon a folded linen or handkerchief, and then immediately inhaled for from 3 to 6 minutes. The article is also put up by manufacturers in hermetically sealed glass tears, and called "pearls of nitrite of amyl." As the fluid is exceedingly volatile, this is undoubtedly the best form in which to keep it; and these pearls can be had, each one containing 2, 3, or 5 drops; all that is necessary being to place the pearl in the center of the handkerchief, then crush it, and inhale the vapor. Internally it is rarely employed in doses of from 2 to 5 drops in a small amount of spirit; thus used, its action is very energetic and requires to be closely watched. In *poisoning by chloroform* and in the *collapse of cholera*, 2 or 3 drops may be subcutaneously injected.

Specific Indications and Uses.—Tensive spasmodic disorders of the heart, as in *angina pectoris*; fluttering, irregular pulse; cold and pallid surface; depression; nervous spasms; nervous headache with pallor; dyspnoea from cardiac hypertrophy. In very minute doses in increased throbbing of the arteries; in flushing of the surface, and in burning pain with natural hue of the skin. *Contraindicated* by tendency to apoplexy, brittle or atheromatous arteries, and in predisposition to blood-determination to the brain.

Related Compound.—AMYL NITRAS ($C_5H_{11}NO_3$). *Amyl nitrate*. Specific gravity, 0.902 at 15° C. (59° F.). Boiling point near 147° C. (296.6 F.). This compound is prepared by acting upon amyl alcohol (50 parts by measure), with 150 parts of a mixture of nitric acid (1) and sulphuric acid (2). The amyl alcohol is to be dropped through a tube of considerable length and the mixture accomplished by continuous stirring. The whole is kept cold by a mixture of salt and ice. Impure amyl nitrate rises to the surface as an oily stratum, and is subsequently purified by washing with weak caustic potash solution and water, drying by means of chloride of calcium, and finally rectifying the product. It forms a sweet, oily fluid, without color, and possessing a characteristic odor, and pungent taste. It is insoluble in water, but dissolves in the three alcohols (ethylic, amylic, and methylic), in benzene and glacial acetic acid. It is not used in medicine, and should not be confounded with *nitrite of amyl*.

AMYLENUM.—AMYLENE.

FORMULA: C_5H_{10} . MOLECULAR WEIGHT: 69.85.

SYNONYMS: *Isopentene, Pentene, Valerene.*

Source and History.—Amylene was discovered by Balard, in 1844, who obtained it by distilling amyl alcohol with zinc chloride. It was introduced to the medical profession by Dr. Snow, in a paper presented to the Medical Society of London, January 10, 1857. In the same year, M. Duroy experimented with it carefully, obtaining but $1\frac{1}{2}$ ounces of amylene from 10 pints of amyl alcohol. By his and subsequent investigations it was found that commercial amylene is not a pure article. Its principal constituent is beta-iso-amylene (trimethyl ethylene $[CH_3]_2C:CHCH_3$).

Preparation and Description.—It is prepared by distilling equal parts of amyl alcohol and zinc chloride, by which means amylene and some of its isomers, amyl alcohol, and other substances are obtained. It is to be purified by fractional distillation from chloride of calcium, care being taken that the hydrocarbons of higher boiling point are rejected (see *Pental* below). Amylene is a thin, colorless liquid, having a fragrant odor, being freely soluble in alcohol and ether, and almost wholly insoluble in water. It boils at $35^\circ C.$ ($95^\circ F.$), and has the specific gravity 0.663 at $0^\circ C.$ ($32^\circ F.$). It burns with a bright, smoky flame. Sulphuric acid, previously diluted with half its bulk of water, causes it to polymerize; of the various bodies thus formed, one only, diamylene ($C_{10}H_{20}$), has been more closely studied. Amylene is also known under the name *isopentene*.

Action and Medical Uses.—Dr. Snow introduced this agent as an anæsthetic, but a large amount of it is lost during inhalation, from not being absorbed, besides, death has occurred very suddenly from its use. Unlike the commonly employed anæsthetics, it often produces complete anæsthesia before loss of consciousness, and does not readily nauseate. The French Academy of Medicine gave it a very careful investigation, and rejected it as an uncertain and hazardous agent. It has, therefore, not come into general use, as few physicians would care to replace chloroform or ether by so unsatisfactory an article.

Related Compounds.—*PENTAL.* *Beta-iso-amylene, Trimethylene* ($[CH_3]_2C:CH.CH_3$). Density 0.678. Boils at $38^\circ C.$ ($100.4^\circ F.$). This highly inflammable compound is a purified form of amylum. It is prepared by digesting amyl alcohol with chloride of zinc, and afterwards fractionally distilling the mixture. It is a volatile, colorless fluid, of an odor recalling that of mustard. It is not soluble in water, but dissolves in alcohol, chloroform, and ether. It has been employed as an anæsthetic, requiring but a small amount (less than 6 drachms) to produce insensibility. It is occasionally dangerously depressant to the circulation, and is not likely to come into use, being much less efficient than our commonly employed anæsthetics. It has been employed locally by spray in minor operations.

AMYLENUM HYDRATUM.—*Amylene hydrate, Tertiary amyl alcohol, Dimethyl-ethylcarbinol* ($C_5H_{12}O=[CH_3]_2COH.C_2H_5$). Molecular Weight: 87.81. Density 0.815 to 0.820. Boiling point near $102.5^\circ C.$ ($216.5^\circ F.$). This compound is official in the *German Pharmacopœia*, and is prepared from crude amylene, consisting principally of beta-iso-amylene ($[CH_3]_2C:CH.CH_3$), by shaking it in the cold with sulphuric acid, whereby amyl sulphuric acid is formed, and boiling the latter with water. The product obtained is then subjected to fractional distillation, and that portion of the distillate reserved which distills over between $100^\circ C.$ ($212^\circ F.$) and $102.5^\circ C.$ ($216.5^\circ F.$).

Amylene hydrate is a volatile, limpid fluid, without color, and possessing a pungent, somewhat camphoraceous, mint-like odor, and a sharp, hot taste. It is neutral to litmus, mixes freely with alcohol, benzoin, chloroform, fixed oils, and glycerin, in all amounts, and with water (1 in 8). It should not contain amyl alcohol nor aldehyde. This agent is employed chiefly as a hypnotic. It is of less value in spasmodic disorders. The slumber induced is natural and without stupor, the patient awakening promptly and refreshed, without headache, nor gastro-intestinal disturbances. It is serviceable in the *insomnia of insanity*, and during convalescence from exhausting diseases, and in the *sleeplessness of old age*, or arising from mental overwork, neurasthenia, or alcoholism. From 40 to 75 grains are recommended in red wine, or water flavored with a fruit syrup, or syrup of liquorice. The same amount may be given in mucilage by enema, where organic disease of the stomach prevents its ingestion. Amylene hydrate has also been praised as a remedy in *mania, delirium tremens, the cough of phthisis and whooping-cough*, and in *epilepsy*, especially *petit mal*, and in *nocturnal epilepsy*.

AMYL HYDRIDE (C_5H_{12}).—This product resembles, in some respects, amylene, though its odor is more like that of chloroform, and it has a lower boiling point, $30^\circ C.$ ($86^\circ F.$), than the former. It is obtained from petroleum and coal, being found among the more volatile constituents of the former, and in the light, tarry oil of the latter.

AMYLUM (U. S. P.)—STARCH.

"The fecula of the seed of *Zea mays*, Linné" (U. S. P.).

Nat. Ord.—Gramineæ.

FORMULA: $C_6H_{10}O_5$. MOLECULAR WEIGHT: 161.62.

SYNONYM: Corn starch.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 296.

History and Source.—The ancient Greeks were well acquainted with starch, and its preparation "without the use of a millstone" (hence the name, *amylum*). The process is described by Dioscorides, and later by Pliny, and closely resembles in principle that followed in our days. Beccari, in 1745, showed that gluten may be obtained as a by-product when wheat is used as raw material (R. and S).

The pharmacopœial starch is derived from the seed of the *Maize*, or common *Indian corn plant*, for a description of which see *Zea Mays*. Previous to the present revision (1890), the U. S. P. recognized the starch prepared from the seeds of *Triticum vulgare*, Villars, or *Common wheat*. Starch belongs to the organic compounds called *carbo-hydrates*, and is one of the principal constituents in various organs of many plants, especially in the seeds, where it serves as stored food-material for the growing embryo; also in roots and tubers (potatoes, arrowroot, tapioca), and in the pith of the stems of certain plants, *e. g.*, the sago palm. It abounds especially in the different kinds of grain, among which wheat yields one of its purest varieties, and from which an average of about from 50 to 60 per cent is to be had.

Preparation.—Commercial starch is principally obtained from potatoes and the more abundant cereals. The processes for preparing the various kinds of starch differ to some extent, though all are prepared by comminution of the starch-bearing parts, then separating the starch from the coarser portions by treating with warm or cold water, and allowing the starch to subside. Most cereal starches are prepared as follows: Soak the grain in luke-warm water, to which has been added a little alkali to separate the starch grains from the gluten. After the outer covering of the grain has softened, the material is ground under water and put into sieves and thoroughly washed, over a tank, with pure cold water. The gluten is thereby left upon the sieve, and the starch passes through and is allowed to subside in the tanks. It is then collected and dried in drying chambers, and is ready for use. Starch may be obtained as follows: From wheat flour, which consists of starch, gluten, mucilage, albumen, salts, and bran. The flour is kneaded in a cloth with successive portions of cold water, whereby the gluten and bran remain in the cloth; the mucilage, albumen, and salts dissolve in the water, and the starch passing away with the water, in a state of suspension, gradually falls to the bottom. By allowing the albumino-mucilaginous water, from which it has subsided, to undergo fermentation, the starch is thereby purified from all of the gluten; for the acetic and lactic acids formed during this process dissolve the gluten. The fermentation method is sometimes carried out directly with the wheat, after the latter is softened with water and crushed in roller-mills. The fermented mass is then washed in sacks and fine sieves, as before described. Another method, by which no fermentation takes place, and the gluten may nearly all be saved, is as follows: Allow a stiff dough of wheat flour to stand for a few hours, and then transfer it to a fine wire sieve. While a small stream of cold water plays upon it, knead it until the latter passes clear. The starch may now be thoroughly washed with cold water, drained, and dried. The gluten remains upon the sieve to the extent of 25 parts from 100 parts of wheat flour.

Description and Properties.—Starch, from whatever source, occurs in the form of white granules of varied size and form; these granules are definitely organized structures, although their existence in relation to that of the cell is transitory. They are the first definitely-formed products of assimilation, insoluble in the ordinary cell-sap of the plants containing them, through a process of organization analogous to that by which the development of the cell itself is effected. When these minute granules acquire appreciable dimensions, concentric lines may be observed, more or less distinctly in different cases; a well-

marked example is offered in the granules of the potato-starch. These lines increase in number with the increase of size, in many cases, however, soon becoming eccentric from the preponderating growth of one side of the granule. In freshly extracted granules, the original center generally appears solid, or with a minute black point; but if the starch is dry, the center appears hollow, sometimes is even occupied by air, and some starch grains have a large cavity. If strong alcohol be applied to fresh grains, the abstraction of water likewise produces a hollow in the central point of growth, and in all these cases, cracks not infrequently run out toward the surface. The lines seen in the starch granules are the boundaries of concentric superimposed layers of its substance; sometimes these are very distinct, sometimes very faint; often, more distinct lines appear at intervals in the series of the same granule, and in these cases even, a thin vacancy, or in the dried granules a stratum of air, seems to exist between the layers. The specific gravity of starch is 1.53; its chemical composition is $C_6H_{10}O_5$, or a multiple of this formula.

Starch, according to the U. S. P., made from corn occurs "in irregular, angular masses, which are easily reduced to a fine powder; white, inodorous, and tasteless; insoluble in ether, alcohol, or cold water. Under the microscope appearing as granules, nearly uniform in size, more or less angular in outline, with indistinct striae, and with a distinct hilum near the center. Triturated with cold water, it gives neither an acid nor an alkaline reaction with litmus paper. When boiled with water, it yields a white jelly having a bluish tinge, which, when cool, acquires a deep-blue color on the addition of iodine T.S. When completely incinerated, starch should leave not more than 1 per cent of ash"—(U. S. P.).

Starch, as met with in commerce, is of a granular appearance, friable, insipid, inodorous, permanent in dry air, and in the form of irregular quadrangular or hexagonal columns, emitting a peculiar sound when compressed. In a damp atmosphere it absorbs about 24 per cent of water, without losing its dry appearance; a moderate heat removes its moisture. In its ordinary state it contains about from 12 to 18 per cent of moisture. Starch, well dried by heat, produces with water a rise in temperature of about $15^{\circ} C.$ ($27^{\circ} F.$) [Mærcker].

Following the researches of Naegeli and others, it is now generally adopted that the starch granules consist of three constituent bodies: An external, thin tegument, of the nature of cellulose, not soluble in water, and not attacked by sugar-forming ferments; to the presence of this protecting influence the fact is due that cold water has no action whatever on starch granules as long as they are not crushed. This tegument envelops another substance called *starch cellulose* proper, or *farinose* (formerly named *amglin*), which in turn encloses the bulk of the starch granule, a substance called *starch granulose* (formerly termed *amidon*), soluble in hot water, insoluble in alcohol and ether. The solution of the latter substance in water is powerfully dextro-rotatory, three times as much as cane sugar (Biot). There is, probably, no essential difference between starch cellulose and granulose. The former, under the influence of sugar-forming ferments (ptyaline, contained in saliva, and diastase), may be converted into the same substances as granulose; at ordinary temperature the conversion of starch cellulose takes place very slowly, with the result that it may thus be differentiated from the granulose. In pure condition it is colored yellow by iodine solution.

Warm water at about $87.7^{\circ} C.$ ($190^{\circ} F.$) converts starch into a kind of mucilage, which, when sufficiently concentrated forms, on cooling, a jelly, *starch paste*. When long boiled, the granule almost wholly dissolves, and the decoction on cooling does not gelatinize. Alcohol removes from potato starch a trace of essential oil, on which its odor and taste, when any is present, depend. Pure starch is colored blue by iodine, whether in its natural state or softened by hot water, the depth of the color depending upon the quantity of iodine. Where much is added, the color is almost black. The best application is the solution of iodine in iodide of potassium, and this should be used very weak in the investigation of starch. If iodine be almost a million times diluted, it can be detected by starch. Iodide of starch, when suspended in water and heated nearly to the boiling point, loses its blue color, which returns as it cools; alkalies also remove the blue color; alcohol has the same effect. Boiling with diluted sulphuric acid, also hydrochloric or

oxalic acids, converts starch paste into sugar (dextrose) yielding several intermediary and soluble products collectively called *dextrin*. The latter products are colored yellow or red, not blue, by iodine solution, and the process may thus be traced by the iodine reaction. Dextrin may also be formed by subjecting starch to a temperature of about 204.4° C. (400° F.) (see *Dextrinum*). Starch may be converted for the most part into sugar (maltose) by the ferment *diastase*, a substance into which the protein matter of barley and other grains is converted, after these have been made to germinate, and their vitality destroyed by drying at an elevated temperature; as an intermediary product, *dextrin* (malto-dextrin) is formed. One part of diastase can convert 2000 parts of starch, at 65° C. (149° F.), into dextrin, and a little sugar, or maltose. The dextrin is completely convertible into sugar only by continued boiling with diluted mineral acids. Starch is dissolved by alkalies, from which it is again precipitated by acids, acetate of lead, tannic acid, calcium and barium hydroxides. Upon the formation of an insoluble compound of starch with barium hydroxide is based a method for the quantitative determination of starch, devised by Asboth. When heated, starch melts, turns black, and is decomposed. Nitric acid splits it into malic and oxalic acids. With fuming nitric acid, starch is changed into a white powder, capable of being softened by water, but not soluble in it. It is also insoluble in alcohol. This tasteless powder is a mixture of certain nitrates of starch, called *xyloidin*, an explosive substance discovered by Braconnot (R. and S.).

Action and Medical Uses.—As a constituent of many vegetable substances, starch forms a most important alimentary substance; in a medical point of view, it is to be considered as a demulcent. The powder of starch is used to take up acrid secretions from the external surface, soothe the pain in *erysipelas*, and to prevent *intertrigo* in children; in these affections it is usually dusted on the parts. It is also used in mucilage, or in emulsion for suspending drugs, when to be given internally, or by injection, especially as a lenitive in *inflammation of the lower bowel*. Starch is sometimes triturated with the more active medicines, in order to render them more bulky and easily taken. It is an *antidote to iodine* when swallowed in large quantity.

Other Varieties of Starch.—I. *AMYLUM TRITICI*, *Wheat-starch*. The fecula of the seeds of *Triticum vulgare*, Villars (*Triticum sativum*, Lamarck). *Nat. Ord.*—Gramineæ. This starch was formerly official in the *U. S. P.*, but has been replaced by corn-starch. According to Pereira, wheat-starch, examined under the microscope, consists of large and small grains, the large ones being rounded and flattened, or lenticular; the small ones rather spheroidal. In the middle of the flattened surface is the rounded, elongated, or slit *hilum*, surrounded by concentric rings, which frequently extend to the edge of the grains. When heated, the particles crack at the edges. The grains vary in size from .0001 to .0009 of an English inch. These granules have each a thin exterior pellicle or tegument, insoluble in water, and an interior soluble substance (see *Farina Tritici*).

II. *AMYLUM ORYZA*, *Rice-starch*, *Rice-flour*. Prepared from the seeds of *Oryza sativa*, Linné (*Nat. Ord.*—Gramineæ), or ordinary *Rice*. The latter is deprived of its coverings and palæ, and presents a pearly-white, or translucent, oblong body, about $\frac{1}{4}$ inch in length, with a single groove on one side. Rice starch presents the smallest granules of all the ordinary commercial starches. They consist of polygonal grains more or less adherent to other or larger granules. The rice plant is largely cultivated in subtropical and tropical regions, and quite largely in Southern United States. Its native habitat is India (see *Oryza sativa*).

III. *AMYLUM SOLANI*, *Potato-starch*. The common potato plant is too well known to need a description. It is indigenous to Chili and Peru, and was cultivated at an early date in Virginia from whence the colonists carried it to England. Potato-starch is the principal starch of commerce, and is very largely employed, and is even used to adulterate other varieties, notably arrowroot. It consists of large, irregularly-oval granules intermixed with small subspherical ones. The larger ones present a small hilum at the little extremity and are marked by distinctly concentric lines, giving under the microscope the appearance of a sea-shell.

IV. *AMYLUM CANNÆ*.—*Canna*, *Canna starch*. Probably the fecula of the root of *Canna edulis*, Ker. *Nat. Ord.* Marantacæ.

Canna starch, also known as "*Tous les Mois*," is obtained from a West Indian plant, supposed to be the *Canna edulis* of Ker, the tubers or roots of which are rasped, and then subjected to the ordinary methods of washing, straining, decantation of the supernatant fluid, and drying of the deposited starch. *Canna starch* is imported from St. Kitts, and is an excellent form of arrowroot. *Canna starch* looks more like potato-starch than any other amylaceous substance, has a satiny or glistening exterior, and its particles are large, varying in length from the $\frac{1}{16}$ to the $\frac{1}{8}$ of an inch. Examined by the compound microscope, they are oval or oblong, generally more or less ovate, have a very distinct nucleus or hilum, and fine, regular, uniform, concentric rings. The circular hilum is usually placed at the narrow extremity,

and is very rarely double. The hilum and the body of the particle are frequently cracked. *Tousses Mois* contains about 16.74 per cent of hygroscopic water, is very soluble in boiling water, and yields a very tenacious jelly when boiled in this fluid. Canna starch forms a salutary and agreeable article of diet for invalids and children, and appears to be easily digested. It may be boiled the same as arrowroot, and used in the same cases. By many it is preferred to any other kind of arrowroot.

V. AMYLUM MANIHOT, *Tapioca*.—(See *Manihot*).

VI. AMYLUM MARANTÆ, *Arrowroot*.—(See *Maranta*).

VII. SAGO.—(See *Sago*).

Starch Derivative and Preparation.—DEXTRIN, *Dextrinum* ($C_6H_{10}O_5$). This derivative of starch may be prepared in several ways. On a large scale it is usually prepared by heating starch to a temperature ranging from 226° to 260° C. (438° to 500° F.). It is a whitish-yellow or yellowish, non-crystalline, gum-like mass, or it may occur in granular form, insoluble in ether and alcohol, but readily soluble in water. Its action on polarized light is dextrogyrate, and with an alkaline copper solution occasions no reaction. *White dextrin* has the appearance of starch. It forms a very tenacious, adhesive paste with water, which does not cause the paper on which it is spread, to wrinkle, as do many adhesive mixtures.

AMYLUM IODATUM, *Iodized starch*, *Amyli iodidum*, *Iodide of starch*, *Ioduretum amyli*.—This compound was official in the U. S. P. of 1880, which directed iodine (5 parts) to be triturated with a small quantity of distilled water, and starch (95 parts) to be gradually added, and the trituration continued until a uniform blue (approaching black) coloration ensued. It was finally to be dried at a heat not higher than 40° C. (104° F.), and after rubbing to a finely powdered state, kept in closely secured, glass-stoppered vials. This product is by some thought to be a definite chemical compound, Payen and Fritzsche giving it the formula $(C_6H_{10}O_5)_{10}I$, and Bondonneau $(C_6H_{10}O_5)_5I$. Although it is generally believed to be what Liebig pronounced it, a mixture of finely comminuted iodine and starch, the fact must not be overlooked that iodide of starch may be subjected to a temperature of 100° C. (212° F.) for 6 to 7 days without any loss of iodine being incurred (Stokes in *Maercker's Handbuch*).

Iodized starch is a deep-blue powder, decolorizing in the sunlight. It has a slight odor of iodine. Water heated above 65° C. (149° F.) also decolorizes it, but it again assumes its blue color on cooling. Iodine is partly expelled by boiling with water, and may be wholly driven off by long-continued boiling. Such substances as will readily dissolve iodine, as caustic potash, alcohol, sulphide of hydrogen, and nearly all animal fluids decompose it. The production of iodized starch exhibits the action of the best known test for iodine. The nearer the freezing point, the more perfect are the results of this test. The test is exceedingly sensitive (see *Amylum*). This compound was introduced into medicine as a non-irritating preparation of iodine. Buchanan, of Glasgow, who advocated its use, gave large amounts of it in the course of 24 hours without ill effects. It forms insoluble compounds with many poisons, consequently Bellini recommended it as a general antidote, and further claimed that it assists in the elimination of lead, mercury, and other salts, in cases of poisoning by them. It has been given with success for *lupus erythematosus* (McCall Anderson). A well-rounded teaspoonful may be administered several times throughout the day. As high as 3 ounces have been given in a day, administered in three doses (Buchanan).

ANACARDIUM.—CASHEW-NUT.

The nut of *Anacardium occidentale*, Linné (*Cassuvium pomiferum*, Lamarck).

Nat. Ord.—Anacardiaceæ, Lindley (Terebinthaceæ, Kunth).

COMMON NAME: *Cashew-nut*.

ILLUSTRATION: Strong's *American Flora*, p. 125.

Botanical Source and Description.—The cashew-nut is a small tree, native of the East and West Indies and South America. The leaves are alternate, simple, entire, obtuse, and borne on short leaf-stalks. The flowers are very numerous, small, and fragrant; they are produced in terminal, loose panicles. What is known as the "cashew-apple" is the enlarged juicy peduncle which bears the nut. When ripe, it is of a golden-yellow color, obovate in shape, and has a pleasant, acid flavor, but is somewhat astringent. It is much eaten by the natives. The cashew-nut is attached and hangs from the end of the cashew-apple. It is kidney-shaped, and about 1 inch long. It consists of an edible kernel, surrounded by two shells. The outer shell is smooth and of a bright-brown color. Between the two shells there is a very caustic oily substance which produces troublesome sores within the mouths of those who injudiciously attempt to crush the nut between the teeth, in order to obtain the kernel. When fresh, the kernel is pleasant to the taste,

Fig. 20.

Cashew-nut,
Natural size.

and is largely consumed by the natives. Fig. 20 is a drawing, natural size, of cashew-nut in our possession.

Chemical Composition and History.—The cashew-nut was first examined by Cadet, who found in it gallic acid and an acrid resin. Afterward, De Mattos (*Jour. de Pharm.*, 1831), by a more careful investigation, found, in addition, tannin, an extractive substance, a gum-resin, and some green coloring matter. But the most interesting investigation was made by Stædeler, in 1847-1848 (*Chem. Gazette*, Vol. VI), who examined the viscid liquid contained between the two shells of the nut, having extracted it by means of ether. This liquid is fluid at 15.5° C. (60° F.), congeals at 10° C. (50° F.), is soluble in alcohol and ether, but insoluble in water, and is acrid and caustic; when placed upon the skin, it promptly produces vesication. Stædeler separated this liquid into two constituents, one of which was an oily substance constituting about 10 per cent, fluid at even low temperatures, and forming the vesicating part of the liquid, which he named *cardol* ($C_{21}H_{33}O_2$). This was associated with an acid substance, white and crystalline, when pure, capable of forming salts with bases, some being crystalline, and others amorphous, and to which Stædeler gave the name *anacardic acid*. This acid is not vesicating. Cardol was recently investigated by Spiegel and Dobrin (1895), who established therefor the formula $C_{22}H_{34}O_2 \cdot H_2O$. The tree furnishes a gum in abundance (*gomme d'acajou*, Fr.), which is brittle, and transparent, resembling gum acacia, with the exception of a slight astringency which it possesses. When the trunks of the trees are tapped, a milky juice exudes, which is white when fresh, but turns black on exposure, and, in India, is used as varnish. It stains cotton or linen deep-black by exposure to air. The apple yields a liquor by fermentation, called "cashew wine," which is said to be a wholesome drink. The roasted nuts are edible, care being taken, however, that the fumes from the roasting shell do not come into contact with the face, as thereby painful blisters will be produced upon the exposed portions. A tar is said to be prepared from the pericarp which is used in tarring wood-work and boats, to protect them from the ravages of insects, and the gum from the stems is employed by American bookbinders to insure the bindings from destruction by worms and book-pests.

Action, Medical Uses, and Dosage.—The fresh juice of the rind is very acrid and corrosive, producing redness, tumefaction, inflammation, and blisters, on which account it has been employed in the West Indies for the removal of warts, corns, ringworms, and as a stimulant to indolent ulcers. Blisters formed by its application are apt to be very troublesome and annoying. The kernel, especially when roasted, is edible, having a rather sweet and agreeable flavor. Cardol possesses the activity of the juice of the rind, producing vesication, and in the higher animals, when injected hypodermatically, gastric inflammation, with diarrhoea, followed by stupor and paralysis. The bark of the tree was used by Adanson, to cure himself of the peculiar fever of Senegal; it has an agreeable taste, does not appear to affect the nervous system, has a favorable influence upon digestion, and is very effective in its action, having conquered the *Senegal fever* in cases in which the largest doses of quinine proved unavailable (*Comptes Rendus*, xxvi, p. 254). Prof. Webster (*Dynam. Therap.*, p. 114) suggests its study in *mental disorders*, and states that it has been successfully used in the *mental weakness*, following acute diseases and sexual abuses, in *loss of memory*, *dementia*, and in *failure of nervous power* in the old. From $\frac{1}{3}$ to $\frac{2}{3}$ of a drop of homœopathic mother tincture in water, 4 or 5 times a day, is suggested as the proper dose.

Related Species.—*Anacardium orientale* (*Semecarpus Anacardium*, Linné filius), *Oriental cashew-nut*, India. The nut has similar properties to the cashew-nut. A brown-black oil having strongly vesicant properties, is derived from the mesocarp of the fruit. Serious eruptions of an eczematous nature follow the vesication produced by it, and bloody alvine discharges and disordered urination have resulted from its application. This nut is the *marking-nut* of India. It is there used quite extensively in medicine, being prepared for internal use by boiling it with cow-dung and subsequently washing with cold water. The Hindus use it for *dyspepsia*, *neurasthenia*, *hemorrhoids*, and *cutaneous diseases* (Dymock). The constituents of this nut are probably like those of the cashew-nut, though the brownish oil of the oriental nut differs in giving a green, instead of a red color, in caustic potash solution, and in being precipitated in alcoholic solution, black, instead of red, with basic lead acetate (Basiner, 1881). The nut is described as black, glossy and smooth, about 1 inch in length, subcordate, obtuse, and flattish.

ANAGALLIS ARVENSIS.—RED CHICKWEED.

The leaves of the *Anagallis arvensis*, Linné.

Nat. Ord.—Primulaceæ.

COMMON NAMES: *Red pimpernel*, *Scarlet pimpernel*, *Red chickweed*, *Poor man's weather glass*.

Botanical Source.—*Anagallis arvensis* is a beautiful annual trailing plant, growing in fields, roadsides, etc., introduced into this country from Europe. The stem, which is square, and more or less procumbent, is from 6 to 20 inches long, has elongated branches, or is simple, often dotted with purple. The leaves are sessile, ovate, many-ribbed, opposite or ternate, dotted with purple at the back; the peduncles longer than the leaves; the sepals linear-lanceolate, about equaling the petals; the petals obovate, obtuse, longer than the stamens, and crenate-glandular. The flowers are opposite, small, but beautiful, with scarlet petals opening at 8 o'clock, a. m., and closing at 2 p. m.; in damp weather not open at all. The stamens are purple, hairy, dilated and smooth at the base. Anthers yellow and heart-shaped. Style purple and permanent. Stigma capitate. The capsule is pale and transparent, the size of a pea, separating all round, the valves marked with some indications of longitudinal separations which seldom take effect. The seeds are roughish, abrupt externally, each with a central dot.

History and Chemical Composition.—Red chickweed blossoms from May to August. The leaves are the parts used; they are odorless, but have a rough unsavory taste. Water extracts their virtues. A volatile oil, of the specific gravity 0.980, has been obtained from the dry plant. It has a harsh, pungent taste, and possesses a pronounced odor. Saladin, in 1830, announced that the unpleasant acrid bitterness of the leaves was due to *cyclamin*, a white, poisonous, crystalline principle, while Malapert, in 1857, believed it due to *saponin*. In fact the plant here under consideration, has been usually substituted in Mexico for *Saponaria officinalis*. In 1891, Dr. Schneegeus obtained two glucosides identical with those from quillaja and senega (*Amer. Jour. Pharm.*). A ferment, active in digesting raw meat, has been found (1892) in it (Daccommo and Tommasi), stated to be a white, amorphous mass, soluble in water, with no action upon starch.

Action, Medical Uses, and Doses.—This plant appears to possess energetic properties, for according to Lindley, Orfila killed a dog by "making him swallow 3 drachms of the extract; upon examination it was found to have inflamed the mucous membrane of the stomach." Grenier obtained a similar result. The volatile oil in very small doses (4 drops) produced bodily pain, and persistent, violent "sick-headache." Its virtues are not fully known. It was considered an *antidote to poison* many years ago, and has more recently been employed to prevent the evil results arising from the bite of a rabid animal. Its internal use has been advised in *mania*, *epileptic attacks*, *dropsical affections*, and other derangements of the nervous system, but it should be employed with caution. It may, however, be used in form of poultice, as a local application to old and ill-conditioned ulcers. Dose of tincture (3vij to alcohol, 50 per cent, Oj), from 1 to 5 drops.

Related Species.—*Anagallis cœrulea*, Schreber. *Blue pimpernel*. Distinguished by blue flowers. It was thought by Linné a variety of red pimpernel. Its properties, chemically and medicinally, are probably analogous to those of *Anagallis arvensis*.

ANDIRA.—CABBAGE TREE BARK.

The bark of the *Andira inermis*, Kunth (*Geoffroya inermis*, Swartz; *Geoffroya jamaicensis*, Wright).

Nat. Ord.—Leguminosæ.

COMMON NAME: *Jamaica cabbage tree*, *Cabbage tree*.

Botanical Source.—The *Andira inermis* is a tree of moderate height, with terete, glabrous, ash-colored branches, suberect at their extremities. The leaves are alternate, about 1 foot in length, unequally pinnate; with from five to

eight paired leaflets on short, roundish, ferruginous, downy stalks, oblong-lanceolate, rarely ovate-lanceolate, acuminate, for the most part rounded at the base; they are entire, glabrous, thin, with the nerves, scarcely prominent, about $4\frac{1}{2}$ inches long and 1 inch broad. The petioles are minutely downy, and the stipules lanceolate and persistent. The panicles are terminal, axillary, and erect; the branches subdivided, spreading, angular, brownish purple, and covered with ferruginous down. The pedicels are very short, one-flowered, numerous, and crowded. The flowers are reddish-lilac. The fruit is a hard, one-seeded legume about the size of a large plum.

History, Description, and Chemical Composition.—This tree inhabits the West Indies, especially Jamaica. The bark, as met with in commerce, is in pieces of various sizes, which are thick, whitish, or grayish-brown externally, covered with scales and eroded by lichens; yellow-brown interiorly; furrowed: of a resinous fracture, nauseous odor, mucilaginous and sweetish taste, and pulverulent, the powder resembling that of jalap. This tree was at one time erroneously supposed to be the plant from which Hüttenschmid, in 1824, obtained his *jamaïcine*, that was subsequently (1865) identified as berberin by Gastell. However, Hüttenschmid, in 1824, isolated from the genuine *Andira* bark a supposed alkaloid, which he called *surinamine*. This was reobtained by O. Hiller-Bombien, in 1892, from an authentic specimen of *Andira inermis*, Kunth, and ascertained to be methyl-tyrosin, an amido acid of the formula $C_{10}H_{11}NO_3$, which he found identical with the *ratanhin* of Rupe and the *angelin* of Gintl (1869). He finally named it *andirin*. It occurs in white needles, is tasteless and neutral to litmus, easily soluble in hot water, but sparingly so in cold water, ether, or alcohol. The name *andirin* had been applied before to other, probably more active, constituents of the plant—e. g., by Midy to a glucoside—and Peckolt, in 1859, applied the same name to a brown-yellow coloring matter from *Andira anthelmintica*, Benthams (see below) (*Amer. Jour. Pharm.*, 1889).

Action, Medical Uses, and Dosage.—Cabbage tree bark is emetic, purgative, and anthelmintic. It is thought by some to be a dangerous acro-narcotic in large doses, causing troublesome sickness, fever, and delirium, on which account it is not much used in practice, although it has proved effectual in removing the *lumbricoid* worms. The bark in powder may be given in doses of from 10 to 30 grains; of the decoction, 1 tablespoonful 2, 3, or 4 times a day. Any unpleasant symptoms resulting from its administration may be obviated by a dose of castor oil, and a free use of lemon juice or lime juice.

Related Species.—*Andira retusa*, Kunth (*Geoffroya retusa*, Lamarck). Habitat, Surinam. Source of Surinam bark. "The Surinam bark has a grayish epidermis, covered with lichens; dark brown, lamellated, very tough, compact; when cut across, brilliant and variegated brown; when recent, nauseous; no smell when dried; taste a little acrid and bitter; powder pale cinnamon." The bark abounds in tannin. It is frequently asserted that Hüttenschmid found his *surinamine* (see *Andira inermis*) in this bark, but modern researches do not favor this view (E. Schar, 1893, and O. Hiller, 1892).

Andira anthelmintica, Benthams (*Geoffroya vermifuga*, St. Hilaire). Brazil. This tree contains, according to Peckolt, a yellow-brown coloring body, called *andirin*. The seeds of this forest tree are yellow and about the size of nutmegs, and are reputed to possess anthelmintic properties. They are known as *angelin amargosa*. The purgative and vermifuge properties are due to an acrid resinous body, soluble in both alcohol and ether. The sawdust, when inhaled by those who cut the trees down, produces conjunctivitis, great thirst, with faucial constriction, and has a burning, bitter taste. Itching of the integument and occasionally skin eruptions result from it (Peckolt).

Andira Araroba, Aguiar (see *Araroba*).

ANEMONE NEMOROSA.—WIND FLOWER.

The whole plant of *Anemone nemorosa*, Linné.

Nat. Ord.—Ranunculaceæ.

COMMON NAMES: Wind flower, Wood anemone, Wind crowfoot.

ILLUSTRATION: *Drugs and Medicines of North America*, by J. U. and C. G. Lloyd, Vol. I, p. 22.

Botanical Source.—"This is a graceful little plant, about 4 inches high, which blossoms in early spring, and is found in open woods. The root is a slen-

der, horizontal root-stalk. The stem, which is produced from the extremity of the root-stalk, is simple, slender, erect, and leafless, except at the top, where it bears a whorl of three-petiolate, three-parted floral leaves, and a solitary, small, peduncled, white, or purplish flower. This little plant is of wide distribution in this country and also in Europe" (C. G. Lloyd, in *Drugs and Medicines of North America*, p. 21).

History and Chemical Composition.—This plant blossoms in April and May. "*Anemone nemorosa* abounds in an acrid juice, which is particularly intense in the root. These properties disappear when the plant is dried, and hence only the recent plant, or preparations of the recent plant, are of value in medicine. In consequence of this fact, the dried plant is not a commercial drug, and doubtless, like others of this family, the uncertain nature of the plant when dry has prevented it from becoming a recognized remedy" (Prof. J. U. Lloyd, in *Drugs and Medicines of North America*, p. 22).

The acrid properties of this plant are due to a principle subsequently mentioned—a principle that is dissipated even in drying the plant; hence the dried drug is practically inert. According to Prof. J. U. Lloyd (*Drugs and Medicines of North America*, p. 22), a tincture of the fresh plant affords the only reliable representative of the drug. According to Linnæus, it produced in cattle feeding upon the plant both dysentery and bloody urine.

Anemonin ($C_{10}H_8O_4$) Beckurts, 1892, occurs not only in the herbs of *A. nemorosa*, but also of *A. Puls-*

Fig. 22.
Crystals of Anemonin crystallized from chloroformic solutions.

satilla, L., *A. pratensis*, L., *Ranunculus reptans*, L., *R. acer*, L. (45 pounds yielded 11.5 Gm.) and *R. sceleratus*, L., and the leaves of *Clematis angustifolia* and *C. integrifolia*. It is obtained by distilling the plants with water, and either setting the product aside, allowing it to crystallize, or shaking out the distillate with chloroform. From this solution anemonin first crystallizes, and afterwards a substance called *anemone camphor*, which is a very unstable compound having a sharp odor, irritating the mucous membranes of the nose, etc. It readily splits into *anemonin* and amorphous *isanemononic acid*. To this property of anemone camphor are accredited the evanescent physiological properties of the drug.

Anemonin forms white needles having a fusing point at 150 to 152° C. (302 to 305.6° F.). It is without odor and taste, and of neutral reaction to litmus, but acquires a burning taste when melted. It volatilizes with the vapors of boiling water, and is quite irritating under this condition. It is slightly soluble in cold water and alcohol, more readily in chloroform and fixed oils, but not in ether. Alkalies readily combine with it. *Anemononic acid* ($C_{10}H_{10}O_6$) also occurs in the herb, together with *anemoninic acid* ($C_{10}H_{12}O_6$). The former, occurring in white needles with the fusing point 250° C. (410° F.), may be obtained by boiling anemonin with lead oxide; the latter by warming anemonin with diluted acids (Beckurts, *Amer. Jour. Pharm.*, 1892).

Action, Medical Uses, and Dosage.—This plant is acrid and poisonous. It has been recommended in *amaurosis* and other diseases of the eye, *secondary syphilis*, *cutaneous diseases*, and *whooping-cough*, in doses of 1 or 2 grains daily. These, however, are its old-time uses. When applied locally it is said to be efficient in *scald-head*. In the recent state, the leaves bruised and applied to the skin are rubefacient. In large doses this article produces nausea, vomiting, looseness of the bowels, and hematuria. Prof. Edwin M. Hale, M. D., states that it is not in use

Fig. 21.

Anemone nemorosa.

among the homœopaths, and that he has heard of several cases of poisoning by it in which the toxic effects were similar to those of pulsatilla, but much more severe. He suggests that as a remedy it might occupy a place between aconite and pulsatilla (*Drugs and Medicines of North America*). Prof. Scudder (*Spec. Med.*) writes: "It influences the functions of waste and repair, but works directly upon the nervous system." The remedy will repay study, and is suggested as of probable value in *skin diseases*, and, we might add, *nervous derangements*. The drug referred to by Webster as "*Pulsatilla Nuttalliana*," or "*Anemone nemorosa*," is undoubtedly *Anemone patens*, var. *nuttalliana*, which see. A tincture of the fresh plant in fruit (3vijj to alcohol Oj) may be tried in doses of a fraction of 1 drop to 5 drops.

Related Species.—*Anemone cylindrica*, Gray. United States. Distinguished by cylindrical fruit-heads. Used by the Indians for the cure of rattlesnake bite. Their mode of using it is to chew some of the tops of the plant, swallowing but little of the saliva, and then applying it to the bite; in a few minutes the poison is rendered harmless. When chewed the tops have a hot, pungent taste, somewhat like capsicum. All the anemones are useful in *menstrual suppression*, and all are likewise acrid and poisonous.

Anemone virginiana, Linné. *Wood flower*, *Wind flower*, *Thimble weed*. An herb growing from 2 to 3 feet high, having from 2 to 4 greenish-white flowers; distinguished also by its oblong head of wooly achenes. Reputed to have similar properties to those of *Anemone nemorosa*. According to Kalm, the seeds relieve *toothache* if dipped in alcohol and placed in the tooth cavity. Porcher states that it will remove *corns* (*Drugs and Medicines of North America*, Vol. I).

Anemone patens, var. *Nuttalliana* (see *Anemone patens*).

Anemone coronaria, Linné. Levant. Occasionally cultivated. Used medicinally to a slight extent.

Anemone cernua, Thunberg. *White-headed old man*. China and Japan. Root used medicinally.

Anemone sylvestris, Linné. Europe and North Asia. This and the next species employed by the Siberians.

Anemone ranunculoides, Linné. Europe and Siberia.

Anemone pratensis, Linné, and *A. Pulsatilla*, Linné (see *Pulsatilla*).

ANEMONE PATENS.—AMERICAN PULSATILLA.

The flowering plant *Anemone patens*, Linné; var. *Nuttalliana*, Gray. (*Anemone Ludoviciana* Nuttall; *Anemone Nuttalliana*, De Candolle; *Pulsatilla Nuttalliana*, Sprengel).

Nat. Ord.—Ranunculaceæ.

COMMON NAMES: *American pulsatilla*, *Pasque flower*.

ILLUSTRATION: *Drugs and Medicines of North America*, by J. U. and C. G. Lloyd, Vol. I, p. 27; Meehan's *Native Flowers*, I, 49.

Botanical Source and History.—"*Anemone patens* is a very conspicuous flower in early spring, found in prairie regions of Illinois, thence west to the Rocky Mountains, and northwest. The stem rises about 4 inches out of the ground, and is terminated by a large, erect, solitary, light bluish-purple flower. Below the flower, encircling the stem, is a many-parted floral leaf, covered with silky hairs, as are all parts of the plant. The true leaves are not expanded at flowering time, but are afterwards developed from the root of the plant, and are palmately divided into many linear lobes. The fruit is a head of achenes, with long, silky tails. It is borne on a stalk which is greatly elongated after the plant has flowered" (C. G. Lloyd, in *Drugs and Medicines of North America*, Vol. I, 26).

The plant has a faint, camphor-like odor, and a somewhat saccharine taste in the dried flowers; the recent flowers and leaves are very acrid and irritating, which properties are considerably lessened by drying, owing to the evaporation of a volatile, acrid principle. The fresh plant will vesicate, and the vapors of the fresh juice have produced severe conjunctivitis. Simple contact with the plant produces severe irritation. The drug was introduced to the profession by Dr. W. H. Miller, and F. B. and A. W. Miller (sons), all of St. Paul, Minn. It was introduced to Dr. Miller by an Indian, who declared it the "great medicine" of the Northwestern tribes of Indians. This plant bids fair to supplant foreign pulsatilla in the American drug market (*Drugs and Medicines of North America*, Vol. I, 28).

Chemical Composition.—Mr. A. W. Miller (1862), proved the existence of a volatile acrid principle in this plant, and by agitating the aqueous distillate with

chloroform he obtained an acrid white principle which he believed to be *anemonin*, though the amount was too small for verification. His brother, Mr. F. B. Miller, re-examined the plant in 1873, and by the same process obtained white, feathery crystals of a neutral reaction at first, but becoming both acid and colored in a few days. A distillate of the fresh juice preserved in alcohol was also distilled by him, and treated with chloroform, from which brown

acid crystals were obtained. A quantity of the dried herb was then distilled, and subsequently treated with chloroform, as above, without obtaining the acrid principle yielded by the fresh herb. Hence, it seemed conclusive that the anemonin is dissipated in drying, and this also appears true from the fact that the dried herb has none of the irritating properties of the fresh plant, and upon chewing the herb a year old only a slight tingling sensation was produced. In fact it was scarcely more than astringent. Glucose, tannin, two resins, pectin, calcium and magnesium salts, sulphates, and the ordinary plant constituents were also found by Miller. Albumen was absent (see Prof. J. U. Lloyd, *Drugs and Medicines of North America*, Vol. I, 29).

Flower of *Anemone patens*, var. *Nuttalliana*.

Anemone patens, var. *Nuttalliana*, with fruit.

For further details on constituents, see *Anemone nemorosa*.

Action, Medical Uses, and Dosage.—This plant has been found useful in many chronic cases of ophthalmic maladies, as *cataract*, *amaurosis*, and *corneal opacity*; also in *cutaneous eruptions* and *secondary syphilitic diseases*. It has likewise effected cures in uncomplicated *amenorrhœa*, *leucorrhœa*, *pains in the testes*, or *ovaries*, and along the *spermatic chord*, sharp, cutting *gastric pains*, *frontal headache* in *onanists*, and in *chronic irritation of the nerves*. It will also be found useful in *reflex paralysis*, *obstinate hiccough*, *chorea*, and in *chronic mucous diseases* generally. The foregoing statements constitute a summary of the uses of the drug as gleaned from European and early American observers and are the cases in which large doses were employed. Many of these statements, however, require confirmation. According to Dr. W. H. Miller, it is a good *pile* remedy (*Drugs and Medicines of North America*). Prof. Edwin M. Hale, the distinguished homœopathist, found upon investigation, that its properties were practically identical with those of European *pulsatilla*. (See *Drugs and Medicines of North America*, for homœopathic uses). This is undoubtedly the drug referred to by Prof. H. T. Webster (*Dynam. Therap.*), as "*Pulsatilla Nuttalliana*," or "*Anemone nemorosa*." Owing to its probable identity with *pulsatilla*, this drug will undoubtedly prove a reliable substitute for the European species, and be used for similar purposes and in the same doses (see *Pulsatilla*). The U. S. P. (1880), recognized it as a source of *pulsatilla*. Five to 30 drops of the tincture (3vij to alcohol Oj), may be added to 4 fluid ounces of water, a dose of which is a teaspoonful 3 times a day.

ANEMONIN. A solution of anemonin has been used externally in *scald-head*, *ulcers*, *caries*, *indurated glands*, *venereal nodes*, *serpiginous affections*, *paralysis*, *amaurosis*, *cataract*, and *opaque cornea*. Its internal use is questionable. It has, however, been employed in *bronchitis* and in *convulsive forms of cough*, as in *whooping-cough* and *asthma*. Experiments upon the lower animals indicate that it possesses paralyzing properties, particularly directed to the cardiac and respiratory functions.

ANEMOPSIS CALIFORNICA.—YERBA MANSA.

The root of *Anemopsis californica*, Hooker.

Nat. Ord.—Saururaceæ.

COMMON NAME: *Yerba mansa*.

Botanical Source and History.—This is a perennial herb, a native of wet places in Southern California and in the northern part of Mexico. The stem is erect, about a foot high, and bears a close, terminal spike of flowers. Near the middle of the stem is borne a large clasping leaf from the axis of which a few short, slender branches are produced. The leaves are mostly in a radical cluster at the base of the stem; they are from 2 to 4 inches in length, one-half as broad, of a firm, leathery texture, smooth and entire; their outline is oblong, with a cordate base. The leaf-stalks are about the length of the leaf, dilated at the base, and pubescent along the margin. The stem is remarkable for sending out from its base, slender, unbranched stolons, from 3 to 6 feet long. These stolons are of rapid growth, and produce at intervals of about a foot, roots and a cluster of leaves, which in another year become a separate plant. The flowers are small, and borne in a thick, dense spike (spadix), about an inch in length. At the base of the spadix are about 6 large, petaloid, involucre leaves in the same manner as the flowering dogwood, which give to the entire inflorescence the appearance of a single terminal flower. The flowers are small, and destitute of either corolla or calyx, but are each subtended by a small colored bract. The stamens are about 6, with short filaments, and borne on the ovary. The stigmas are generally 3, spreading, and about as long as the stamens. The ovary is 1-celled, immersed in the spadix, and consolidated with it. The seeds are small, light-brown, and attached to the parietal placenta of the capsule. There is a pungent, disagreeable, somewhat aromatic odor, and a sharp, biting taste, imparted by all parts of the plant, when chewed, followed by a sense of astringency.

History and Description.—The Indians of Southern California, Mexico, and Arizona, according to Dr. Palmer (*Amer. Jour. Pharm.*, Dec., 1878), employ both the roots and leaves of this plant. Dr. William H. George, of California, first brought the drug to our notice, the root being the part employed. When dried, the roots are of a brown color, wrinkled, from $\frac{1}{4}$ inch to $\frac{1}{2}$ inch in diameter, and seem to grow mostly horizontally near the surface of the ground. From 4 to 10 fleshy rootlets spring in a clump from one side of the root at the base of the leaves, and run downward. A strange peculiarity of the lot of roots examined by us, is, the presence of numerous grass stalks that pierce and grow through them, sometimes appearing several inches from the place of entrance. Internally, the root is pinkish; and, running lengthwise through it, about midway between the surface and the center, is a ring of coarse, fibrous, medullary matter. The upper portion of the root is not infrequently brown and half decayed.

Chemical Composition.—The active principles of this root are freely extracted by alcohol; they are, firstly, about 5 per cent of a volatile oil, which is heavier than water, is soluble in ether, alcohol, chloroform, and disulphide of carbon, and possesses the exact odor and taste of the plant. This oil turns blue when agitated with hydrochloric acid. Secondly, a vegetable tannate, which forms a black precipitate with ferrous sulphate. There is no alkaloid, or other body present, worthy of notice (*Amer. Jour. Pharm.*, Jan., 1880).

Action, Medical Uses, and Dosage.—This plant was introduced to the profession by Dr. W. H. George, of California. He states that the natives esteem it a panacea far excelling the Yerba santa, and successfully employ it in all malarial fevers, in diarrhœa, and in dysentery (*Eclectic Med. Jour.*, 1877, p. 238). In a letter to Prof. King, he observes that the natives frequently carry the root with them, chewing it and swallowing the juice, and consider it a certain remedy for cough and pulmonary affections. They likewise employ a strong infusion of it as an efficacious local application to saddle and collar galls on horses. Dr. George considers it a stimulant tonic, astringent, carminative, and anti-emetic. He has successfully employed it in gonorrhœa with profuse discharge, and thinks it equal to cubebs in this disease, and more pleasant to take. Prof. King has tried it in one case of gonorrhœa, and in several cases of bronchial cough, with favorable results. The dose of the fluid extract is from 10 to 60 minims, in syrup, repeated every 3 or 4 hours.

Related Species.—*Saururus cernuus*, Linné. *Nat. Ord.*, *Saururaceae*. A common perennial known as *Lizard's tail*, found in swampy grounds in North America. Whitish flowers, borne upon a slender spike, recurved at the top; fruit fleshy and berry-like. The plant has a sub-acrid taste and a disagreeable, aromatic odor. Its constituents have not been determined. The decoction is freely used in *irritative disorders of the gastro-intestinal tract and urinary apparatus*, particularly *strangury*. As a poultice the root has been applied to painful *inflammatory swellings* and to various kinds of *abscess*.

ANETHI FRUCTUS.—DILL-FRUIT.

The *Anethum graveolens*, Linné. (*Peucedanum graveolens*, Hiern.)

Nat. Ord.—*Umbelliferae*.

COMMON NAMES: *Dill seeds*, *Dill fruits*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, p. 132.

Botanical Source.—This plant is an annual, bearing large yellow flowers, disposed in flat umbels. It reaches a height of from 1 to 2 feet, and has delicately striated stems, bearing pinnate leaves composed of long, setaceous leaflets. The whole plant is glaucous. The root is long and fusiform.

History.—This plant is indigenous to Southern Russia and other Mediterranean regions; also to the Caucasian territories. It is cultivated in Europe, thriving as far north as the Scandinavian peninsula. It occurs in some sections as a common weed in cornfields. It is cultivated to a very limited extent in this country. It is scarcely used here as a medicine, but enjoys considerable reputation in England, where it holds a place in the *British Pharmacopœia*. It is said to have been known to Dioscorides, and is now regarded as the plant mentioned in the Scriptures (*Matt.*, ch. xxiii, v. 23).

Description.—ANETHI FRUCTUS. *Dill-fruit*. The seeds are oval or ovoid, seldom longer than $\frac{1}{4}$ inch, convex or flattish on one side, concave on the dorsum, which is striated or marked with piliform ridges 5 in number, the two outer ribs becoming blended with the thin, membranaceous margin surrounding the fruit. The 3 central or dorsal ridges are sharply keeled. Six vittæ (oil cells), are usually present, 4 between the ribs and 2 on the commissure. The mericarps separate when mature, are about $\frac{1}{16}$ inch in width, and of a brown color. The membranous marginal wings are of a yellowish color. The fruit has a strongly aromatic odor and taste. The fruit grown in India is smaller, not so broad, more prominently ribbed, more convex, and the margin less winged. Otherwise it resembles the above described European fruit.

Chemical Composition.—Dill-fruit yields a volatile oil to which its properties are probably due. This oil is obtained to the extent of 8 or 4 per cent, and was found by Gladstone to consist mainly of *anethene* ($C_{10}H_{16}$), a hydrocarbon having the odor of lemons, strongly dextrogyre, with boiling point at $172^{\circ}C$. ($341.6^{\circ}F$.), and density of 0.846. Two other bodies have also been found (see *Oleum Anethi*).

Action, Medical Uses, and Dosage.—Carminative and stomachic, and used in the preparation of dill-water. The natives of India use the fruit largely in medicine and cookery. *Flatulent colic* and *singultus*, when due to disordered digestion, are relieved by the administration of dill-water or the oil of dill; the former in 1 or 2-drachm doses, the latter in from 2 to 5-drop doses on sugar. It possesses no advantages over the other aromatic seeds.

ANGUSTURA.—ANGUSTURA BARK.

The bark of *Galipea Cusparia*, St. Hiliare (*Galipea officinalis*, Hancock; *Cusparia febrifuga*, Humboldt; *Galipea febrifuga*, Baillon; *Bonplandii trifoliata*, Willdenow).

Nat. Ord.—*Rutaceae*.

SYNONYM AND COMMON NAMES: *Cusparize cortex*, *Cusparia bark*, *Angostura bark*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 43.

Botanical Source.—This tree seldom exceeds 20 feet in height, with a stem whose diameter is from 2 to 6 inches, having irregular branches, and a smooth bark. The leaves are alternate, trifoliate, and petiolate; the leaflets oval,

acute at the base, acuminate at the apex, smooth, glossy, bright-green, having a tobacco-like smell when fresh and bruised, from 6 to 10 inches long, 2 to 4 broad, some of them marked with small, whitish, round spots. The petiole is about the length of the leaflets, and slightly channeled. The flowers are white and beautiful, with a narcotic odor, and are borne in cylindrical, contracted, stalked panicles, longer than the leaves, the branches being about three-flowered. Calyx inferior, campanulate, five-toothed, hairy; corolla somewhat curved before expansion, nearly an inch long, downy on both sides; of the five petals, two larger than the others. Sterile stamens, five, subulate, tipped with a pellucid, watery gland; fertile stamens, two; style, erect; stigma, simple. The fruit or carpels are five, or fewer by abortion, becoming villous as they mature, two-seeded, with a strong, elastic, separable, two-valved endocarp (L.).

History.—There has been heretofore some uncertainty relative to the tree from which the official angustura bark is obtained, but the question has been definitely settled by Dr. Hancock, who has ascertained that it is chiefly the product of a tree to which he has given the above name. *Galipea officinalis*, now *Galipea cusparia*, is official in the *British Pharmacopœia*. Under Hancock's name, it was formerly official in the *U. S. P.* It is found growing in great abundance in the missions of Carony, Tumeremo, etc., and other parts of Columbian Guiana.

Description.—The bark, as imported from the West Indian ports, is in flat pieces or incomplete quills, from 2 to 4 or even 8 inches long, 1 or 2 inches in breadth, and 1 or 2 lines in thickness. Its outer surface is dirty-grayish-yellow in color, often speckled in the smaller pieces with lighter gray spots and elevations; the inner surface is dull-brown; and the substance of the bark is yellowish-brown. It breaks easily, the transverse fracture being smooth and somewhat resinous in appearance; and presents white, shining striae, produced by aggregations of crystalline, calcium oxalate; its powder has a grayish-yellow color, somewhat like that of rhubarb. When soaked in water, it is soon softened sufficiently to be easily divided by means of shears. It has a characteristic, unpleasant odor, and an intensely bitter, somewhat aromatic and acrid taste. Water, alcohol, or proof-spirits take up its virtues.

Chemical Composition.—Fischer found in it a volatile oil 0.3, peculiar bitter principle 3.7, bitter hard resin 1.7, balsamic soft resin 1.9, elastic resin 0.2, gum 5.7, lignin 89.1. By submitting the bark to distillation with water, a yellowish-white, odorous, acrid, volatile oil is obtained, which is not so heavy as water. The bark also contains nearly 1.5 per cent of a peculiar neutral, crystalline principle, named *cusparin* by Saladin, and termed the *peculiar bitter principle* by Fischer. *Cusparin*, or *angosturin* (Pereira), is obtained by submitting the alcoholic tincture of the bark (prepared without heat) to slow atmospheric evaporation; the crystals thus obtained are to be purified by repeated crystallization from alcohol and agitation with ether and hydrated oxide of lead. It forms tetrahedral crystals, is fusible at 44.4° C. (112° F.), and loses 23.09 per cent of its weight; cold water dissolves $\frac{1}{2}$ per cent and boiling water 1 per cent of it; it is freely soluble in alcohol, but not in ether or volatile oils; readily dissolves in the concentrated acids, and more sparingly in the alkalies, and its acid solution yields a whitish precipitate with the tincture of galls (Saladin, *Jour. de Chim. Med.*, IX, 388).

Cusparin, obtained in the cold, occurs in needle-like crystals. It is inflammable. The volatile oil, which has a boiling point at 266° C. (511° F.) is represented, according to Herzog, by the formula, $C_{15}H_{24}O$. Oberlin and Schlagdenhauffen, who examined the bark in 1878, found volatile oil, resin, fat, dissolved by alcohol; wax, fat, and stearic acid dissolved by benzin; moisture; and a bitter, yellow body, which yielded a crystalline alkaloid called by them *angusturine* ($C_{10}H_{16}NO_4$). It is fusible at 85° C. (185° F.), turns green when treated with sulphuric acid mixed with oxidizers—as nitric acid—but with pure sulphuric acid a red coloration ensues. In 1892 Beckurts and Nehring made a detailed investigation of the bark, isolating therefrom the following four alkaloids: *Cusparine* ($C_{20}H_{19}NO_3$) fusing point 98° C. (208.4° F.); readily soluble in alcohol and ether, its salts being difficultly soluble; *cusparidine* ($C_{19}H_{17}NO_3$) fusing point 78° C. (172.4° F.); *galipine* ($C_{20}H_{21}NO_3$) fusing point 115.5° C. (240° F.), and *galipidine* ($C_{19}H_{19}NO_3$) fusing point 111° C. (231.8° F.), the proper crystallizing solvent for the latter three alkaloids being light petroleum. The authors found, besides

an essential oil extracted by means of ether. *angusturine*, a bitter principle insoluble in ether, having a fusing point of 58°C . (136.4°F .), and a glucoside not further examined. The bark was previously studied also by Koerner and Boehringer, in 1884, who found three alkaloids, one being identical in composition and fusing point with the *galipine* of Beckurts and Nehring.

Substituted Barks.—Some years since a poisonous bark was introduced as the true bark, and the administration of which was attended with fatal results. This spurious bark was at first supposed to be the product of the *Brucea ferruginea*, but is now recognized as the bark of *Strychnos Nux vomica*. It is known as the FALSE ANGUSTURA BARK, and may be detected by the following marks: The genuine bark has a strong and disagreeable odor; a bitter, durable, pungent taste; softens in water, and imbibes it quickly; is very light; tissue not compact; has a resinous, shining fracture, and when touched with nitric acid becomes colored a dull red; the false bark has no odor; an insupportably bitter, very durable taste; does not soften sensibly in water; is very heavy and compact; has a dull and blackish fracture, and nitric acid turns its fractured surface bright red and its rusty epidermis an intense green. The false bark is rarely met with in this country (Duncan). It contains *brucine*.

A bark known as *Brazilian angustura*, derived from *Esenbeckia febrifuga*, Martius, (*Evodia febrifuga*, St. Hilaire), and collected in Brazil, has been met with in substitution for angustura (Maisch, *Amer. Jour. Pharm.*, 1874, p. 414). It occurs in pieces a little curved, and having a thickness of about $\frac{1}{4}$ inch. It is very bitter, but not aromatic to the taste, nor does it swell when macerated in water. The inner layers are deep-brown, over which are blotches of a soft, corky layer of a brown-gray hue, having internally a faint, orange-rusty brown color. Its fracture is short and fibrous, and there is an absence of the white, shining striæ, due to the raphides of calcium oxalate found in the true bark. Oberlin and Schlagdenhaufen found in the Brazilian product an alkaloid turning yellow-green upon treatment with sulphuric acid. To this principle they gave the name *evodine* (*esenbeckine*), and the formula, $\text{C}_8\text{H}_{10}\text{NO}_6$.

Oberlin and Schlagdenhaufen record the following additional substitutions of angustura bark: Guaiacum bark, Copalchic bark, and the barks of *Cinchona bicolorata* and *Samadera Indica* (*Amer. Jour. Pharm.*, 1879, p. 83).

Action, Medical Uses, and Dosage.—In large doses, of from 20 to 60 grains, it is emetic and cathartic; in doses of from 5 to 15 grains, non-astringent tonic and febrifuge. Recommended in *bilious diarrheas* and *dysenteries*, *intermittents*, *dropsies*, etc. It is seldom used, on account of its liability to adulteration with the poisonous bark of the *Strychnos Nux vomica*, known as the *False angustura bark*. Dose of the bark, 10 to 30 grains; of the infusion (3ss in Oj), 1 to 2 fluid ounces.

ANILINUM.—ANILINE.

FORMULA: $\text{C}_6\text{H}_5\text{NH}_2$. MOLECULAR WEIGHT: 92.83.

SYNONYMS: *Phenylamine*, *Amidobenzene*, *Anilina*, *Anilin*, *Phenamid*.

History and Source.—Aniline is named from the Portuguese *anil*, meaning indigo, from which aniline was first obtained. This name was given to it by Fritzsche, in 1841, though it was first discovered by Unverdorben, in 1826, who obtained it by dry-distilling indigo, and named it *crystalline*. In 1834 Runge obtained from coal-tar three volatile bodies, among them one which, on account of the beautiful, dark, violet-blue color produced with chlorinated lime, he named *kyanol*. Zinin, in 1846, observed the formation of aniline from nitrobenzene by the agency of hydrogen gas, and called the substance *benzidam*. Erdmann and Hoffman then proved the identity of crystalline with kyanol, benzidam, and aniline. Coal-tar is a source of aniline, containing 0.3 to 0.5 per cent, but the principal source of aniline is nitrobenzene ($\text{C}_6\text{H}_5\text{NO}_2$), from which it is prepared in large quantities by the reducing action of nascent hydrogen, thus: $\text{C}_6\text{H}_5\text{NO}_2 + \text{H}_2 = \text{C}_6\text{H}_5\text{NH}_2 + 2\text{H}_2\text{O}$.

Preparation.—Aniline may be obtained on a small scale according to the process of Béchamp (*Amer. Jour. Pharm.*, 1862) as follows: Place 600 grains of iron filings and 500 grains of pure nitrobenzene into a quart tubulated retort,

which must be adapted to a receiver, and the receiver connected by a bent tube with a deep, small-necked flask, into which it reaches nearly to the bottom. The neck of the retort, the receiver, and the flask must be kept well refrigerated, and the flask must be left loosely stopped with cotton. Now gradually pour 500 grains of concentrated acetic acid through the tubulure of the retort, which should be closed and tied, being careful that the temperature does not rise too high. Reaction soon commences without the application of heat, and becomes rapid, with quick rise of temperature and rapid ebullition, and a large portion of the products will be lost should the refrigeration be imperfect. The spontaneous distillate that comes over, consists of aniline, acetate of aniline, and a little unchanged nitrobenzene. When the retort has cooled, these are returned to it from the receiver, and a careful sand-bath heat applied until the residue in the retort is dry. Now mix the distillate with an excess of liquor potassæ, which causes the aniline to separate and rise to the surface, whence it is to be removed and dried; it is sufficiently pure for medicinal purposes, and its amount is equal to about three-fourths of the nitrobenzene employed. Hydrochloric acid is now generally employed in place of acetic acid, and milk of lime instead of liquor potassæ. Aniline may also be readily procured by distilling a mixture of concentrated liquor potassæ and finely powdered indigo; the mass swells up greatly, and water holding ammonia in solution passes over, accompanied by aniline in the form of a brownish oil, which, when redistilled, furnishes pure aniline amounting to nearly one-fifth of the weight of the indigo.

Description.—Pure aniline is a nearly colorless, limpid liquid, having an oily appearance, but when impure or partly oxidized, as often met with in commerce, it varies in color from a dark to a light red. It is of an agreeable, vinous odor, and an aromatic, burning taste, and remains fluid at -20°C. (-4°F.). Its specific gravity is 1.020 to 1.028, and its boiling point 182.2°C. (360°F.). It is heavier than water, in which it is slightly soluble to the extent of 3 per cent; is soluble in alcohol, ether, wood spirit, acetone, aldehyde, carbon disulphide, and fixed and essential oils, and has little or no action on test papers, though it changes dahlia-blue to green. It refracts light powerfully, is a non-conductor of electricity, rapidly absorbs oxygen, even under water, and becomes converted into a brown, resinous mass. Camphor, many resins, phosphorus, and sulphur (if heat be employed) are dissolved by it. Commercial aniline (pure) contains about 1 per cent, and other grades more, of *toluidine*, i. e., *ortho* and *para amido toluene* ($\text{C}_6\text{H}_4\text{NH}_2$). It is a powerful base, forming mostly colorless, soluble salts, with a strong tendency to crystallize, and become rose colored; and decomposes the salts of iron, zinc, aluminum, mercury, copper, etc. In contact with chlorinated lime, or other hypochlorites it forms at once a deep violet-blue. Another color test for aniline is as follows: To aniline add sulphuric acid and a few drops of potassium chromate; a red color is developed, changing to deep-blue if aniline is present. It is chiefly employed for the production of various magnificent colors used in dyeing, and which are made by different processes (see below).

Action, Medical Uses, and Dosage.—Aniline is poisonous, though Wöhler and Frerichs state that it is harmless to dogs. It has been observed that workmen employed in preparing aniline are liable to intense bronchitis, with violent, dry, spasmodic cough, coinciding with ulcerations of the scrotum and inferior extremities; the ulcers being round, with distinct borders, often callous, and covered with thick, blackish crusts, beneath which is a dirty-gray base, with a neighboring painful tumefaction, and which cease with the cessation of the cause. According to M. Bergeron, those who are exposed to its vapors present a chloro-anemic appearance. In one case where a druggist was employed for two months in putting up packages of aniline, he was attacked with pulmonary catarrh, followed by prostration, tendency to syncope, occipital pains, dilatation of the pupils, and clonic convulsions of the extremities and muscles of the face; he was cured. According to Schuchardt and Demeyer, aniline belongs to the most violent poisons, and to that class which acts upon the nervous centers and the spinal marrow. The muscular contractions produced by it resembling electric shocks, the constant diminution of the sensibility, the paralytic state of the extremities, the acceleration of the respiration, and the activity of the heart, indicate this. It causes prickings of the parts with which it comes in contact,

and its elimination seems to be by the respiratory organs, not by the urine. One grain of aniline coagulates 4 grains of albumen, demonstrating its toxic influence upon the animal tissues. The workmen in it present a cadaveric blue appearance, the gums discolored, the lips bluish-gray, a slight paroxysm of cold, headache, and vertigo, which are not permanent, however. Cases of poisoning are on record from wearing clothes which have been dyed with aniline colors. Six drachms of aniline oil, taken with suicidal intent, produced death in a woman in a few hours. After death, aniline was found in the urine, and the lungs, kidneys, and heart-muscle showed nodular hemorrhagic effusions. It is practically useless as a remedy. Dose: 1 to 5 grains (see *Aniline Sulphate* below).

Derivatives, Aniline Colors, and Inks.—ANILINE CAMPHORATE has been introduced by Tomaselli (*P. J. Tr.*, 1887) as a remedy for *convulsive disorders*. The daily dose administered being from 8 to 12 grains.

ANILINI SULPHAS, Sulphate of aniline, Anilin sulphate.—Formula: $(C_6H_5.NH_2)_2.SO_4.H_2O$. Molecular Weight: 283.48. Dissolve 100 parts of aniline in 600 parts of alcohol (*U. S. P.*), to which add under constant stirring a freshly prepared mixture of 65 parts of pure, concentrated sulphuric acid, and 150 parts of alcohol. Allow the mixture to stand for a few hours in a dark place, then add under constant stirring about 400 parts of ether, transfer the magma of crystals on a funnel closed with a pellet of glass-wool, and displace the mother liquor by means of ether. Finally, dry the crystalline magma, without the aid of heat, by spreading it in thin layers on slabs of unglazed porcelain in a dark place. Avoid the use of filtering paper, and exclude bright daylight as much as possible (Hager). Sulphate of aniline forms small, crystalline, white plates or needles, without odor, if pure, but exposed to air and light acquires a reddish tint and an odor of aniline. It is soluble in water and diluted alcohol, much less soluble in strong alcohol, and insoluble in ether. Alkalies liberate from its aqueous solution an oily layer of its aniline, and the salt responds to the tests for sulphuric acid, as well as to all the tests for aniline. Sulphate of aniline has been used in *chorea* by Dr. Turnbull with success, and M. Filberti cured a case in four days, administering it in doses of 10 centigrammes twice a day, increasing it as much each day to prevent a relapse. He also cured a case of *epilepsy* by giving daily a solution of 5 centigrammes of aniline sulphate in 100 grammes of water, increasing the dose 5 centigrammes each day; in ten days the case was apparently cured. Others have also recommended it in these affections; while again it has been asserted that the sulphate of aniline has no influence upon the system. Its administration is apt to be followed by a blueness or yellowness of the skin, nails, and gums.

DIPHENYLAMINE.—Formula: $(C_6H_5)_2.NH$. Molecular Weight: 188.65. This substance may be obtained by heating aniline hydrochloride with aniline to a temperature of $240^\circ C.$ ($464^\circ F.$) in closed vessels, the following reaction taking place:

It is likewise formed when aniline is heated with phenol and zinc chloride ($ZnCl_2$) to a temperature of $260^\circ C.$ ($500^\circ F.$) (for description see No. 52 of *List of Reagents and Test Solutions*).

ANILINE COLORS.—Aniline (as such $C_6H_5.NH_2$) enters into the composition of but few of what are usually called aniline dyes. Most frequently used are its homologues, the toluidines, $(C_6H_4.CH_3.NH_2)$, its methyl derivatives, *e.g.*, mono- and di-methylaniline $(C_6H_4.NHCH_3)$ and $(C_6H_3.N[CH_3]_2)$, diphenylamine $([C_6H_5]_2.NH)$ and other amines. Many of the so-called aniline dyes as, *e.g.*, eosin, may not contain any aniline derivative at all, but have phenols as their principal constituent. Coal-tar dyes is a more comprehensive, and therefore more proper, name. The majority of these ever increasing dye-stuffs, may be classified broadly into two groups, according to whether they are derivatives of triphenylmethane $(CH:[C_6H_5]_3)$, or of azobenzene $(C_6H_5-N=N-C_6H_5)$. Oxy-triphenylmethane becomes a *chromogen* (a dye-forming principle), when the amido group (NH_2) , or the phenol group (OH) replaces hydrogen in the benzene ring. In the first case the color is produced when combining with an acid, in the second, with an alkali. Fuchsin, for example, is the hydrochloride of the (colorless) basis *rosaniline*, which has the following formula: $C(OH):(C_6H_4.NH_2)_2.C_6H_4.(CH_3)_2.NH_2$. Rosolic acid is similarly constituted, merely having OH in the place of NH_2 , being an anhydride of the compound: $(HO):C_6H_4.(OH)_2.(C_6H_4[CH_3]_2.OH)$. Alkalies produce the colored salts in the latter case. If in the case of rosaniline the hydrogen of the NH_2 group is replaced by methyl, the resultant product acquires a violet color (methyl violet), or if substituted by the benzene radical the product has a blue color (aniline blue). The *azobenzene* type likewise becomes a prolific chromogen upon the entrance of the amido group (NH_2) , or the phenol group (OH) in the benzene ring; in the first case we have basic dyes forming colored salts with acids; in the second, acid dyes, forming colored salts with alkalies. The simplest representative of this class of dyes, called *azo dyes*, is *aniline yellow*, the oxalate of (colorless) amido azobenzene $(C_6H_5-N=N-C_6H_4.NH_2)$. Another of the more simple azo dyes is *phenylene brown*, or *Vesuvine*, the hydrochloride of the following compound: $NH_2-C_6H_4-N=N-C_6H_4[NH_2]_2$. These azo dyes are formed by the action of nitrous acid upon aniline or other aromatic primary amines (both H atoms in the NH_2 group being intact), whereby the extremely unstable (and explosive) *diazo compounds* are formed; these react easily with aromatic amines, or phenols, azo compounds being the result. In the case of aniline yellow for example, the following reactions are involved: $C_6H_5.NH_2$ (aniline) + $NO_2Na + 2HCl = C_6H_5-N=N-Cl$ (*diazo-benzene-chloride*) + $2H_2O + NaCl$. $C_6H_5.N=N-Cl$ (*diazo-benzene-chloride*) + $C_6H_5.NH_2$ (aniline) = $C_6H_5.N=N-C_6H_5.NH_2$ (amido azobenzene, the basis of *aniline yellow*).

It is evident that when subjecting substituted amines to "diazotising," and afterwards allowing a variety of amines or phenols to react with the diazo compound formed, and enlarging upon all possibilities, an endless variety of azo dyes must be the result. The following aniline or coal-tar dyes may find special mention here:

ANILINE RED, Magenta, or Fuchsine, is a mixture of the hydrochlorides of rosaniline ($C_{20}H_{19}N_3$) and para-rosaniline ($C_{18}H_{17}N_3$) and is produced on a large scale by the oxidation of aniline (containing toluidine) with arsenic acid (Medlock and Girard), or with nitrobenzene (Couper). It is stated that fuchsine obtained by the arsenic acid process, is liable to contain arsenic; this dangerous impurity is said to be removable by recrystallization. The acetate of rosaniline is usually called **ROSEIN**; the nitrate is called **AZALINE**. The latter was formerly prepared by oxidizing aniline oil with mercuric nitrate.

FUCHSINE, the hydrochloride, forms crystals of a green, metallic lustre, in reflected light. It is soluble in 10 parts of alcohol, and 300 parts of water. On account of its insolubility in pure volatile oils, it is employed to detect the presence of alcohol in them. It is also employed as a valuable staining material in bacteriology, and in botany for staining lignified cell-walls (Bastin). Fuchsine is sometimes used to color wines, and though apparently of use in *tubular nephritis* and *scarlatinal dropsy*, its position as a remedy is as yet by no means well established. The dose is from $\frac{1}{4}$ to 4 grains 3 or 4 times a day.

HOFMANN'S VIOLET, METHYL VIOLET.—*Hofman's violet* is obtained by the action of methyl or ethyl chloride, or iodide, upon rosaniline salts, whereby three H atoms of the NH_2 groups are substituted by the methyl or ethyl group. The violet tint becomes more bluish the more hydrogen atoms are substituted.

METHYL VIOLET, in its purest form, is a salt of penta-methyl rosaniline, the commercial grade also containing hexa-methyl rosaniline. It is prepared by oxidizing dimethyl-aniline with copper chloride. When acted upon by methyl chloride or methyl iodide, it forms addition products, the zinc double chlorides of which are called **METHYL GREEN**, or **IODINE GREEN**, respectively.

PYOKTANIN, related to methyl violet, was introduced in 1890, into medical practice, for general surgical purposes; it was claimed that it retarded the growth of bacteria and bacilli in a solution of 1 to 30000, and prevented putrefaction in a solution of 1 to 1000 (*Amer. Jour. Pharm.*, 1890). There are two pyoktanins in the market, a blue pyoktanin (*pyoktanin caeruleum*), probably tetra-penta- and hexa-methyl violet, and a yellow pyoktanin (*pyoktanin aureum*), intended for ophthalmic practice, probably belonging to the auramines (diphenyl-amine derivatives).

Pyoktanin was introduced into medicine by Prof. J. Stilling, of Strasburg. Hypodermatically, it is said to relieve *rheumatic* and *neuralgic* pains. To the conjunctiva it is a mild topical anæsthetic. It is employed in powder (with talc), and in pencils. Wounds, ulcers, carbuncles, *buboes*, *boils*, etc., as well as *gonorrhœa* and *chronic cystitis* have been successfully treated with it. In various eye and ear troubles it has also been used by some with apparently good results, while others condemn it severely, attributing much harm to its use, as well as claiming injury from its staining properties. The stains of pyoktanin may be removed by alcohol or diluted nitric or hydrochloric acids. Very likely some of its deleterious effects may be attributed to impurities.

ANILINE BLUE is the salt of triphenyl para-rosaniline $HOC:(C_6H_4NH[C_6H_5])_3$, and is obtained by boiling together a rosaniline salt with an excess of aniline.

MALACHITE GREEN is the oxalate or zinc double chloride of tetra-methyl-diamido-triphenyl carbinol, $(C_6H_5.C[OH]:C_6H_4.N[CH_3])_3$, and is obtained by heating benzaldehyde with dimethyl aniline and zinc chloride or oxalic acid, and acting upon the product with oxidizers.

AURIN, PARAROSOLIC ACID, CORALLIN YELLOW ($C_{19}H_{14}O_3$), is the lower homologue of rosolic acid, and is prepared by heating phenol with oxalic and sulphuric acids. It forms red needles or prisms of metallic luster, is soluble in hydrochloric and acetic acids and alcohol, and dissolves in alkalis with a deep-red color, forming salts therewith. (See *Corallin Test Solution*).

CORALLIN RED (Pæonin), is an intermediary product between para-rosaniline, and aurin, containing one or two amido groups besides the remaining phenol groups.

ROSOLIC ACID ($C_{20}H_{16}O_3$), one of the indicators directed by the U. S. P. (see *Rosolic Acid Test Solution*), may be obtained from rosaniline by "diazotizing" and boiling with water, which has the effect of replacing the NH_2 group by the OH group. It may also be prepared in a way analogous to that in which rosaniline is made, viz., by oxidizing a mixture of phenol and cresol ($C_6H_4[CH_3]OH$) with arsenic and sulphuric acids.

PHTALEINES. These are also phenol derivatives of triphenyl-methane, and are obtained by heating phthalic anhydride (1 Mol.) with phenols (2 Mols.), in the presence of sulphuric acid, oxalic acid, or stannic chloride.

PHENOLPHTHALEIN is formed by treating phthalic anhydride with phenol and stannic chloride. Its formula is: $C_{20}H_{14}O_4 = C_6H_4.(CO.O).C:(C_6H_4OH)_2$. It is a yellow powder, soluble in alcohol, the solution forming an intense red with alkalis. It is directed by the U. S. P. as an important indicator in alkalimetry (see *Phenolphthalein Test Solution*).

FLUORESCEN. This substance is prepared by heating phthalic anhydride (5 parts), with resorcin (7 parts), to $200^\circ C$. ($392^\circ F.$); for reasons of analogy it may therefore be called resorcin-phthalein. Its composition is: $C_{20}H_{12}O_4 + H_2O = C_6H_4.(CO.O).C:(C_6H_3[OH]_2)_2$.

EOSINS are the alkali salts of halogen substitution products of fluorescein; *eosin yellow*, for example, is the salt of tetra-brom fluorescein, and *eosin blue* is that of tetra iodo-fluorescein. Fluorescein and eosin are among the indicators directed by the U. S. P. (see *Indicators*).

METHYL ORANGE is an azo dye, which occurs under the names of *Helianthin*, *Orange III*, *Poirrier's Orange 3P*, and *Tropæolin D*. Its formula is $SO_3H.C_6H_4-N=N-C_6H_4N(CH_3)_2$, from

which it is evident (see introductory remarks) that it is prepared from sulphanilic acid and dimethyl aniline. In water and alkalies it dissolves with a light-yellow color, which turns red with acids. For its use as an indicator see *Methyl-orange Test Solution*.

METHYLENE BLUE, Tetramethyl thionin chloride ($C_{16}H_{18}N_3SCl$). This must not be confused with aniline blue, a trisulphonate of which is called *methyl blue*, which belongs to the tri-phenyl-methane group, while methylene blue belongs to an entirely different group. It is produced by treating an acid solution of dimethyl para-phenylene diamine ($NH_2 \cdot C_6H_4 \cdot N(CH_3)_2$), with hydrogen sulphide and ferric chloride. The blue solution is then precipitated with $NaCl$ and $ZnCl_2$. Methylene blue occurs in scale-like blue crystals having a bronze tint, and being easily soluble in water. The formation of this substance is utilized as a delicate test for hydrogen sulphide (E. Fischer and Bernthsen).

Methylene blue is used in the arts as a dye-stuff. Medicinally, it has been employed as an antipyretic, anodyne, and antiperiodic. *Rheumatism, gonorrhoea, cystitis, pyelitis, and malaria*, have been treated with it. It has also been employed in the treatment of *cancer*. The internal dose is 2 to 4 grains in capsules; as an injection, 1 grain in solution.

Prof. F. J. Locke reports success with this agent in *old tibial ulcers*. His method is to dissolve 20 grains of methylene blue in 1 fluid ounce of water, and with this solution paint the ulcers night and morning, keeping the parts covered with a cloth wetted with a 1 to 1000 corrosive sublimate solution. After each treatment the limb should be covered with an elastic bandage.

ANILINE BLACK, Jetoline. Its formula is a multiple of C_6H_5N , perhaps $C_{12}H_{11}N_3 \cdot HCl$ (Liechti). It is produced on the fiber direct by slow oxidation of aniline by means of potassium chlorate and copper chloride, or hydrochloric acid and potassium bichromate (*Amer. Jour. Pharm.*, 1880), or more recently with ammonium vanadate. The resulting dark-green color appears black.

ANILINE INKS. *Aniline inks* are prepared by dissolving 15 parts of dry aniline dyes (either red, blue, green, or yellow), in 150 parts of strong alcohol and 1000 parts of distilled water, in a porcelain-lined vessel by the aid of a gentle heat, until the odor of alcohol is dissipated, and adding a solution of 60 parts of gum arabic in 250 parts of water (*Amer. Jour. Pharm.*, 1868, p. 332). An *indelible ink* may be made with aniline black as follows: 1, dissolve crystallized chloride of copper 17½ parts, chlorate of sodium 22½ parts, and chloride of ammonium 11½ parts, in distilled water 125 parts; 2, dissolve chlorohydrate of aniline 2 parts, in distilled water 3 parts, and add to it of a solution of 1 part gum arabic to 2 parts of water, 2 parts, and glycerin 1 part. Mix 4 parts of No. 2 with 1 part of No. 1, as wanted. It forms a greenish liquid, which may be applied with pen, pencil, or brush. As it changes in a few days, it should be mixed only as wanted (*Ibid.*, p. 335).

STAMPING INK. Dissolve any aniline dye 5 parts, in hot water 75 parts; add syrup 1 part, and glycerin 2 parts.

ANISUM (U. S. P.)—ANISE.

"The fruit of *Pimpinella Anisum*, Linné"—(U. S. P.). (*Anisum vulgare*, Moench). *Nat. Ord.*—Umbelliferae.

COMMON NAMES: *Aniseed, Anise.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 122.

Botanical Source.—Anise has a perennial, spindle-shaped, ligneous root, and smooth, erect, branched stem, 10 or 12 inches in height. The leaves are petioled; the radical ones roundish, heart-shaped, lobed, and cut serrated; the cauline ones biternate, with linear-lanceolate, rather cuneate-acuminate segments. The flowers are small and white, and borne in umbels on long stalks, and are 9 or 10-rayed, and naked; the partial ones have a few subulate, reflexed bracts. Calyx wanting or minute; corolla of 5 obovate, emarginate petals, with an inflexed lobe. Stamens 5, longer than the petals. The anthers are roundish, the styles subulate, spreading, long, and capitate. The fruit is ovate, 1½ lines long, dull-brown, slightly downy, not at all shining; half-fruits or mericarps with 5 filiform, equidistant, elevated ridges, sometimes rather wavy, and paler than the channels. The commissure is broad and flat (L.).

History.—Anise originally came from Egypt, and is at present cultivated in many of the warm countries of Europe; the fruit of the Spanish plant is that which is more generally selected for medical purposes. The fruit, popularly called *aniseed*, is the official portion. Care must be taken not to confound any of the seed of the poisonous umbelliferous plants, as of the *Conium maculatum*, with those of the anise; a little attention will detect any accidental admixture of this kind, as the differences in the seed are well marked. The odor of anise is penetrating, and fragrant, and the taste aromatic and sweetish (P.). Water partially takes up its properties, alcohol wholly so; these are due to a volatile oil which may be procured by distillation of the fruit with water.

Description.—"About 4 or 5 Mm. ($\frac{1}{4}$ to $\frac{1}{2}$ inch) long, ovate, compressed at the sides, grayish, finely hairy, and consisting of 2 mericarps, each with a flat face, and 5 light-brownish, fliform ridges, and about 15 thin oil-tubes, which can be seen

Fig. 35.

Pimpinella Anisum.

in a transverse section by the microscope. It has an agreeable, aromatic odor, and a sweet, spicy taste. It may be distinguished from conium fruit (which it somewhat resembles, and which has been mistaken for it), by the odor and taste, and by the conium fruit consisting usually of single mericarps, which are smooth, grooved upon the face, and have crenate ridges with wrinkles between them, and no oil-tubes"—(U.S.P.).

Chemical Composition.—A volatile oil is contained in the external coat of the seeds, while a green-colored, fat oil of a butyraceous consistency, is obtained by expression of their inclosed substance. Brandes obtained from the fruit of anise, concrete fixed oil, green fat oil, resin, nitrogenous matter, sugar, gum, bimalate and binacetate of calcium, bimalate of potassium, volatile oil, lignin, silicate of iron, water, gum-resin, phosphate of calcium, extractive with various salts, etc.

The star-anise of cordial manufacturers possesses a taste and odor similar to the anise, but is procured from the *Illicium Anisatum*, Loureiro, a plant growing in Eastern Asia. A volatile oil is obtained by distillation from its fruit, which is often fraudulently substituted for the oil of anise; it is called *oleum badiani* or *oil of star anise*. Oil of common anise is sometimes adulterated with spermaceti or camphor, to promote its solidification; the former may be known by its insolubility in cold alcohol, the latter by its odor.

Oil of anise yields, upon oxidation, *anisic acid* ($C_6H_5O_3 = C_6H_4[OCH_3]COOH$). This acid occurs in the form of colorless crystals, insoluble in water, but freely soluble in alcohol. It is an oxidation product of *anethol* ($C_{10}H_{12}O$) (the chief principle of the oils of anise [94 per cent, Flückiger], star anise and fennel), obtained by fractional distillation of the oil of anise, reserving and purifying that fraction distilling from 230° to 234° C. (446° to 453.2° F.).

Action, Medical Uses, and Dosage.—A stimulant and carminative; used in cases of *flatulency*, *flatulent colic of infants*, and to remove *nausea*. Sometimes added to other medicines to improve their flavor, correct griping and other disagreeable effects. The dose of aniseed, crushed or powdered, is from 20 to 40 grains. Infusion (ʒij or ʒiij to aqua Oss.), for infants, in doses of a teaspoonful.

Derivatives.—ANISIC ACID is claimed to be antipyretic and antiseptic, acting very much like salicylic acid, and has been employed with reputed success in *articular rheumatism*, and as a topical application to *wounds*. For internal use *sodium anisate* is preferred, the acid being but little used. Dose of the salt, 15 grains.

ANTENNARIA.—PEARLY EVERLASTING.

The leaves of the *Antennaria margaritacea*, Robert Brown; (*Gnaphalium margaritaceum*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Pearly everlasting*, *Pearl-flowered life everlasting*.

Botanical Source.—*Antennaria margaritacea* is a perennial plant, with a simple, erect stem, corymbosely branched above. The leaves are linear-lanceolate, acute, 3-veined, sessile, and beneath the stem woolly; the corymbs are many-flowered and fastigate; the scales of the hemispheric involucre are elliptic, obtuse, opaque, pearl-white, the outer ones only tomentose at the base; heads dicecious; the pistillate flowers are very slender; pappus simple, bristly, capillary in the fertile flowers, and in the sterile club-shaped, or barbellate at the summit. The corolla is yellowish (W. G.).

History and Chemical Composition.—The name *Antennaria* is from the resemblance of the sterile pappus to the *antennæ* of many insects (W.). The plant is slightly fragrant, and grows in dry hills and woods of various parts of the United States; it is from 1 to 2 feet in height, and bears yellow and white

flowers in July. The leaves are the parts used. They contain a bitter principle and an essential oil.

Action, Medical Uses, and Dosage.—Anodyne, astringent, and pectoral. A decoction has proved beneficial in *diarrhœa* and *dysentery*, and in *pulmonary affections*. Externally, it forms an excellent poultice in *sprains*, *bruises*, *boils*, *painful swellings*, etc., and is said to produce sleep when applied externally to the head, even in cases where a poultice of hops has failed. Rafinesque is authority for the statement that the Indians, for a trifle, would allow rattlesnakes to bite them, to show that they could cure the bite at once with this plant. Decoction (3j to aqua Oj) freely.

Related Species.—*Antennaria plantaginifolia*, Robert Brown. (*Gnaphalium plantaginifolium*, Linné; *G. plantagineum*, Pursh; *G. dioicum*, var. *plantaginifolium*, Michaux). *Plantain life everlasting*. *Cudweed*. *Mouse-ear everlasting*. Canada and the United States, in open woods and barren hills. Domestic remedy, when boiled in milk, for *diarrhœa* and *dysentery*. Reputed efficacious in bites of *poisonous reptiles*.

Antennaria dioica, Gærtner (*Gnaphalium dioicum*, Linné). Europe. Used the same as preceding species.

Antennaria arenarium, Linné. Europe and Asia. Uses same as preceding species.

Gnaphalium polycepalum, Linné. (See *Gnaphalium*).

ANTHEMIS (U. S. P.)—ANTHEMIS.

"The flower-heads of *Anthemis nobilis*, Linné, collected from cultivated plants"—(U. S. P.).

Nat. Ord.—Compositæ.

COMMON NAMES AND SYNONYMS: *Chamomile*, *Roman chamomile*, *Anthemidis flores*, *English chamomile*, *Flores chamomillæ Romanæ*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 154.

Botanical Source.—This is a perennial herb, with a strong root, having long fibers. The stems, in a wild state, are prostrate, but more upright when cultivated in gardens. They are about a span long, round, hollow, furrowed, downy, leafy, and branched. The leaves are doubly pinnate, sessile, and pale-green in color, having small, thread-shaped leaflets, which are rather flat or channeled above, convex beneath, somewhat downy, acute, and commonly trilobed. The flower-heads are terminal and solitary, with ligulate, white, ray-florets, and a yellow center of tubular florets.

History and Chemical Composition.—Chamomile is indigenous to Southern Europe, where it is cultivated for the purposes of medicine, and gathered and quickly dried by artificial heat. There are two varieties, the single and the double, of which the former is the best, the latter being commonly the result of cultivation. The white flowers are the best; they have an aromatic, agreeably bitter taste, a strong and peculiar odor, and yield by distillation 0.45 per cent of a volatile oil of a pale-blue color at first, but gradually becoming brownish or yellowish (*Oleum Anthemidis*). Their aromatic and stimulant properties are due to this oil and a resin; their tonic to bitter extractive and tannic acid. They also contain chlorophyll, albumen, extractive, gum, salts, fat, and glucose. Camboulises (1871) obtained *quercitrin*, a yellow, coloring matter, when boiling the ether extract of the drug with water, and allowing it to cool. The filtrate yielded to ether a crystallizable, bitter principle, which Camboulises thought identical with anthemic acid, supposed to have been obtained by Pattone in 1859 from *Anthemis arvensis*. No alkaloid was found in the drug. A fixed oil may be obtained from the seeds by expression. The flowers yield their properties to water or alcohol. The wild flowers are seldom met with in commerce, and the darker grades of flowers, probably gathered in bad weather, bring a lower price.

Description.—The flower-heads are rather larger than a daisy, with a convex, yellow disk and numerous white, spreading, or reflexed rays. The involucre has small, shining, membranous-bordered scales, rather downy. The receptacle is

Fig. 26.

Anthemis nobilis.

obtusely conical, with minute, chaffy scales, which do not appear until the disk-florets are turned to one side; the innermost are gradually narrowest. The ray-florets are white, strap-shaped, and tridentate; about eighteen in number when wild (usually in a single row), but when cultivated may be more numerous, the disk-florets often taking on a ligulate form and becoming white. The disk-florets are yellow, many, tubular, and consist of five segments. The stamens are five in number, the ovary obovate, the style slender, and the stigma two-cleft and reflexed. The ovate seeds are flat.

The flowers directed by the Pharmacopœia are those of the cultivated plant, and are thus described in that work: "Heads subglobular, about 2 centimeters ($\frac{3}{4}$ inch) broad, consisting of an imbricated involucre, and numerous white, strap-shaped, three-toothed florets, and few or no yellow, tubular disk-florets, inserted upon a chaffy, conical, solid receptacle. It has a strong, agreeable odor, and an aromatic, bitter taste"—(U. S. P.).

Admixtures.—The flower-heads of *Matricaria Chamomilla*, Linné (German chamomile); *Maruta Cotula*, DeCandolle (Mayweed); *Achillea Ptarmica*, Linné (Sneezewort); *Pyrethrum Parthenium*, Linné (Feverfew); *Anthemis arvensis*, Linné (Corn chamomile), and of other species of compositæ are sometimes admixed with chamomile flowers as adulterants. The double flowers of Roman chamomile (*Anthemis nobilis*) may be determined from the double flowers of Feverfew (*Pyrethrum Parthenium*) by the following characters: *A. nobilis* flowers have a peculiar and pleasantly aromatic odor; the involucre is nearly flat, and composed of a number of spreading, nearly equal, overlapping bracts, with broadly and evidently membranous margins; when the florets are removed, the receptacle is observed to be a solid, conical body, more or less pointed at the apex, and the scales on it are thin, concave, blunt-pointed, or obtuse, more numerous, more closely compacted, and more membranous than those of *P. Parthenium*. The flowers of *P. Parthenium* are less double than those of *A. nobilis*, have a strong, peculiar, and more or less unpleasant odor; the involucre is convex, and composed of a number of nearly equal, imbricated, concave bracts, which are bent inward above, and each having a prominent ridge on its dorsal surface; when the florets are removed the receptacle is observed to be slightly convex or nearly flat, and rounded above, and the scales on it are lanceolate, acute-pointed, less in number than those of *A. nobilis*, and less membranous.

The Common, or Wild chamomile, German chamomile (*Matricaria Chamomilla*), is usually with single flowers, which have a strong, peculiar, unpleasant odor, a convex involucre, composed of nearly equal, obtuse-pointed bracts, not distinctly membranous at their margins, and the receptacle is hollow, broadly conical, or nearly cylindrical in shape, naked, or without any scales.

The flowers of the *Achillea Ptarmica* have rounder rays, much shorter than those of *A. nobilis*, and are odorless, but have a harsh, acrid taste.

Maruta Cotula may be known by its disagreeable odor, which differs from that of chamomile, while the *Anthemis arvensis* is without odor. The former has an almost cylindrical receptacle, studded with slender, permanent scales.

Action, Medical Uses, and Dosage.—In doses of from $\frac{1}{2}$ drachm to 2 drachms of the flowers, or from 1 to 3 fluid ounces of their infusion (3ss to aqua Oj), chamomile is a tonic; from 5 to 12 fluid ounces of a warm, strong infusion usually vomits. The cold infusion has proved useful in *dyspepsia*, *weak digestion*, and in all cases of *weak or irritable stomach*, as well as in obstinate *gastro-intestinal irritation*; also in *intermittent* and *typhus*. The oil is carminative and antispasmodic. Used in *flatulency*, *colic*, *cramp in the stomach*, *hysteria*, *nervous diseases*, and *painful dysmenorrhœa*. Colds, when due to sudden checking of the cutaneous secretions, are quickly relieved by anthemis, as are also recent cases of *rheumatism* and *neuralgia*, brought on in the same manner. In *amenorrhœa* from cold immerse the feet in mustard water, and after putting the woman to bed, give freely of the warm infusion. Dose of the oil, 5 to 15 drops on sugar; specific anthemis, 1 to 5 drops. The flowers of the *Matricaria Chamomilla* (see *Matricaria*) possess similar properties to the anthemis. A poultice of chamomile flowers is said to prevent *gangrene* and to remove it when present.

Specific Indications and Uses.—Gastro-intestinal debility; flatus; dysmenorrhœa from cold; malarial affections. A tonic and antispasmodic.

ANTIMONII ET POTASSII TARTRAS (U. S. P.)—**ANTIMONY AND POTASSIUM TARTRATE.**

FORMULA: $2K(SbO)C_4H_4O_6 + H_2O$. MOLECULAR WEIGHT: 662.42.

SYNONYMS: *Tartar emetic*, *Tartarated antimony*, *Antimonium tartaratum*, *Antimonium tartarizatum* (*Tartarizatum*), *Antimonii potassio-tartras*, *Tartarized antimony*, *Tartarus emeticus*.

"Antimony and potassium tartrate should be kept in well-stoppered bottles"—(U. S. P.).

History and Preparation.—Mynsicht, in 1631, prepared this salt from crocus of antimony (saffron of antimony) and cream of tartar (potassium bitartrate); Glauber, in 1648, employed cream of tartar and flowers of antimony. This preparation is made in various ways, the readiest of which is to boil together 4 parts of oxide of antimony and 5 parts of bitartrate of potassium, both in fine powders, previously mixed, in 36 parts of distilled water; filter the liquid, concentrate, and crystallize by slow cooling. These proportions are the same as directed in the U. S. P. (1870), but boiling water was directed, into which the mixed powders were to be introduced and boiled for 1 hour.

The *British Pharmacopœia* directs: "Take of oxide of antimony, 5 ounces (av.); acid tartrate of potassium, in fine powder, 6 ounces (av.); distilled water, 2 pints (*Imp.*). Mix the oxide of antimony and acid tartrate of potassium with sufficient distilled water to form a paste, and set aside for 24 hours. Then add the remainder of the water, and boil for a quarter of an hour, stirring frequently. Filter and set aside the clear filtrate to crystallize. Pour off the mother liquor, evaporate to one-third, and set aside that more crystals may form. Dry the crystals on filtering paper at the temperature of the air"—(*Brit. Phar.*).

Whatever process is pursued, it is essential that the antimony oxide be slightly in excess that crystals of free cream of tartar be not deposited with the tartar emetic. The British process obviates long boiling, which tends to prevent the formation of an uncrystallizable portion, and the coloring of the crystals necessitating recrystallization. The antimonious oxide should be wholly free from oxychloride, and the cream of tartar free from calcium tartrate, the latter necessitating recrystallization and the former partially preventing crystallization, on account of rendering the solutions acid. Some manufacturers use an impure antimonous oxide, having methods by which they can purify the product to advantage, but the producer on a small scale should rely upon pure materials. The oxychloride was used instead of the oxide by Berzelius and Henry. In London, antimony ash is largely employed in manufactories for the preparation of this salt.

The reaction in preparing this salt is as follows: $Sb_2O_3 + 2KHC_4H_4O_6 = 2(K[SbO]C_4H_4O_6) + H_2O$, the hydrogen being displaced by the radical *antimonyl* (SbO), which is univalent.

Description.—"Colorless, transparent crystals of the rhombic system, becoming opaque and white on exposure to air; or a white, granular powder, without odor, and having a sweet, afterwards disagreeable, metallic taste. Soluble in 17 parts of water at $15^\circ C.$ ($59^\circ F.$), and in 3 parts of boiling water, but insoluble in alcohol, which precipitates it from its aqueous solution in the form of a crystalline powder. When heated to $110^\circ C.$ ($230^\circ F.$), the salt loses its water of crystallization (2.71 per cent). When heated to redness, it chars, emits an odor resembling that of burning sugar, and leaves a blackened residue having an alkaline reaction. The aqueous solution of the salt possesses a slightly acid reaction, and yields, with hydrochloric acid, a white precipitate soluble in an excess of the acid; but no precipitate occurs if tartaric acid had previously been added"—(U. S. P.).

If tartar emetic be prepared from the oxychloride, tetrahedral crystals form. Wine and proof-spirit dissolve the salt, which, as met with in commerce, is usually powdered. Its solution in water is unstable, but decomposition may be prevented by adding one-fifth part of alcohol. Tartar emetic is incompatible with the concentrated and diluted acids, alkalies, most metals and their carbonates, hydrosulphides, soaps, gallic and tannic acids, and most astringent, bitter

bodies, as Peruvian bark, rhubarb, etc. These latter render it weaker in quality, while galls render it quite inert.

Tests.—"In a solution of the salt, acidulated with hydrochloric acid, hydrogen sulphide T.S. produces an orange-red precipitate. The aqueous solution, even when largely diluted, at once becomes permanently turbid on the addition of a small quantity of potassium carbonate or calcium hydrate T.S. A 1 per cent aqueous solution of the salt, acidulated with acetic acid, should not be affected by the addition of a few drops of barium chloride T.S. (absence of sulphate), silver nitrate T.S. (chloride), ammonium oxalate T.S. (calcium), or potassium ferrocyanide T.S. (iron and other metals). On adding sodium carbonate T.S. to crushed crystals of the salt, effervescence should not ensue (absence of potassium bitartrate). If 1 Gm. of the salt be dissolved, with the aid of heat, in hydrochloric acid, and to this solution 1 Cc. of stannous chloride T.S. be added (see *List of Reagents*, Bettendorff's Test for Arsenic), together with a small piece of pure tin-foil, no turbidity or coloration should ensue within 1 hour (limit of arsenic). If 0.331 Gm. of the crystallized salt, or 0.322 Gm. of the salt dried at 110° C. (230° F.), be dissolved in 10 Cc. of water and about 20 Cc. of a cold, saturated solution of sodium bicarbonate and a little starch T.S. added, it should require not less than 20 Cc. of decinormal iodine V.S. to produce a permanent blue color (corresponding to 100 per cent of the pure salt)"—(*U. S. P.*).

Potassium sulphate, to the extent of from 40 to 70 per cent, was found in commercial tartar emetic by A. H. Jackson—(*Year Book of Pharm.*, 1885).

Action and Toxicology.—Applied to the skin, a strong solution or ointment of tartar emetic produces a pustulous eruption of a peculiar character, accompanied with a more or less intense inflammation. The pustules resemble those of variola, and when the scab drops an indelible cicatrix remains. Internally, oft-repeated, small amounts ($\frac{1}{16}$ to $\frac{1}{10}$ grain) produce an uncomfortable feeling, with nausea, colic, diarrhoea, anorexia, debility, pasty tongue, and possibly an eruption of pustules. Emetic doses occasion nausea, a sensation of sinking, free pyalism, violent and protracted retching and vomiting, with cold extremities, and a cool, perspiring skin. If given with plenty of fluid, purgation, may result instead of emesis. Taken internally, in large quantities, tartar emetic acts as a violent poison, and may produce a very lively inflammation of the intestinal canal, as manifested by excessive vomiting, hypercatharsis, tenesmus, great heat and pain in the gastric region, colicky symptoms, oppressed breathing, cold surface, and gradual loss of the senses and vital powers. The antidotes are infusions of *Geranium maculatum*, table tea, solution of tannic acid, or other vegetable astringent and mucilaginous infusions, aided by preparations of opium to check the excessive evacuations; together with the usual means for combating inflammatory symptoms. Alcohol and digitalis may be required to support the heart. The quantity sufficient to kill is small. A child was killed by $\frac{1}{2}$ of a grain; an adult by 2 grains, but circumstances favored the accident; 15 grains killed a young man in 6 hours. On the other hand, recovery has taken place after a teaspoonful had been taken. Enteritis and loss of hair were the secondary results (see Taylor, *Med. Juris.*).

Medical Uses and Dosage.—Tartar emetic was formerly much used as an emetic in doses of from 1 to 4 grains, dissolved in a tumblerful of warm water, of which 1 or 2 tablespoonfuls were to be given every 5 or 10 minutes, until vomiting was produced, aiding its operation by frequent draughts of warm water. It has likewise been employed as a nauseant and diaphoretic in *febrile* and *inflammatory diseases*, especially of the thoracic organs; the dose varying from $\frac{1}{4}$ of a grain to 1 grain, every 1, 2, or 4 hours. One or 2 grains in a pint or two of water will generally act as a purgative. In doses of 4 grains, gradually increased to 20 or even 40 grains during the 24 hours, Rasori, Laennec, Balfour, and others have considered it very useful in acute inflammations, as *pneumonia*, *hepatitis*, *jaundice*, etc. It was thus said to exert a sedative or contra-stimulant effect, and could only be advantageously administered in this way, provided the first doses did not produce vomiting nor superpurgation, and the stomach become in that state termed *tolerance*. A prominent old-school writer, the therapeutic editor of the *National Dispensatory*, has justly characterized the mischief done by tartar emetic, used as an emeto-cathartic, as "one of the medical scandals of the sixteenth century,"

and hoped that the tendency toward its revival, as was manifested a few years since (1882-7-8), would be checked by those who were acquainted with "its martyrology." It will be remembered that the abuse (not the use) of this agent was one of the potent factors in bringing into existence the Eclectic School of Medicine. The use of tartar emetic in the Eclectic School has been very limited. It never has been employed in the same manner as by the old school, and never as an emetic. The only field of action thus far determined for it has been in *broncho-pulmonary disorders* of a sub-acute character, particularly in *sub-acute inflammation of the bronchioles*. "The simplest indication," says Prof. Scudder (*Spec. Med.*), "for the minute dose of this remedy is increased secretion of the respiratory mucous membrane. To this may be added a feeble pulse, pallid skin, cool extremities, cold sweats, uneasiness in the lower abdomen, and frequent desire to go to stool and urinate. If we were giving it in the old-fashioned dose, the indications would be the reverse of this." Its usefulness in *capillary bronchitis* is marked. The increased secretion, with lack of power to expectorate, the rattling cough, persisting until the sputa is finally dislodged, and attended with a sense of faintness, difficult, suffocative breathing, wheezing, and loudly subcrepitant, bronchial *rales* are the guides to its use. Add to these a pallid surface, bathed in a cold, clammy sweat, a cyanotic countenance, with frequent urgings to empty the bowels and bladder, and hypogastric uneasiness, and it is the remedy for this unpleasantness, and when indicated by the whole or a portion of these symptoms, and particularly by the free secretion, with lack of power to dislodge the sputa, the act being feeble and attended with faintness, it should be remembered in *asthma*, *crup*, *pneumonia*, *bronchitis*, and *bronchorrhœa*. It is particularly valuable in the *bronchial catarrh* of the young and of the enfeebled and debilitated old.

Some practitioners pretend to have cured many chronic diseases by the administration of minute doses of tartar emetic, repeated 3 or 4 times daily. It was formerly often used in the form of lotion, liniment, ointment, or plaster, as a counter-irritant in many painful, deep-seated, and chronic maladies. A drachm of tartar emetic to 4 drachms of lard for an ointment, or, dissolved in $1\frac{1}{2}$ fluid ounces of water as a wash. Not unfrequently the external application of tartar emetic gives rise to *obstinate ulcers*, sometimes of a gangrenous character, and in some cases severe and fatal constitutional disorder has resulted.

It must be borne in mind that to accomplish specific results with this agent, the dose must be minute. It is generally preferred in homœopathic trituration—2x trituration for adults; 3x trituration for children—of which about 2 grains should be given every 2 hours.

Specific Indications and Uses.—Sub-acute bronchial inflammation; cough, rattling (sometimes hollow and reverberating), with loud, fine, subcrepitant *rales*; hoarseness, with tenderness of the larynx; capillary bronchitis; feeble cough of the aged, with free secretion and lack of power to expectorate.

ANTIMONII OXIDUM (U. S. P.)—ANTIMONY OXIDE.

FORMULA: Sb_2O_3 . **MOLECULAR WEIGHT:** 287.08.

SYNONYMS: *Antimony trioxide*, *Antimonous oxide*, *Oxydum stibicum*, *Oxydum antimonicum*, *Stibium oxydatum*.

History.—Under the name *Flores antimonii* (*flowers of antimony*, or the *Argentine flowers of antimony*), this substance was known to the alchemists since the time of Basil Valentine. It was first procured by roasting the sulphide, but afterward by burning metallic antimony in the air. This oxide constitutes *white antimony* or the ore known as *valentinite*; a compound consisting of this oxide and antimonious oxide forms *cervantite* or *antimony ochre*. A large deposit of this ore is also to be found in the district of Sonora, Mexico (*Amer. Jour. Pharm.*, 1881). Antimony oxide is mostly used as a substitute for white lead in painting.

Preparation.—"Take of solution of chloride of antimony, 16 fluid ounces; carbonate of sodium, 6 ounces (av.); water, 2 gallons (Imp.); distilled water, a sufficiency. Pour the antimonial solution into the water, mix thoroughly, let the precipitate settle, remove the supernatant liquid by a siphon, add 1 gallon of distilled water, agitate well, let the precipitate subside, again withdraw the fluid,

and repeat the processes of affusion of distilled water, agitation, and subsidence. Add now the carbonate of sodium previously dissolved in 2 pints of distilled water, leave them in contact for half an hour, stirring frequently; collect the deposit on a calico filter, and wash with boiling distilled water until the washings cease to give a precipitate with a solution of nitrate of silver acidulated by nitric acid. Lastly, dry the product at a temperature not exceeding 100° C. (212° F.)"—(*Br. Ph.*).

The *U. S. P.* (1870) process differed from the above chiefly in the agents employed, the chloride being first prepared by digesting 4 parts of black sulphide of antimony and 18 parts of hydrochloric acid: $\text{Sb}_2\text{S}_3 + 6\text{HCl} = 2\text{SbCl}_3 + 3\text{H}_2\text{S}$. The hydrogen sulphide escapes for the most part, while the antimonous chloride remains in solution. The use of nitric acid was also directed in the *U. S. P.* process, the object being to oxidize what little hydrogen sulphide would remain in the liquid. The aqueous solution of antimony terchloride thus formed is now diluted, whereby antimonous oxychloride ($2\text{SbCl}_3 \cdot 5\text{Sb}_2\text{O}_3$), or *powder of Algaroth*, is precipitated. This, when washed with water, is deprived of a portion of its chlorine combined as hydrochloric acid, leaving a still more basic oxychloride. Next by means of an alkali (ammonia, *U. S. P.*, 1870) or alkaline carbonate (sodium carbonate, *Br. Ph.*), the oxychloride is converted into an antimonous oxide, and, to prevent the formation of the higher oxides, is dried at a low heat. The process should be conducted under a flue to carry off the deleterious gases.

Description and Tests.—"A heavy, grayish-white powder, without odor or taste, and permanent in the air. Almost insoluble in water, and insoluble in alcohol. Nitric acid fails to dissolve it, but it is readily soluble in hydrochloric acid without effervescence, and also in a warm solution of tartaric acid, or in a boiling solution of potassium bitartrate. When heated, the oxide turns yellow, becoming white again on cooling, and at a dull-red heat fuses to a yellowish liquid, which concretes, on cooling, to a crystalline mass of a pearly color. At a higher temperature, it sublimes, producing colorless and transparent, or white, shining, needle-shaped crystals"—(*U. S. P.*). The tetroxide, known also as *antimonous-antimonic oxide* (Sb_2O_4 or $\text{Sb}_2\text{O}_3 \cdot \text{Sb}_2\text{O}_5$), is formed when the antimonous oxide is slowly heated in the air.

"On dropping its solution in hydrochloric acid into water, a white precipitate is produced, which is at once changed to orange by hydrogen sulphide T.S. If 1 Gm. of the oxide be dissolved with the aid of 5 Gm. of tartaric acid in a little water, and the solution diluted with water to the measure of 100 Cc., portions of this solution should not be affected by test-solutions of silver nitrate (absence of chloride), barium chloride (sulphate), or potassium ferrocyanide (iron and other metals). If a solution of the oxide in hydrochloric acid be diluted with water, until it just begins to become permanently turbid, and then precipitated with hydrogen sulphide, this precipitate, when collected and thoroughly washed, should be completely soluble in ammonium sulphide T.S. (absence of copper and lead). If 1 Gm. of the oxide be dissolved in hydrochloric acid, and to this solution 1 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic) be added, together with a small piece of pure tin-foil, no turbidity or coloration should ensue within 1 hour (limit of arsenic)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This product is seldom used in medicine, and never by Eclectic practitioners. Owing to its comparative insolubility, it is less nauseating and less apt to provoke emesis than the other antimonials, which in the main it resembles in action. Dose: 2 to 4 grains. This article is generally employed in the preparation of the various medicinal salts of antimony. It has been occasionally used as a sedative, in doses of from 1 to 10 grains, though its action is uncertain, being sometimes inert, and again causing violent emesis.

ANTIMONII SULPHIDUM (*U. S. P.*)—ANTIMONY SULPHIDE.

FORMULA: Sb_2S_3 . MOLECULAR WEIGHT: 335.14.

"Native antimony sulphide, purified by fusion, and as free from arsenic as possible"—(*U. S. P.*).

SYNONYMS: *Antimony trisulphide, Antimonous sulphide, Black or Crude antimony,*

Antimonium crudum, Sulfuretum stibicum, Antimonii sulphuretum (U. S. P., 1870).
Antimonium nigrum (Br., 1867).

Source and History.—Under the name *stimmi*, the ancients employed this metallic compound as a cosmetic and topical remedy for skin diseases. It is found in Europe (chiefly in Germany and France), Nevada and Arkansas, New Brunswick and Borneo, as an ore denominated *stibnite*, and is usually associated with galena, quartz, heavy spar, calc spar, and iron pyrites. It is separated by melting it, after which, it is run into earthen receivers, cooled, and powdered. This is called *crude antimony*, which name should not be confused with that for metallic antimony. Crude antimony usually contains iron sulphide, and traces of the sulphides of lead, copper, and arsenic. Powdered coal, chalk, and marble, are frequently found as adulterants.

Description and Tests.—Before powdering and purifying, crude antimony usually has the shape of the conical vessels in which it has cooled. Outside it is blackish, but when broken, exhibits a crystalline, needle-like appearance, of a blue-gray or steel-like lustre. Its density ranges from 4.5 to 4.7. When drawn across a white object it leaves a black mark upon it. Officially it is described as in "steel-gray masses of a metallic lustre, and a striated, crystalline fracture, forming a black or grayish-black, lustreless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. At a temperature below a red heat, the sulphide fuses to a dark-brown liquid. If 1 Gm. of the powdered sulphide be digested and finally boiled with 10 Cc. of hydrochloric acid, it should dissolve without leaving more than 1 per cent of residue. This acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate which is soluble in a solution of tartaric acid. After the separation of the precipitate by filtration, the filtrate yields an orange-red precipitate with hydrogen sulphide T.S."—(U. S. P.). Antimony trisulphide occurs in amorphous form when precipitated from solutions (see *Antimonium Sulphuratum*).

It may be distinguished from coal dust by the failure of the latter to dissolve in hydrochloric acid, while marble or chalk effervesce when in contact with hydrochloric acid. An ounce bottle, dry and tared, will hold, when well shaken down, $2\frac{1}{4}$ ounces of antimony sulphide, and but $1\frac{1}{4}$ ounces of coal dust (*Proc. Am. Pharm. Assoc.*, 1885). By purification, the object of which is to deprive it as much as possible of admixed arsenous sulphide, crude (sulphide of) antimony yields the official

ANTIMONII SULPHIDUM PURIFICATUM (U. S. P.)—*Purified antimony sulphide, Purified antimony trisulphide.* $Sb_2S_3=335.14$.

Purification.—"Antimony sulphide, one hundred grammes (100 Gm.) [3 oz. av., 231 grs.]; ammonia water, fifty cubic centimeters (50 Cc.) [1 fl $\bar{3}$, 332 M.]; water, a sufficient quantity. Reduce the antimony sulphide to a very fine powder. Separate the coarser particles by elutriation, and, when the finely divided sulphide has been deposited, pour off the water, add the ammonia water, and macerate for 5 days in a well-closed vessel, agitating the mixture frequently. Then let the powder settle, pour off the ammonia water, and wash the residue by repeated affusion and decantation of water. Finally dry the product by the aid of a gentle heat"—(U. S. P.).

Description and Tests.—"A heavy, grayish-black, lustreless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. At a temperature below a red heat, it fuses to a dark-brown liquid. If 1 Gm. of the sulphide be digested, and finally boiled, with 10 Cc. of hydrochloric acid, it should dissolve without leaving more than 1 per cent of residue. This acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate, which is soluble in a solution of tartaric acid. After the separation of the precipitation by filtration, the filtrate yields an orange-red precipitate with hydrogen sulphide T.S. If 2 Gm. of the sulphide be mixed and cautiously ignited, in a porcelain crucible, with 8 Gm. of pure sodium nitrate, and, after cooling, the fused mass be boiled with 25 Cc. of water, there will remain a residue which should be white or nearly so, and not yellowish nor brownish

(absence of other metallic sulphides). On boiling the filtrate separated from the last-mentioned residue with a slight excess of nitric acid, until no more nitrous vapors are evolved, then dissolving in it 0.1 Gm. of silver nitrate, filtering again, if necessary, and cautiously pouring a few drops of ammonia water on top, not more than a white cloud, but no red or reddish precipitate should appear at the line of contact of the two liquids (absence of more than about 0.1 per cent of arsenic)"—(U. S. P.).

Action, Medical Uses, and Dosage.—Action, that of the antimony compounds in general. It was formerly combined with drastic purgatives. It is very seldom used in medicine at the present day. Dose: 5 to 15 grains.

Antimony and Its Compounds.—ANTIMONIUM, *Antimony, Stibium*. Symbol: Sb. Atomic Weight: 120. Many minerals contain antimony, but the chief and almost only source of the commercial product is the native trisulphide of antimony (Sb_2S_3)—the ore *stibnite*. Though known at a very early time, it was first separated by the monk Basilus Valentine. The bulk of antimony comes from France and Germany, though other places also furnish it. France furnishes the best product, which is in plano-convex circular cakes packed in casks. Spanish antimony is formed into pigs; the English into cones. Iron, lead, and arsenic are always present. To obtain the metal, stibnite is melted and the fused sulphide roasted in contact with the air to crude oxide of antimony. It is then intermixed with powdered charcoal previously saturated with solution of sodium carbonate, and roasted. Or, metallic iron and purified sulphide of antimony are fused together, iron sulphide and metallic antimony resulting. The product is then run into molds. Antimony is a crystalline mass of hard, brittle, silver-white metal, having a density of 6.7 or 6.8. It is unaffected by cold air, but when heated in the atmosphere, oxidizes, and heated in the presence of a current of hydrogen, volatilizes. It is not affected by cold, diluted sulphuric acid; hot sulphuric acid forms with it a sulphate; hot hydrochloric and cold nitrohydrochloric acids dissolve it. The elements of the sulphur and chlorine groups, and phosphorus and arsenic, combine with it directly. Some alloys are prepared with antimony. *e.g.*, type metal. The *antimony black* (not *black antimony*) employed to give a steel-like polish to casts and patterns, is a form of metallic antimony produced by precipitating the solution of the trichloride with zinc. Antimony forms three oxides, viz.: antimony trioxide (Sb_2O_3), antimony tetroxide (Sb_2O_4), and antimony pentoxide (Sb_2O_5), the last two of which are not employed in medicine. Antimony tetroxide is *antimonous oxide*, and forms with water, *antimonous acid*, the salts being known as *antimonites*; antimony tetroxide is also known as *antimonous-antimonic oxide* (Sb_2O_4 or Sb_2O_5); antimony pentoxide is *antimonic oxide*, producing with water, *antimonic acid*, a lemon-yellow powder, the salts of which are the *antimonates*. *Antimony ash* (*cinis antimonii*) is an impure tetroxide produced by gradually heating to redness the black sulphide in contact with the air; if this ash be fused with a little black antimony it forms *antimonial glass* (*vitrum antimonii*) a garnet-red, transparent mass. *Liver of antimony* (*hepar antimonii*) is formed when small amounts of potassium nitrate and black antimony (equal parts) are ignited and when the resulting potassium sulphate and sulphantimonate are removed from it by exhausting with water, *crocus of antimony* (a mixture of oxide and sulphide chiefly) remains. *Diaphoretic antimony* (*antimonium diaphoreticum*) is prepared like liver of antimony, excepting that twice the quantity of nitrate potassium is employed. It contains antimony oxide, sulphate, antimonate and nitrate and nitrite of potassium in variable amounts. Metallic antimony may be recognized by dissolving it in aqua regia and evaporating off the solvent. When the residue is dissolved in hydrochloric acid, precipitates are obtained with water (oxychloride, soluble in tartaric acid), with hydrogen sulphide gas (Sb_2S_3 , orange-red antimonic sulphide), or the liquid may be subjected to Marsh's test (see *Acidum Arsenosum*).

ANTIMONII IODIDUM (SbI_3).—*Antimony iodide, Teriodide of antimony*. A dark, orange-red powder, yielded upon pulverizing the foliated crystalline mass produced by gently heating together in a Florentine flask, 3 parts of iodine and 1 part of metallic antimony, and allowing the product to cool. Water decomposes it. Dose: $\frac{1}{4}$ to 1 grain in pill as an alterative.

ANTIMONII ARSENAS.—*Antimony arsenate*. A snowy-white, heavy powder, employed in certain portions of Europe (Russia) as an alterative in doses of $\frac{1}{16}$ grain 4 times a day. It is composed nearly half (44 per cent) of arsenic acid.

ANTIMONII TRICHLORIDUM ($SbCl_3$).—*Antimony trichloride, Antimony terchloride, Butter or oil of antimony, Muriate of antimony, Sesquichloride of antimony*. As formerly prepared by placing in a glass retort 3 parts of pure metallic antimony and 8 parts of mercuric chloride, and gradually heating, butter of antimony was produced, subliming and condensing in the neck of the retort as a white, thick, unctuous, semitransparent, inodorous substance, having a very caustic taste. Soubeiran prepared it by dissolving, with the aid of a gentle heat, 1 part of sulphide of antimony and 5 parts of hydrochloric acid, allowing the mixture to stand, and then decanting off the clear fluid, evaporating, and distilling almost to dryness. As obtained by these processes, butter of antimony is decomposed by water, and attracts moisture from the air and becomes yellow. It melts at $100^\circ C.$ ($212^\circ F.$) and volatilizes a little above this temperature, forming on cooling, tetrahedral prisms. The "butter of antimony" of the present day is a reddish solution produced by dissolving antimony trisulphide, 1 part, in hydrochloric acid, 4 parts, employing heat, filtering, and evaporating to 2 parts. Its color is due to iron and other metallic impurities, and the solution when distilled is a colorless solution of $SbCl_3$ (see *Liquor Antimonii Chloridi*—Br.).

ANTIMONIUM SULPHURATUM (U. S. P.)—SULPHURATED ANTIMONY.

"Chiefly antimony trisulphide ($\text{Sb}_2\text{S}_3=335.14$); with a very small amount of antimony trioxide"—(U. S. P.).

SYNONYMS: *Kermes mineral*, *Antimonii sulphuretum præcipitatum* (Dub.), *Antimonii ozysulphuretum* (Lond.), *Antimonii sulphuretum aureum*.

Source and History.—The monk, Basil Valentine, seems to have been the first to obtain what was subsequently known as *golden sulphur* (*sulphur auratum* of Quercetanus, 1603), and *antimonial kermes* (*kermes minerale* of Simon, 1719). Glauber had, however, already prepared the latter substance by making a hot solution of black antimony in potassa and cooling the product. Rose, in 1825, and Fuchs, in 1833, made clear the fact that *Kermes mineral* was nothing else than amorphous antimony sulphide (R. & S.). All the processes—and they were numerous—result in producing a mixture of one or the two sulphides of antimony and some oxide of antimony. That of the U. S. P. is an almost pure antimony trisulphide (Sb_2S_3). That of the *German Pharmacopœia* is pure antimony pentasulphide (Sb_2S_5).

This preparation, though official under the name *Kermes mineral*, is not the original mixture of that name (a description of which will be found below under *Related Compounds*). There are three preparations of sulphur and antimony: (1) an *amorphous precipitated antimony sulphide* (Sb_2S_3), orange-red in color; (2) a mixture containing some antimonious oxide known as *Kermes mineral* ($[\text{Sb}_2\text{S}_3 + \text{Sb}_2\text{O}_3]$, of a red-brown color; (3) and *antimonic sulphide* (antimony pentasulphide), (Sb_2S_5), known as *golden sulphur* or *golden sulphide of antimony*.

Preparation.—"Purified antimony sulphide, one hundred grammes (100 Gm.) [3 oz. av., 231 grains]; solution of soda, twelve hundred cubic centimeters (1200 Cc.) [40 fl. 3, 277 M]; distilled water, diluted sulphuric acid, each, a sufficient quantity. Mix the purified antimony sulphide with the solution of soda and three thousand cubic centimeters (3000 Cc.) [91 fl. 3, 203 M] of distilled water, and boil the mixture over a gentle fire for 2 hours, with frequent stirring, and occasionally adding distilled water so as to preserve the same volume. Strain the liquid immediately through a double muslin strainer, and drop into it while yet hot, diluted sulphuric acid, so long as it produces a precipitate. Wash the precipitate with hot distilled water until the washings are at most but very slightly clouded by barium chloride T.S.; then dry the precipitate at a temperature not exceeding 25°C . (77°F .), and rub it to a fine powder. Keep the product in well-stoppered bottles, protected from light"—(U. S. P.).

Crystallized antimony sulphide requires the aid of heat to dissolve it in alkaline fluids. The amorphous form dissolves in cold solutions. Such a solution (soda), as directed in the official process, contains sodium meta-antimonite (NaSbO_2) and sodium sulphantimonite (Na_2SbS_3), according to the following equation: $\text{Sb}_2\text{S}_3 + 4\text{NaOH} = \text{Sb}_2\text{S}_3\text{Na}_2 + \text{SbO}_2\text{Na}$. These bodies are decomposed upon the addition of the sulphuric acid, whereby antimonious sulphide precipitates, thus: $\text{Na}_2\text{SbS}_3 + \text{NaSbO}_2 + 2\text{H}_2\text{SO}_4 = 2\text{Na}_2\text{SO}_4 + \text{Sb}_2\text{S}_3 + 2\text{H}_2\text{O}$. The reaction does not take place quantitatively in this manner, as some hydrogen sulphide is liable to escape, resulting from the action of the acid upon the sulphantimonite. Consequently some undecomposed antimonite is precipitated with the sulphide. The official directions should be closely followed to insure, as nearly as possible, uniform results. Atmospheric exposure and state of concentration of the alkali solution, affect the composition of the product.

Description and Tests.—"An amorphous, reddish-brown powder, becoming lighter in color on exposure to light, and having neither odor nor taste. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. When heated in a dry test tube, it emits moisture and leaves a black residue. If 1 Gm. of sulphurated antimony be gently heated with 10 Cc. of hydrochloric acid, it should dissolve, with the exception of a slight residue, which, when washed and dried, should burn on the application of a flame, with the characteristic odor of sulphur, leaving not more than a scanty ash. The acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate, which, after being washed and dried, should

weigh not less than 85 per cent of the original weight of the sulphide. The liquid filtered from this precipitate yields an orange-red precipitate with hydrogen sulphide T.S. If 1 Gm. of sulphurated antimony be shaken with 20 Cc. of hot water, the filtrate should be neutral to test paper, should not be rendered more than slightly opalescent by barium chloride T.S. (limit of sulphate), or silver nitrate T.S. (limit of chloride), and should not be affected by ammonium oxalate T.S. (absence of calcium). When tested for arsenic, as described under purified antimony sulphide, it should afford no reaction beyond the limit prescribed for the latter"—(U. S. P.).

Action, Medical Uses, and Dosage.—This agent is not used in Eclectic medicine. It possesses the qualities of antimonials in general, and is administered in from 1 to 2 grain doses as an alterative, and in from 5 to 20 grains as an emetic.

Related Compounds.—**ANTIMONII OXYSULPHURETUM** (U. S. P., 1870). *Oxysulphuret of antimony, Kermes mineral.* This preparation was formerly official. It is prepared by the *dry process* by heating in a crucible 2 parts of antimony trisulphide and 1 part of potassium hydroxide; pulverize the mass thus obtained, and boil it with 10 or 12 parts of water; filter the liquor while boiling, and the kermes precipitates on cooling. In the *humid way* it is prepared by boiling for $\frac{1}{2}$ hour 1 part of finely powdered sulphide of antimony, 22.5 parts of crystallized carbonate of sodium, and 250 parts of water; kermes precipitates likewise on cooling. The last mode gives a finer article, preferred to that by the former process. It is a reddish-brown powder with a tinge of purple, of a velvety appearance, light, inodorous, of a slowly-developed, metallic taste, and insoluble in water or alcohol. Hot hydrochloric acid dissolves it, hydrogen sulphide being evolved. Exposed to air or light, it loses its red color and velvety aspect. It is completely soluble in ammonium sulphide. Heated to a red heat with charcoal, it is converted into metallic antimony. It is a mixture of Sb_2S_3 and Sb_2O_3 . Kermes mineral, in doses of from 6 to 10 grains, is an emetic, but its action is uncertain. In smaller doses, say from $\frac{1}{2}$ grain to 1 or 2 grains, in mucilage, it is a stimulant, expectorant, nauseant, and diaphoretic, and was formerly employed in the last stage of "*peripneumonia*" (pneumonia), in *chronic catarrhs, humid asthma, cutaneous diseases, gout, rheumatism*, etc.; it is seldom used in this country except among German practitioners. It should have no place in therapy.

ANTIMONII PENTASULPHIDUM (Sb_2S_5), *Antimony sulphide. Golden sulphur, Golden sulphuret of antimony. Sulphur stibiatum aurantiacum, Sulphur auratum antimonii.*—As originally prepared, by boiling antimony sulphide in caustic potash solution and adding sulphuric acid, a golden-red powder was obtained, containing Sb_2S_5 , with some Sb_2S_3 and Sb_2O_3 . The *German Pharmacopœia* directs a pure pentasulphide instead of this mixture. Boil a solution of crystallized sodium carbonate (70), in water (250); mix with a milk prepared from lime (26) and water (80). Add washed antimony sulphide (36) and sublimed sulphur (7); boil until no longer of a gray color, filter and crystallize. These crystals (24 parts) having the composition $Na_2SbS_5 \cdot 9H_2O$, and known as *Schlippe's salt*, are dissolved in water (700) and added to a solution of sulphuric acid (9) in water (200). The pure salt (Sb_2S_5) precipitates, and is washed and dried. A tasteless, odorless, orange-colored powder, which when sublimed evolves sulphur, leaving behind black antimonious sulphide. It wholly volatilizes at a red heat. It is not now employed medicinally. It was formerly used as an alterative in *chronic affections of the skin, rheumatism, secondary venereal diseases, and chronic hepatitis*; it is one of the constituents of Plummer's Alterative Pill. The dose is from 1 to 3 grains every 6 hours; when over 5 grains, the dose will be apt to occasion emesis.

ANTIPIRYNUM.—ANTIPIRYNE.

FORMULA: $C_6H_5N.CO.CH:CCH_2NCH_3 = (C_{11}H_{13}N_2O).$

MOLECULAR WEIGHT: 187.65.

SYNONYMS: *Analgesin, Antipyrin(e), Methosin(e), Methozine, Phenazone, Phenazon, Analgesine, Dimethyl-oxyquinizine, Phenylidimethylpyrazolon, Dehydrodimethylphenylpyrazine, Phenazonum* (Br.).

A compound derived from coal-tar or prepared synthetically. "A crystalline substance obtainable from phenylhydrazine"—(Br.).

Source and Preparation—Knorr first produced this compound in 1883. The original way of preparing it is as follows: Phenylhydrazine ($C_6H_5HN.NH_2$) is allowed to react, in the cold, upon aceto-acetic ether ($CH_3.CO.CH_2.COOC_2H_5$), whereby water is displaced and phenylhydrazine aceto-acetic ether is formed. This oily product heated to $100^\circ C.$ ($212^\circ F.$) evolves alcohol, leaving behind phenylmethylpyrazolon, formerly called *methyloxychinizin* ($C_{10}H_{11}N_2O$). This body is then changed into phenylidimethyl-pyrazolon iodide by heating it with methyl iodide in contact with methylic alcohol. It is then treated with sulphurous acid solution until decolorized, the alcohol separated by distillation, the residue treated

with concentrated soda solution, and the heavy, oily base, after solidification, recrystallized from ether or toluene. By a patented process of 1890, antipyrine is made by the action of phenylhydrazine upon a compound ether; *e. g.*, ethyl-ether of beta-bromo, or chlorobutyric acid. It was demonstrated by Lederer, in 1891, that this process does not yield antipyrine, but an isomer. Antipyrine has also been prepared (1892) from the interaction of phenylhydrazine and crotonic acid (Knorr and Duden). Various processes of similar principle have been patented subsequently to obtain pyrazolon derivatives; *e. g.*, by the interaction of beta-chlor-lactic acid and phenylhydrazine (Pfleger and Krauth, 1893).

Description.—Antipyrine usually occurs as crystalline laminæ, or when crystallized from water as prismatic crystals. As found in trade it forms a white, reddish-white, or whitish powder, having a taste mildly bitter, and scarcely any odor. It dissolves very readily in water, alcohol, chloroform, and benzene, less soluble in ether (about 1 in 50), and scarcely at all in benzin and carbon disulphide. It fuses at 113° C. (235.4° F.). It completely volatilizes by heat, but not without decomposition. Its solution in water is neutral to litmus, and should not respond to hydrogen sulphide, but precipitates with most alkaloid-test reagents, corrosive sublimate, basic acetate of lead, and Fehling's Test Solution, which latter is reduced by it. A characteristic reaction for antipyrine consists in the formation of green crystals of nitroso-antipyrine, when antipyrine, together with one-third its weight of sodium nitrite, is dissolved in about 8 times its weight of water, and a few drops of diluted acetic acid are added, and allowed to stand for 1 hour. The same reaction takes place with sweet spirit of nitre containing free acid (Flückiger and Nagelvoort). In dilute solution (about 1 in 20,000) merely a green coloration is formed, which deepens with the quantity of antipyrine employed. M. T. Schaak (1894) has proposed a method of determining antipyrine quantitatively by means of this reaction. A concentrated solution of antipyrine turns deep red by the addition of an acid-free solution of ferric chloride. The color disappears or turns light yellow with sulphuric acid. Antipyrine gradually decolorizes wine. By the direct contact of acids, salts are formed, showing this body to be a pronounced base. When first obtained it was erroneously supposed to be a derivative of quinoline. It is incompatible with solutions of amyl nitrite, hydrocyanic acid, spirit of nitrous ether (sweet spirit of nitre), chloral hydrate, salicylate and bicarbonate of sodium, carbolic acid, tannic acid, etc. It may be combined with aromatic syrups for administration.

Action and Toxicology.—Antipyrine is an extremely uncertain agent in its effects. Even small doses have occasioned alarming symptoms, a peculiarity being a characteristic livid hue of the countenance, which is attended with symptoms of collapse. As small a quantity as 3½ grains has produced death, while on the other hand a woman survived 1 ounce at one dose, and another consumed 1½ ounces in five days, the former with no other damage than a half-day's unconsciousness, and the latter swollen extremities and cyanosis. The usual symptoms from physiological doses are a languid and uneasy feeling, rise of temperature, peculiar cyanotic countenance, dyspnoea, hysterical phenomena, and often a rubeoloid eruption lasting about five days, followed by slight desquamation. The eruption sometimes assumes an erythematous character, or severe urticaria, or dermatitis, with œdema, or watery blebs and bloody blisters may follow its use. Even in doses regarded medicinal, it has occasioned coldness, copious sweating, irregular heart action, vomiting, and other symptoms of depression, bordering on collapse. Occasional symptoms are stomatitis, laryngeal complications, amaurosis, tinnitus, violent cough, coryza, burning in the mouth and fauces, metallic taste, gastro-enteritis, and mental dullness. More rarely general neuralgic pains, vomiting, diarrhoea, dysuria, convulsions, paralysis, and sopor are its effects. A toxic dose presents vertigo and tremors, distressing head-symptoms, increased pulsation, profuse sweating, reduction of temperature, oppressed respiration, exaggerated reflexes, somnolence, coma, profound insensibility, ster-tor, pupillary dilatation, convulsions, and death.

The reduction of temperature, which is marked in febrile states, has been shown to be independent of the profuse sweating produced. The reduction occurs whether sweating be present, or when it is prevented by such agents as atropine. The action of antipyrine, in toxic doses, upon the brain, is first to stimulate and

then to depress; the spinal nerves are paralyzed, and the respiratory centers first stimulated and finally depressed and paralyzed. Blood-pressure is increased by large doses and depressed by lethal doses. Doses short of toxic have, as a rule, but little physiological effect upon the respiratory organs. The urinary secretion is markedly diminished by antipyrine, though this is the channel by which it is principally eliminated, the drug appearing in the urine within 30 minutes after being administered. It has been detected in human milk, and may therefore affect nursing infants. The teeth are said to be colored by this agent. Symptoms of collapse from antipyrine should be met by alcoholic stimulants and by the subcutaneous use of atropine sulphate.

Medical Uses and Dosage.—Antipyrine has been used as an analgesic, nerve sedative, antispasmodic, antipyretic, local anæsthetic, topical hemostatic, antigalactagogue, and to restrain secretions from the kidneys and bowels. Its chief value is in its power to control pain and spasm. It markedly reduces temperature in *febrile states*, but the preponderance of fast-accumulating evidence, even in the old school where it has been so largely and so fatally used, shows it to be wholly undesirable as an antipyretic. While its power to reduce temperature is undisputed, it is well known that it does not, in the least, shorten the course of any of the febrile disorders, and is open to the serious objection of favoring depression and collapse, and tends to increase the difficulty upon which many fevers depend in causing the retention in the system of morbid products, whose elimination is prevented by its restraining power over renal activity. There are a few febrile complaints in which it does apparent good. These are *surgical fever* after operations and *puerperal septicæmia*, with intensely high temperature. Here it should be employed to reduce the temperature somewhat, but it must not be carried too far. In the high temperature of respiratory lesions it is said to be of some value, as in *pneumonia* and *pleurisy*. It has no action upon the diseased structure, except to relieve pain and lower temperature. Undoubtedly, the majority of cases of "heart failure," which have been reported in the past few years, are due more to the indiscriminate use of this and other coal-tar derivatives than to any other agency. Antipyrine has been used to control the febrile phenomena of *phthisis*, but the unpleasant and debilitating sweating produced more than overbalances the good it may do. *Thermic fever* (congestive form) from *sun-stroke* and not that from heat exhaustion, is said to be benefited by it. *Diarrhœa*, *diabetes mellitis* and *insipidus*, and other excessive secretions, except of the skin, have been restrained by its use. *Epilepsy*, purely functional, *tetanus*, *asthma*, and other *spasmodic disorders*, have been treated by it with both success and failure. *Chorea* and *whooping-cough*, however, seem to be more amenable to it, and it is accredited with shortening the duration of the latter disease.

In painful and spasmodic disorders it will find its best field of action. Its use in *migraine* and other forms of *headache*, especially of neuralgic character, is well known. However, much danger attends its constant employment, as prolonged prostration and debility have followed such use. Webster believes it to be cumulative (*Dynam. Ther.*, 115). It is used largely to control pain in *sciatica*, *tetanus*, *dysmenorrhœa*, *gravel*, *locomotor ataxia*, *neuritis*, *rheumatism* (muscular and articular), *arthritis* (rheumatic), *gout*, *angina pectoris*, *renal* and *hepatic colic*, *syphilis*, *neuralgia of zona*, *after-pains*, and to allay *itching* and *burning pain of cutaneous disorders*. *Palpebral neuralgia*, *sclero-choroiditis*, *episcleritis*, *iritis*, *keratitis*, *irido-choroiditis*, *detached retina*, *pain after cataract operations*, *toxic amblyopia*, and *floating bodies* in the vitreous humor are among the eye affections in which it has been used, though it is not looked upon with special favor by our ophthalmologists. Locally it has been employed as an antiseptic dressing to *ulcers* to relieve pain, and as a local hemostatic.

The large doses formerly recommended—75 to 90 grains, and subsequently 15 to 50 grains—are seldom now given. The doses should not, at any time, exceed 20 grains, and 5 grains is about the best dose for average purposes. For young children give 1 grain every hour until 3 doses have been taken. It may be administered in mint water, aromatic syrup, or coffee. Subcutaneously, 5 grains is the safest maximum dose. It has also been given by enema and suppository.

Specific Indications and Uses.—Pain and spasm; high temperature in surgical and puerperal fevers; migraine.

Antipyrine Derivatives.—**IODOPYRINE.** *Iodopyrin, Iodantipyrin.* This salt is prepared by mixing with an alcoholic solution of antipyrine a hot alcoholic solution of iodine, the iodine and antipyrine being present in such a proportion as to form a mono-iodide. When left standing a few days, iodopyrine crystallizes. If the proportion of iodine be twice the former, a diiodide of antipyrine is produced. Iodopyrine forms colorless, silky, acicular crystals, almost without taste or odor. It is practically insoluble in cold water, but dissolves freely in hot water. It fuses at 180° C. (320° F.). This agent sometimes occasions copious diaphoresis, and is antipyretic, though it does not shorten the period of febrile diseases. Dose, 1 to 4 grains.

BROMOPYRINE.—*Monobromantipyrin* ($C_{11}H_{11}BrN_2O$). White acicular crystals, which melt at 114° C. (237.2° F.). Scarcely soluble in water, hot or cold, but dissolves easily in chloroform and alcohol. Its action has not yet been determined.

BENZOPYRINE.—*Benzoate of antipyrine.* Add antipyrine to a solution of benzoic acid at 100° C. (212° F.), below which point the resulting salt forms with the production of a yellow fluid, which congeals as a mass of opaque crystals. It is practically insoluble in water, while both ether and alcohol dissolve it.

SALIPYRINE.—*Salipyrasolon, Salasolon, Salicylate of antipyrine, Antipyrine salicylate.* A definite salt formed by the interaction of salicylic acid and antipyrine. It is prepared by heating together molecular quantities of the two named bodies. An oily fluid results, which solidifies when cool, and is then crystallized from alcoholic solution as a white salt, with a somewhat pleasant taste, but no odor. It is practically insoluble in water, is partially soluble in ether, and freely so in alcohol or benzene. It fuses at 91.5° C. (196.7° F.). Its solution is faintly acid, and the taste at first sweet, then bitterish. If prepared from solutions of salicylic acid in water and of antipyrine in ether it slowly deposits beautiful crystals, which dissolve in ether with difficulty. This agent is antipyretic, antirheumatic, and antineuralgic. Like antipyrine it may occasion an eruption, and sometimes acts as an emetic. It is eliminated by the kidneys. Dose, 5 to 15 grains, and not more than 40 grains should be administered in 24 hours.

ANTIPYRINUM AMYGDALICUM.—*Tusol.* This substance was introduced in 1894 as a remedy for *whooping-cough*, and is obtained by fusing together 188 parts of antipyrine with 152 parts of mandelic acid, which proportion represents equimolecular quantities. The product forms bitter crystals, easily soluble in water. Alkaline liquids and milk decompose it. The doses vary from $\frac{1}{2}$ to 1½ grains for children less than 1 year, to be given 2 to 3 times a day; for children of 1 to 2 years of age, the dose is 1½ grains, to be given 3 times a day. The dose may be increased to 3½ grains, or even 6 grains, 3 to 4 times a day for older children.

PHENOPYRINE. Equal amounts of antipyrine and pure carbolic acid (phenol), well dried, triturated together form phenopyrine. It is a colorless and inodorous, oily liquid, which crystallizes upon standing. Does not dissolve in cold water.

PICROPYRINE. Prepared by adding, drop by drop, a strong solution of antipyrine to a concentrated solution of picric acid in water. The resulting precipitate is then recrystallized from hot water. It forms fine acicular crystals of the characteristic yellow color of the picrates.

NAPHTHOPYRINE. *Beta-naphthol-antipyrine.* This product is the result of triturating antipyrine 1 part (by weight), with 2 parts of beta-naphthol. Is somewhat soluble in boiling water, soluble in ether and alcohol, but does not dissolve in cold water.

PYROGALLOPYRINE. Triturate together 1 part (by weight) of antipyrine, and 2 parts of pyrogallol. If the solutions of the two be mixed and allowed to stand a few hours pyrogallopyrine crystallizes in handsome prisms. Its solubility is like that of *naphthopyrine* (which see).

RESORCYLAIGIN is a new antiseptic prepared in 1893 by the action of resorcyate of potassium upon antipyrine. It is little soluble in water, easily soluble in alcohol, has an acid reaction, and forms salts with alkalis. The ammonium salt is easily soluble.

TOLYPYRIN is a copyrighted name given to a homologue of antipyrine elaborated by H. Thoms in 1892. It is prepared by the action of paratolyl-hydrazine upon aceto-acetic ether. Its taste is bitter; it has a fusing point of 136° to 137° C. (276.8° to 278.6° F.), is soluble in 10 parts of water, in alcohol, almost insoluble in ether; with ferric chloride, or with nitrous acid it behaves like antipyrine. A specific reaction for tolypyrin is said to be as follows: If to a quantity of tolypyrin, about $\frac{1}{2}$ to 1 gramme, be added, 2 Cc. of a 25 per cent solution of nitric acid, the liquid turns wine-red, and becomes light-yellow when ammonia is added.

TOLYSAL.—*Tolpyrinum salicylicum* (1893), is said to be valuable as an antirheumatic, antineuralgic, and antipyretic agent.

Related Compounds.—**ANTITHERMIN.** *Phenyl-hydrazin-lævulinic acid* ($CH_3.C[N_2HC_6H_5].CH_2.CH_2.COOH$). This compound precipitates when phenylhydrazine (108 parts) dissolved in acetic acid is mixed with a solution of lævulinic acid ($CH_3.COCH_2.CH_2.COOH$) (116 parts), in water. By dissolving the resulting product in boiling water, and decolorizing with animal charcoal, it crystallizes as a colorless, lustrous salt, having scarcely any taste, and is very slightly soluble in alcohol and water. When heated to 170° C. (338° F.), it becomes phenylhydrazine lævulinic anhydride ($C_{11}H_{13}N_2O$). In 3 grain doses it is used in the febrile states of *pulmonary consumption* and *Bright's disease*.

AGATHIN.—*Salicylaldehyde alpha-methylphenylhydrazone* ($C_6H_4[OH].CH=N.N[CH_3].C_6H_5$). This salt results from the direct interaction of alpha-methylphenylhydrazine and salicylaldehyde. It forms greenish-white, crystalline plates which dissolve in ether and alcohol, but not in water. They are tasteless and odorless. It fuses at 74° C. (165.2° F.). Antirheumatic and antineuralgic in 5 to 8 grain doses 3 times a day. No untoward results have been observed from its use.

PYRAZOLE ($C_2H_4N_2$, or $\left\{ \begin{smallmatrix} CH=N \\ CH=CH \end{smallmatrix} \right\} : NH$). Formed by acting upon hydrazine with epi-

chlorhydrin in the presence of chloride of zinc. It forms in needles soluble in water, ether and alcohol. Of its derivatives, all of which paralyze the central nervous system (Tappeiner, 1891), *phenylmethylpyrazol carboxylic acid*, in daily doses of from 15 to 30 grains, is said to be an exceedingly active and harmless diuretic.

MIGRANIN. Said to be a mixture of antipyrine (about 9 parts), caffeine (about 1 part), and a small portion of citric acid. Given in 15 grain doses for the relief of *migraine* and the *headache of la grippe*.

ACETO-ORTHO-TOLUID ($C_6H_4NH_2C_2H_3O$). Needles, colorless, soluble readily in alcohol, ether, and hot water. Slightly tonic. Powerfully depresses temperature.

ANTIPYRINE-SALOL. Equal parts of salol and antipyrine fused together until of a brown color, remaining fluid when cool. Antiseptic, and applied by cotton tampons as a hemostatic in *hemorrhage* from the uterus (Coblentz).

APIS.—APIS.

The alcoholic tincture and the virus of *Apis mellifica*, Linné, the common honey-bee.

Class, Insecta; *Order*, Hymenoptera; *Family*, Apidæ.

COMMON NAMES: *Honey-bee*, *Hive-bee*.

History.—This well known bee inhabits the wilds in swarms, and is also kept in proper establishments for the purpose of obtaining its honey and wax. The insect is too well known to need a description here.

Preparation.—I. **TINCTURA APIS MELLIFICÆ**, *Tincture of apis*. The preparation of apis generally employed is the alcoholic tincture, which, for general purposes, may be prepared as follows: Place a swarm of live bees in a large jar and then by shaking them excite their anger. When this is accomplished, cover them with deodorized alcohol and allow them to macerate a month; then decant and filter the liquid. The homœopathic tincture is prepared in the same manner by using 1 part of live bees to 5 parts of diluted alcohol, macerating 8 days, decanting, straining, and filtering. Diluted alcohol is also preferred for their dilutions of this preparation.

II. **APIUM VIRUS.**—This form is used but little by Eclectics, but largely in homœopathy. It is obtained either by drawing the sting and poison-bag from a freshly killed bee, inserting the sting into a small glass tube, and by compressing the bag, squeezing the poison into it. Or, with a pair of forceps seize a live bee and allow it to grasp a small piece of sugar. It will at once sting into the lump which will absorb the virus. This is to be repeated until a sufficient amount is secured to start a trituration, which is prepared like other homœopathic triturations as stated under *Triturations*.

Action, Medical Uses, and Dosage.—This remedy had its origin as a medicine in the homœopathic school, but is now a general favorite among Eclectics for certain diseased conditions. Apis is diuretic, alterative, and diaphoretic. It specifically influences the urinary tract, small doses somewhat resembling cantharis in action, in removing irritation, and in larger doses, stimulating the renal organs and other portions of the urinary passages. The small dose may be employed if there be irritation, even though inflammation exists. Aconite, veratrum, and like agents, promote the action of apis, while ammonia and alcoholic liquors are antagonistic to it. It is specifically indicated where we have hot, burning, dry, itching surfaces; and where there is constant desire, but inability to urinate, the urine being dark-red in color. Apis is one of the most certain diuretics in the *materia medica*, and is of very great value in *suppression* and *retention of urine*, from atony. It may be used even when there is active inflammation: R Specific apis, gtt. v; aqua, flʒiv. Mix. Teaspoonful every hour; or use an infusion of from 15 to 20 bees in water, 1 pint, for the usual urinary difficulties indicated above. It is a very useful remedy for *urethral* and *cystic irritation*, with burning, stinging pain, and constant and annoying *tenesmus*. *Chronic nephritis* and *cystitis* are sometimes cured by it. It serves a good purpose in diseases of women characterized by heat and a sensation of burning, with pain in the bladder and urethra, and constant desire to pass water. These conditions are relieved by it quicker than by any other agent. In *menorrhagia*, *amenorrhœa*, and *leucorrhœa*, with acute congestion of the ovaries, or in simple *ovarian congestion*, the parts being tender and painful, apis often gives prompt relief. *Genital puffiness* with irritation, and *labial inflammation* of the same character, are

cured by it. **R** Specific apis, gtt. x; aqua, fl̄iv. Mix. Teaspoonful every 4 hours. Owing to its power of relieving renal irritation and engorgement, thereby increasing function, apis is an exceedingly useful agent in *anasarca*, *ascites*, and *hydrothorax*, provided the kidneys are in an active condition. For these troubles: **R** Specific apis, gtt. v; aqua, fl̄iv. Mix. Teaspoonful every hour. It is particularly useful in *post-scarlatinal dropsy*. *Inflammatory sore mouth* is benefited and often cured by apis. *Sore throats*, of an oedematous character, having a uniformly spread puffiness, as if the submucous tissues were involved—the parts appearing as if stung by a bee—are relieved by apis. These conditions are frequently met with as a complication of *erysipelas* and in the *angina of scarlatina*. It is often a prompt remedy for *vesicular erysipelas*, and for all *subcutaneous inflammations*, with burning, stinging, tense, and lancinating pains, and dermal irritation. We have no better agent for the treatment of *urticaria*, or “*hives*,” with soreness and intense itching, than apis. Puffiness is a strong indication in cutaneous diseases, and in *traumatic injuries* of the subcutaneous areolar tissues, it is often indicated by this symptom. It is a good remedy in *rubeola* and *scarlatina*, the usual indications being present. That form of *rheumatism* having the peculiar symptoms otherwise indicating apis, will be found to respond oftentimes to this remedy. We have known of well authenticated cases, where individuals suffering from rheumatism have been cured of that complaint after having been severely stung by the hive-bee. We do not recommend this form of hypodermatic injection, but prescribe for rheumatic conditions with blanched puffiness, and the peculiar stinging pain, as follows: **R** Specific apis, gtt. v; aqua, fl̄iv. Mix. Teaspoonful every 2 or 3 hours. Dose: Tincture of apis, $\frac{1}{2}$ to 5 drops; specific apis, $\frac{1}{4}$ to 2 drops. The larger doses in dropsies; the smaller, in cutaneous disorders, and in vesical irritation; infusion (12 to 20 bees, aqua, Oj), table-spoonful doses frequently.

Specific Indications and Uses.—Itching, with burning of the surface, especially of the genitalia or urinary passages (Scudder); hot, dry, burning, itching or stinging surface; puffiness of mucous tissues, with burning, stinging, or irritation, the parts appearing as if stung; hives; vesical and urethral irritation, with constant desire, but inability, to urinate, the urine being deep-red; puffiness of parts with tendency to oedema.

APOCYNUM (U. S. P.)—APOCYNUM.

The root of *Apocynum cannabinum*, Linné, (*Apocynum hypericifolium*, Aiton), gathered in autumn after the leaves and fruit have matured.

Nat. Ord.—Apocynaceæ.

COMMON NAMES: *Canadian hemp*, *Bitter root*, *Indian hemp*.

ILLUSTRATION: (See King's *American Dispensatory*, 8th ed., p. 114).

Botanical Source and History.—This is an erect, branching plant, from 2 to 4 feet high, which is found growing throughout the United States, on the borders of fields and in similar localities. The stem is covered with a strong fibrous bark, which is green when the plant grows in the shade, and of a reddish-brown color when in sunny localities, in which situations the plant is usually found. The fibrous bark was used by the Indians, and on this account, the name *Indian hemp* has been applied to this plant; but it is a bad term, as it has led to much confusion, from the fact that this is the common name for several other plants. The plant should *never* be designated by this name. The entire plant exudes a milky juice when wounded. The leaves are opposite, and attached to the stem at an acute angle. They exhibit considerable diversity of shape in plants that grow in different localities, and form several well-marked varieties; presenting, in the different varieties, modifications in outline from oblong to oval, with the bases of the leaves acute or subcordate. The most common form has oblong-lanceolate, veiny, entire leaves, on leaf-stalks, about $\frac{1}{2}$ of an inch long, and end in a short, mucronate point. The flowers are small, numerous, and in close, peduncled, flat cymes, which are shorter than the lateral branches. The calyx is small, with 5 narrow, sharp lobes; the corolla is 5-parted, with erect lobes, white or pale-red color, and but a little longer than the calyx. The stamens are 5,

small, distinct, and included. The pistil has 2 ovaries covered by 2 united, sessile, fleshy stigmas. The fruit, which is produced by only a few of the flowers, consists of a pair of slender, diverging pods, containing numerous small seed, which are furnished with a bunch of silky, white hair at the apex (see Fig. 27). This plant, also erroneously called *Bowman's root* in Kentucky and some other sections of country, is indigenous, inhabiting the same locations and blossoming in the same months as the *A. androsaemifolium*. It is replete with a lactescent juice, which becomes hard, like opium, under exposure to the air. The bark of the stem, when dry, from its fibrous, cohesive nature, is a superior article in the manufacture of rope, giving a white, strong, and durable production. A permanent brown or black dye, according to the mordant used, is obtained from a decoction of the plant.

Apocynum cannabinum.

from the *Apocynum cannabinum*. There is, however, a marked difference both in the external appearance and the internal constitution of these two roots, and those who have compared authentic specimens can distinguish the two at a glance.

Description.—The root of *A. cannabinum*, gathered in the autumn and dried, is about $\frac{1}{2}$ of an inch in diameter, wrinkled longitudinally, and marked by occasional transverse fractures through the bark, which show the white central portion. It consists of a bark, externally ash-gray in color, beneath which is a thin, brown, corky layer, and within this, the inner bark, which is of a pale-pink color. The remainder of the root is composed of white medullary matter, perforated by numerous longitudinal tubes, disposed more thickly in concentric circles about the fortieth of an inch apart, or forming a single circle. Radiating from the center are delicate medullary rays. When gathered in the spring, or in early summer, the center is pierced by a light pith, or a small cavity. The root, when dry, is brittle, and snaps readily, giving a clear, smooth fracture. As found in market, there are few, if any, fibers attached although, when fresh, the root is plentifully supplied with secondary roots; but as they are very brittle when dry, they do not long remain attached. We call attention to the exact engraving presented of the dry root, and also to a section of the root magnified (Fig. 27), and suggest that a comparison be made between these and those of *A. androsaemifolium* (Fig. 28). The woody portion of the root is slightly bitter; the bark is extremely bitter and disagreeable. It is described in the Pharmacopœia as follows: "Long, cylindrical, somewhat branched, 5 to 10 Mm. ($\frac{1}{4}$ to $\frac{3}{8}$ inch) thick, gray or brownish-gray, longitudinally wrinkled and transversely fissured; brittle; fracture short, white; the bark rather thick; the wood porous, spongy, with delicate medullary rays; inodorous; taste bitter, disagreeable"—(*U. S. P.*). Water readily takes up the active properties of the root, which are also partially soluble in alcohol; its virtues are impaired by age.

Chemical Composition.—Dr. Griscom, who analyzed the root in 1832, found it to contain tannic and gallic acids, gum, resin, wax, secula, *apocynin*, coloring matter, woody fiber, and, probably, caoutchouc. From the precipitate of the fluid extract, a white, waxy body without taste, and cane-sugar crystals were obtained by Prof. J. U. Lloyd in 1879. Two bodies having properties resembling

those of digitalin were obtained, in 1883, by Schmiedeberg; one, *apocynin*, an amorphous principle, resinous, nearly insoluble in water, but readily dissolved by ether and alcohol; the other, *apocynin*, a glucoside of a yellow color, dissolving freely in alcohol, but insoluble in ether, chloroform, and benzin. Boiling the former with chlorhydric acid renders it inert. Bromine and sulphuric acid give no test reaction with either of these bodies.

Action, Medical Uses, and Dosage.—Dr. Griscom states that this agent has four different and distinct operations upon the system, which it almost invariably produces, viz.: (1st) nausea or vomiting; (2d) this is followed by increased alvine discharges, which are succeeded (3d) by copious perspiration, and in many instances (4th) by diuresis. In full doses it occasions considerable sickness at the stomach, lessens the pulse, and produces an inclination to sleep, probably from some somniferous principle in it—copious vomiting soon ensues, and the other effects as above stated. Snuffed into the nostrils, the powder will excite sneezing. In diaphoretic doses it has proved beneficial in *intermittent* and *remittent fevers*, and *pneumonic affections*. A strong decoction in doses of a teaspoonful every 1, 2, or 4 hours, is exceedingly valuable in *irritable and congested uterus*, accompanied with nausea, vomiting, tympanitic abdomen, headache, and powerful pulsations of the abdominal aorta. In some cases it may be advantageously combined with *asclepias*. As a hydragogue cathartic, and also as a diuretic in those instances where this effect is displayed, it has been found most useful in *dropsy*. Indeed it has proved very efficient in dropsy and its accompanying symptoms, when associated with general debility or a strong tendency to struma, albuminuria being absent, removing the effusion without necessarily inducing watery stools. It is, however, seldom employed in dropsical complaints for its purgative action, but rather in the small dose for its action in removing cedematous infiltration, probably acting upon the heart by strengthening that organ, and thereby affecting the kidneys, secondarily inducing diuresis. Used for this purpose, it is the most certain diuretic in the *materia medica*. Certain conditions, however, govern its use. If dropsy be dependent upon structural lesions, as organic disease of the heart, liver, or kidneys, apocynum will not relieve the trouble, though it becomes a useful addition to digitalis, *strophanthus*, cactus, and other remedies used to mitigate the urgent symptoms. Neither would it act well where the pulse is quick and hard, evidencing circulatory obstruction, and in febrile disorders. The cases calling for apocynum are those of debility or weakness, that atonic state which readily permits exudation from the blood-vessels. Under such circumstances it is positive whether it be simple *cedema* or *anasarca*, *ascites*, or dropsy of any of the serous cavities. The indication is *watery fullness of tissues*, as if infiltrated. It may be puffiness of the eyelids, feet, or other parts; the parts pit upon pressure; and there may be a blanched, glistening appearance of the skin. Chronic cases, as a rule, are those in which it acts best, though it is of great value in *acute hydrocephalus*, as well as the chronic form, the fontanelles protruding, the sutures spreading, the eyes prominent, and the lids puffy. The dropsies following *ague* and *scarlatina* are particularly cases for its employment. In gynecological practice it is of value in *amenorrhœa*, *passive menorrhagia* and *leucorrhœa* with watery discharges, the uterus being in all these disorders full and relaxed. Usually there is cedema of some other part. In menorrhagia the profuse flow lasts too long and too frequently recurs. It is a good remedy for the depression attending old cases of *scrofula* and *syphilis*, and in *atonic dyspepsia* fulfils an important use in removing constipation and fluid accumulations when present. *Rheumatism* yields to it when cedema of a part of or whole of the body is present, or even where there is slight puffiness or glistening of the parts. Frequently it must be given with other antirheumatics.

Apocynum is a decided heart tonic. The conditions above-named, and a dilated condition of the cardiac ventricles, point to its use. It is not the remedy where the circulation is excited, with hard, quick pulse. Dr. E. R. Freeman reports an inveterate case of *angina pectoris* benefited by it. Cedema was a feature of the case. Dr. Waterhouse (*Ec. Med. Gleaner*, 1891) relieved the *præcordial oppression* of a smoker with it. Dr. J. C. Kilgour (*Ec. Med. Jour.*, 1886) declares it a decided antineuralgic, relieving *sciatic*, *crural*, and *lumbar neuralgias*. Prof. G. C. Gere (*Cal. Med. Jour.*) asserts that it is the most valuable of

deobstruents to relieve *renal congestion* in the second stage of *tubular nephritis* (*Dynam. Therap.*). Too much, however, must not be expected of it where there are structural changes of the vital organs. *Acute inflammation of the upper laryngeal and post-nasal region* is specifically met by this drug, according to Prof. Webster being nearly as positive as *phytolacca*, and preferable when the irritation does not extend beyond those parts, and is readily brought on by slight exposure (*Dynam. Therap.*). Goss found it to remove *ascarides* from the rectum when given in cathartic doses. As an emetic, from 12 to 30 grains of the powdered root-bark may be given; as a hydragogue or diuretic, the decoction is the best form in which to employ it—1 ounce of the root may be boiled in a pint of water, of which half a wineglassful, or even less, may be given 3 or 4 times a day. Smaller quantities of the decoction, given warm, will cause diaphoresis; as a purgative, the aqueous extract may be given in doses of from 3 to 6 grains. For its specific uses the decoction in small doses (a teaspoonful every 1 or 2 hours) or the specific medicine is preferred. R Specific apocynum, grt. x to 3j; aqua, fl̄iv. Mix. Sig. A teaspoonful every 1 to 3 hours. The decoction is most effectual.

APOCYNIN is reputed a powerful heart tonic, similar in action to *strophanthus* and *digitalis*.

Specific Indications and Uses.—*Watery fullness* of cellular tissues—*œdema*; puffiness of eyelids, and wrinkled lids as if the parts had recently been swollen; feet full and *œdematous*, pitting upon pressure; constipation, with *œdema*; scanty urine; skin glistening; circulation sluggish; passive hemorrhages, small in amount, with great depression, and *œdema* of the feet; *hemoptysis*; *menorrhagia*, profuse, too often and too long continued; full, relaxed uterus, with watery discharges.

APOCYNUM ANDROSÆMIFOLIUM.—DOG'S BANE.

The root of *Apocynum androsæmifolium*, Linné, gathered in autumn after the leaves and fruit have matured.

Nat. Ord.—Apocynaceæ.

COMMON NAMES: *Dog's bane*, *Indian hemp*, *Bitter root*.

ILLUSTRATIONS.—*Bot. Mag.*, 280; *Rigel's Med.*, 36; *Amer. Disp.*, 8th ed., Pl. 3.

Botanical Source, History, and Description.—*Apocynum androsæmifolium* has a close resemblance to *A. cannabinum*, but is found in more northern latitudes,

Apocynum androsæmifolium.

being the more common species in Canada and in the Northeastern States. The leaves are oval, roundish, about three-fourths as wide as they are long, and end in short, mucronate points. They are smooth, of lighter color on the under surface, and are attached to the stem at nearly a right angle, on leaf-stalks about $\frac{1}{4}$ of an inch in length. The flowers are larger than in *Apocynum cannabinum*, and are disposed in loose, terminal paniced cymes, extending beyond the leaves. The corolla is flesh-colored, with spreading lobes, and more than twice the length of the calyx. Our illustration was drawn from a plant furnished by Mr. F. H. Hosford. The root of this plant is rarely found in market. It bears a general resemblance to that of *Apocynum cannabinum*, although its distinguishing characteristics are well marked, and sufficiently distinct to forbid confusion, and to prevent substitutions from being practiced upon those who have compared the two roots. *Apocynum androsæmifolium* has a long running root. When dry, it is contorted, frequently having the woody remains of its stalks attached. It is shriveled longitudinally, and often marked by transverse fractures, that extend through the bark and

show the white woody center. Occasionally the bark scales off. The root breaks with difficulty, its central part being woody. Externally, the bark is dark-brown, white upon its inner surface, and readily separates from the central or ligneous part of the root; it is very bitter. The central part of the root is smooth and firm, bends before breaking, and usually requires considerable twisting before the woody fibers give way. Attached to the root are rootlets, not very plentiful, which bear a general resemblance to the main root, their central portion being woody and covered by a brown epidermis. The confusion that has existed regarding the roots of *Apocynum androsaemifolium* and *Apocynum cannabinum* results from the general resemblance of the plants, and from the fact that the names *bitter root* and *Indian hemp* have been applied indiscriminately to both species by herb gatherers and country people. *A. cannabinum* is quite plentiful in localities from which our (Cincinnati) market is supplied, while the *A. androsaemifolium* is scarce. This plant, likewise called *Dog's bane*, *Milkweed*, etc., is found growing in dry, sandy soils, and in the borders of woods from Maine to Florida, flowering from May to August; when any part of it is wounded, a milky juice exudes. The large, milky root is the medicinal portion, or rather its bark, which forms the greater part of it; it possesses an unpleasant, amarous taste. It yields its properties to alcohol, but especially to water. Age impairs its virtues.

Chemical Composition.—Zollickoffer states that it contains resin, caoutchouc, and mucus. Bigelow supposed it to contain volatile oil, soluble red coloring matter, extractive, and a body resembling caoutchouc. The bitter principle has been isolated as a semi-solid mass, and is thought to contain *apocynin*, and the glucoside, *apocynin* (see *Apocynum*).

Action, Medical Uses, and Dosage.—Emetic, diaphoretic, tonic, and laxative. When given with capsicum or opium its emetic action is checked, and with the latter drug diaphoresis is produced. It has been found very valuable in the treatment of *chronic hepatic affections*, and in conjunction with menispermum in *dyspepsia* and *amenorrhœa*. When it is required to promptly empty the stomach, without causing much nausea, or a relaxed condition of the muscular system, the powdered root may be given in doses of 40 to 60 grains. However, it is said to occasion a subsequent weakness or languor, from which the patient is some time in recovering. As a laxative, it is useful in cases of *constipation*, and in *hepatic derangements*. As a tonic, 10 or 20 grains may be given to stimulate the digestive apparatus, and thus effect a corresponding impression on the general system. As a diaphoretic it must be combined with opium, in the proportion of 1 grain of the latter to 40 of the former, and divided into three or four doses; however, as a diaphoretic it is inferior. Also reputed useful as an alterative in *rheumatism*, *scrofula*, and *syphilis*, having been much used in the first and last complaint by the American Indians. Its chief use, however, is in *dyspepsia* with constipation, and in *headache* with torpor of the bowels, as well as in *nervous headache* and *headache* due to sluggish venous capillary circulation of the brain. It is somewhat singular that it does not meet dropsical conditions like its relative, *Apocynum cannabinum*. Dose: Infusion (℞j to water Oj), 1 fluid drachm to 1 fluid ounce; fluid extract, 1 to 20 drops; tincture, 1 to 30 drops every 3 hours.

APOMORPHINÆ HYDROCHLORAS (U. S. P.)—APOMORPHINE HYDROCHLORATE.

FORMULA: $C_{17}H_{17}NO_2HCl$. MOLECULAR WEIGHT: 302.79.

"The hydrochlorate of an artificial alkaloid prepared from morphine or codeine. It should be kept in small, dark amber-colored vials"—(U. S. P.).

SYNONYM: *Hydrochlorate of apomorphine*.

Preparation.—The salt is produced by the abstraction of a molecule of water from the morphine employed—a process of dehydration. For this purpose place into a strong glass tube pure morphine (1 part) and hydrochloric acid (20 parts). The tube should be large enough so that the mixture fills but about one-fifteenth of its capacity, and the open end securely sealed. Enclose this tube in one of metal and heat for 3 hours at a temperature between 140° and 150° C. (284° and 302° F.), preferably in an oil-bath. After cooling, water is added to

the contents of the tube, and an excess of bicarbonate of sodium added. The precipitate is exhausted with chloroform or ether and the supernatant liquid poured off from the precipitate, which may be agitated with chloroform or ether to recover an additional amount of the salt. Hydrochloric acid, in very small amounts, is now cautiously added to the solution when crystals of apomorphine hydrochlorate are formed. Apomorphine should be rendered pure by recrystallizing it from boiling water, and afterward drying rapidly under a glass bell-jar over concentrated sulphuric acid, or upon layers of bibulous paper. Apomorphine may also be prepared by acting upon codeine with hydrochloric acid. This compound was first produced by Matthiessen and Wright in 1869.

Description and Tests.—The *U. S. P.* describes this salt as "minute, grayish-white, shining, acicular crystals, without odor, having a faintly bitter taste, and acquiring a greenish tint upon exposure to light and air. Soluble at 15° C. (59° F.), in about 45 parts of water, and about 45 parts of alcohol; very little soluble in ether or chloroform. When heated to near 100° C. (212° F.), the salt is decomposed, rapidly if in solution, slowly when dry. At 270° C. (518° F.) it fuses to a black mass, and, when ignited, it is consumed without leaving a residue. The salt is neutral to litmus paper. The crystals are colored blood-red to orange by nitric acid, transiently violet to light-brown by sulphuric acid, dark-purple to orange by a mixture of these acids. On shaking a few cubic centimeters of the saturated aqueous solution of the salt with a few small particles of manganese dioxide, the liquid acquires a green color, which is turned reddish-brown by adding some crystals of oxalic acid. If the oxalic acid be added to the solution first, and then a few small particles of manganese dioxide, the liquid will, upon agitation, assume a deep brownish-red color. Silver nitrate T.S. added to the aqueous solution of the salt throws down a white precipitate, insoluble in nitric acid, soon turning black by reduction to metallic silver, or instantly reduced by addition of ammonia water. Addition of sodium bicarbonate solution to the aqueous solution throws down the white, amorphous alkaloid, which soon turns green on exposure to air, and imparts a violet or blue color to chloroform, in which it is very soluble (difference from morphine). If the salt impart, at once, an emerald-green color to 100 parts of water on being shaken with it a few times in a test-tube, it should be rejected"—(*U. S. P.*).

When pure, the alkaloid, apomorphine, is an amorphous, white, or grayish-white powder, dissolving with considerable freedom in water, chloroform, ether, and benzol. After turning green by exposure to a moist atmosphere, it will dissolve with a blue tint in chloroform. With ferric chloride, an amethyst or rose-red hue is produced which serves to distinguish it from morphine, which, under like treatment, gives a blue coloration. Apomorphine salts are not readily soluble in water at ordinary temperatures, but dissolve more readily in acidulated solutions and warm water. On account of a change in properties, with the development of a green color upon exposure, solutions of apomorphine, or its salts, should only be prepared when needed for use.

Action, Medical Uses, and Dosage.—The action of this drug is exceedingly depressing, and death may result even from very small doses. The chief symptoms are pronounced sedation, giddiness, pallid surface, cold sweat, and profound collapse with unconsciousness. Usually, however, copious vomiting takes place, and the foregoing symptoms are then relieved. Sometimes, after vomiting, dangerous syncope may result. A middle-aged man, suffering from bronchitis, died in 7 minutes without vomiting, from $\frac{1}{15}$ grain hypodermatically. Deep sleep and disposition to faint sometimes follow when a disturbing dose has been administered. Owing to the fact that this agent induces a profuse, watery bronchial secretion, it is, unless in minute amounts, contraindicated in respiratory affections. However, in *croupal pneumonia* and *bronchitis*, minute doses ($\frac{1}{15}$ to $\frac{1}{10}$ grain) may improve a dry condition of the membranes when such a state is present. Care should be had in its use upon children. Attacks of *maniacal delirium*, *chorea*, *obstinate singultus*, *tetanus*, *rigidus uteri*, and *hystero-epilepsy* have been cut short with it administered hypodermatically. It is, however, a dangerous remedy. An emetic dose is said to very promptly relieve *hysteria*. Prof. Bloyer employs it in painful conditions of the stomach due to overloading that organ. By its prompt emetic effect in unloading the stomach, the painful attack

is cut short. The chief use, however, for this salt, is as an emetic when promptness is required in relieving the stomach of *poisons*. A $\frac{1}{16}$ or $\frac{1}{8}$ grain dose may be hypodermatically injected and vomiting almost immediately follows. This course is to be recommended in *poisoning by strychnine, carbolic acid, opium*, and its alkaloids, etc., and in *alcoholic intoxication*. Care should be exercised in its employment in the latter state. It has been used to expel *foreign bodies* from the cesophagus. The dose as an expectorant is $\frac{1}{16}$ to $\frac{1}{8}$ grain; as an emetic, by mouth, $\frac{1}{16}$ to $\frac{1}{8}$ grain; hypodermatically, $\frac{1}{16}$ to $\frac{1}{8}$ grain. The smaller doses, never exceeding $\frac{1}{16}$ grain, should be given to children. Only fresh preparations should be used.

Specific Indications and Uses.—To provoke prompt emesis in the early stage of alkaloidal and other cases of acute poisoning.

Related Salt.—**APOMORPHINE SULPHATE.** This product was obtained by Arppe, in 1845, by heating together, at a temperature as high as 150° C. (302° F.), sulphate of morphine in water, and sulphuric acid in excess. It forms a practically insoluble white salt, and was named by its discoverer, *sulphomorphid*, and given the formula $C_{17}H_{13}NSO_4$. Matthiessen and Wright, who first prepared hydrochlorate of apomorphine, proved it to be apomorphine sulphate.

AQUA (U. S. P.)—WATER.

FORMULA: H_2O . MOLECULAR WEIGHT: 17.96.

SYNONYM: *Hydrogen monoxide*.

"Natural water in its purest attainable state"—(U. S. P.).

Source, Description, and History.—"A colorless, limpid liquid, without odor or taste at ordinary temperatures, and remaining odorless while being heated to boiling"—(U. S. P.). Water is one of our most extensive pharmaceutical agents. The purest water obtainable is distilled water (see *Aqua Destillata*), which, when properly prepared in clean glass vessels, is colorless, transparent, scarcely compressible, tasteless, and odorless, with the assumed specific gravity 1, being the standard to which the specific gravities of liquids and solids are referred. It is the only admissible water for pharmacal and chemical tests, as the presence of organic or saline substances in it, may decompose the articles to be dissolved, or impair its solvent power. At a temperature of 0° C. (32° F.), or lower, it is converted into ice; boils at 100° C. (212° F.), and is converted into steam. Its crystallization into ice is accompanied with expansion, and the specific gravity of ice is 0.916; the volume of steam is about 1700 times more than that of water, and its specific gravity is 0.622. Water is perfectly neutral, exhibiting neither acid nor basic properties, though capable of combining with acid or basic anhydrides, thus developing acids and bases formerly and still incorrectly called hydrates. It likewise readily combines with many gaseous bodies, giving to them a fluid form. As a general rule, its solvent powers are increased by heat, especially in regard to solid bodies. It should always be kept in well-closed, green glass vessels. Pure water is formed by the combination of 2 volumes of hydrogen with 1 volume of oxygen, thus: $H_2 + O = H_2O$ or *hydrogen monoxide*. Water is never found naturally pure, differing in many respects according to its locality. It is generally distinguished as *Soft water*, *Hard water*, and *Mineral* or *Medicinal water*. For most ordinary purposes *soft waters* are preferred to the hard, and may be distinguished by the readiness with which they dissolve soap, notwithstanding they may contain considerable foreign matters. *Hard waters*, on the contrary, holding in solution salts of calcium or other earths, dissolve soap, but subsequently form insoluble compounds with the latter; these waters are unfit for internal use or household or pharmacal purposes. In this respect water is spoken of as having *temporary* and *permanent* hardness. The former takes into account the total amount of calcium and magnesium salts, including those that are precipitated by merely boiling the water (see *Tests*). Permanent hardness refers to those salts alone that remain in solution after boiling the water. The principle involved in the determination of the hardness of a water (by Clarke's process), is simply that the calcium and magnesium salts are precipitated from the water by means of an alcoholic potassium-soap solution, of known strength, previously standardized by means of a calcium chloride solution of definite strength. When all alkaline earths are thus precipitated from the water, a slight excess of the soap

solution, upon shaking the water, will cause a heavy froth which remains permanent for at least 5 minutes. The old English degree of hardness was defined as the number of grains of calcium carbonate in 1 gallon of water; by more modern usage, 1 part of calcium oxide (CaO) (German usage) or calcium carbonate (CaCO_3) (French usage), in 100,000 parts of water, is called 1 degree of hardness. Water is distinguished by its origin as follows:

RAIN WATER (*Aqua pluvialis*) and **SNOW WATER** (*Aqua nivalis*), when collected so as to prevent accidental impurities, are the purest waters to be had naturally. They are generally impregnated with the soluble matters in the atmosphere, which vary in different localities, the most common impurities being carbonic acid gas, carbonate of ammonium, chloride of sodium, organic and suspended mineral substances; during a thunder-storm traces of nitric acid and nitrates are said to be likewise present. In collecting rain water, the first that falls should be rejected; if from the tops of houses, 2 or 3 hours of continuous shower will wash off any objectionable impurities, and the water will run clear and transparent; if from an open space at a distance from dwellings, it may be permitted to fall an hour or so before attempting to collect it. To obtain it as pure as possible, it should be filtered, boiled, and again filtered. No pure water should ever be used that comes in contact with new lead—for the lead becomes oxidized by the oxygen of the water, which oxide is converted into a carbonate by the action of the carbonic acid gas derived from the air, and the water thus containing lead may produce the poisonous effects of the metal upon the system. Hard water attacks lead less readily than soft water.

Snow water is said to be richer in oxygen than other water, and is generally free from the atmospheric gaseous impurities found in rain water; it quenches thirst, while snow, not melted, augments it. The opinion at one time entertained that the use of snow water disposed to goitre is undoubtedly an erroneous one, as the disease not only occurs where snow is never seen, but is unknown in many sections of mountainous countries where the water employed is chiefly that supplied by the melting of the snow which covers the mountains. Rain and snow waters, collected with a degree of care, are applicable to every domestic purpose, as well as to many chemical and pharmacal processes.

SPRING WATER (*Aqua fontana*) is that which springs from the earth, free from large amounts of carbonic acid, or salts, and not possessing elevated temperatures; it is the general beverage of mankind, and is applicable to all domestic purposes. Its quality varies according to the nature of the soil in its vicinity; those springs arising from trap rocks, sandstones, transition, and primitive rocks, are purest; those from alluvial strata, limestone, and coal formations, are the least pure. All, however, contain variable traces of the salts of calcium, sodium, or magnesium, according to the character of the soil through which they flow.

WELL WATER (*Aqua puteana*) very much resembles spring water in its qualities, its purity being somewhat governed by the depth at which it is procured, and its daily flow. The Artesian wells usually supply a very pure water. Nitrates and organic impurities have been found in the well water of cities, as might naturally be expected from the impurities of their soils.

RIVER WATER (*Aqua fluvialis*), especially when passing through alluvial countries, and near great cities, contains suspended in it more or less earthy and organic impurities of a vegeto-animal origin, which lessen its clearness, but in a short time it becomes purified of these by deposition during its downward course. In countries where the rivers pass chiefly over primitive rocks, the waters are found to be almost perfectly pure. When moderately pure, it is fit for all ordinary purposes, though if it contains much organic matters, it is apt to occasion dysentery, and other affections of the bowels, and then becomes inadmissible in medicine.

MARSH WATER (*Aqua ex palude*), on account of its stagnation and repletion with putrescent matters, is altogether unfit for domestic or therapeutical use. This water contains among other impurities animalcules, and microscopic vegetation; although these are met with in running and clear waters in which there is considerable vegetable growth. But they are absent in spring and well waters, and most of the river waters supplied for domestic purposes. There is no doubt but that the drinking of water containing shreds or filaments of cryptogamous

plants, has occasioned sickness and even death. River and lake water (*Aqua ex lacu*) should always be filtered or boiled before using as a beverage.

AQUÆ MINERALES.—(For *Mineral Waters* see *Aquæ Minerales*).

Impurities in Common Water, and Their Detection.—From 1 to 3 parts in 10,000, or even slightly more of solid matter (*U. S. P.* permits the limit of 5), if it be composed principally of sodium chloride and calcium carbonate, is permissible in good, wholesome drinking water. It may also contain carbon dioxide in the proportion of 1 volume in 100 volumes of water. The most objectionable impurities are ammonia and organic matter, the presence of which indicate contamination of the water with decaying animal and vegetable tissues. The pharmacopœial tests for *organic matter* and limit of ammonia are subsequently mentioned. Water contaminated with sewage or other nitrogenous impurities, contains ammonia, 0.10 Gm. of which in 1,000,000 renders it unfit for drinking purposes. An outline of the quantitative analysis of water, on which subject there are several well-known special works extant (*e. g.*, Wanklyn, Frankland, Miller, etc.), can not be herein considered. The *U. S. P.* gives the following criteria for the purity of water:

"A colorless, limpid liquid, without odor or taste at ordinary temperatures, and remaining odorless while being heated to boiling. Water should be perfectly neutral to litmus paper, and its transparency should not be affected, nor should any color be imparted to it, by hydrogen sulphide T.S., or ammonium sulphide T.S. (absence of metallic impurities). It should also remain unaffected by mercuric chloride T.S. (limit of ammonia). On evaporating 1000 Cc. of water on a water-bath, it should not leave a residue weighing more than 0.5 Gm. (limit of soluble salts), and this residue, when ignited, should not carbonize, nor evolve ammoniacal or acid vapors. If 200 Cc. of water be acidulated with hydrochloric acid and heated to boiling, and 0.5 Cc. of barium chloride T.S. added, the liquid, cooled and filtered, should give no further precipitate on the addition of a few drops of barium chloride T.S., even on standing (limit of sulphates). If 200 Cc. of water be acidulated with nitric acid, and 0.5 Cc. of decinormal silver nitrate V.S. be added, the filtered liquid should not be affected by the subsequent addition of a few drops of silver nitrate T.S. (limit of chlorides). If 5 Cc. of water mixed with a few drops of diphenylamine T.S. be carefully poured upon about 2 Cc. of sulphuric acid, free from nitrose, contained in a test-tube, so as to form a separate layer, no blue color should be formed at the line of contact of the two liquids (limit of nitrates). If 100 Cc. of water be acidulated with diluted sulphuric acid free from nitrose, and a few drops of zinc-iodide-starch T.S. subsequently added, the liquid should not at once assume a blue or violet color (absence of nitrites). On heating 100 Cc. of water, acidulated with 10 Cc. of diluted sulphuric acid, to boiling, and subsequently adding 0.5 Cc. of decinormal potassium permanganate V.S., the color of the liquid should not be completely destroyed by boiling it for 10 minutes (limit of organic and other oxidizable matters)"—(*U. S. P.*).

Calcium salts in solution are recognized by being precipitated with ammonium oxalate T.S. Free carbonic acid gas in the water may be recognized by the addition of an excess of lime water, whereby insoluble calcium carbonate falls. If lime water is cautiously added in an amount sufficient to combine with only half, or less, of the carbonic acid gas present, the remainder of this gas will keep the calcium carbonate in solution, forming bicarbonate of calcium. This, upon boiling, is decomposed into carbonic acid gas and insoluble calcium carbonate. On this principle calcium carbonate is dissolved by natural water with the aid of carbonic acid gas, and deposited from this solution when its solvent, carbonic acid gas, is expelled by spontaneous evaporation. Organic matter may be recognized, beside the test previously indicated, by evaporating to dryness and igniting, whereby charring takes place to a greater or less degree. Organic matter also will reduce gold from a few drops of chloride of gold solution that have been added to about 1 or 2 ounces of the water to be examined. The reduction of the gold is manifested by a violet or blue coloration of the originally slightly yellow liquid. The presence of ammonia in water, beside the test indicated above, is also detected by Nessler's reagent (see *List of Reagents*). For the detection of nitrites in water there are several delicate tests. The following test, originally devised

by Griess, will detect 1 part of N_2O_5 in a thousand million parts of water. It is carried out as follows: Add to the liquid to be tested some pure sulphuric acid, then a few drops of a solution of sulphanilic acid ($C_6H_5NH_2SO_3H$) and about 10 minutes afterward a few drops of naphthylamin sulphate ($C_{10}H_7NH_2HSO_4$). If a nitrite is present, an intense red coloration is developed after a short while, due to the formation of an azo-dye (see *Aniline*).

Action, Medical History, and Uses.—Lack of space permits of but a brief resumé of the physiological and therapeutical actions of water; for further elucidation the reader is referred to special works on *HYDROTHERAPY*. The treatment of disease by means of water is by no means modern, as there is ample evidence of its employment by Hippocrates, and later by Galen, Avicenna, and Celsus. In more modern times its importance in therapy was recognized by Sir John Floyer and Dr. Baynard (England) who employed baths in chronic affections, and particularly by Dr. James Currie, of Liverpool (1797), who published a work upon the uses of cold and warm water in fevers and other diseases. His views, given to the world at a time when even a drink of cold water was rigidly denied the fever patient, naturally met with violent opposition from a large portion of the medical fraternity, though his sensible doctrines and practices met with considerable favor in some quarters. Though affusions were largely recommended by him, an important feature of his practice consisted in the administration of cold drinks in fevers. Later, however, a renewed impetus was given the water treatment through the discoveries of Vincenz Priessnitz, the peasant-farmer of Silesia. Having sprained his wrist, Priessnitz resorted to affusions of cold water, followed by the *Umschlag* (wet bandage). Priessnitz was but 13 years of age, but so successful was his treatment that in subsequent injuries to himself he resorted to similar treatment. As in each instance, an eruption was produced by the constant wet application, he conceived a theory that it was indicative of impure blood, and this subsequently led him to adopt a "humoral" pathology, and to declare that all morbid matters (acid humors) were eliminated by "crisis" (the eruption). His treatment was extended to the ulcers, injuries, etc., of his neighbors, and finally, in 1826, he opened an establishment for the treatment of disease by means of water, and his fame became world-wide. Though lacking in scientific knowledge, and entertaining many mistaken hygienic views, yet his treatment, coupled with improved habits of living and eating, and plenty of fresh air and exercise, proved eminently successful. In 1844 the treatment was introduced into New York City. While undoubtedly much credit is due Currie as the originator of hydropathy as now practiced, its establishment as a therapeutic measure is due to the persistency and the success of the unlettered Priessnitz in pursuing his novel methods of treatment. The treatment, as pursued by Priessnitz and his followers, is that commonly known as *Hydropathy*; as now employed it is known as *Hydrotherapy*. Owing to the unscientific and injudicious methods of the followers of Priessnitz, his methods gradually fell into disrepute, and in medical circles but little more was heard of it until Brand, of Stettin (1861), gave his scientific reports of the use of cold baths in typhoid fever; since which time the treatment of fevers by means of baths has been by modifications of Brand's method.

In recent years much importance has been attached by some physicians to the cold bath in *fevers*, particularly those of a typhoid type. According to its advocates, it is contraindicated chiefly by intestinal hemorrhages, which it appears to favor, and by peritonitis. Brand's method is to immerse the patient, wrapped in a sheet and his head first wetted, into a large bath of water at 15.5° to 21.1° C. (60° to 70° F.), whenever the patient's temperature reaches 39° C. (102.5° F.). The body is briskly rubbed through the sheet, and stimulation resorted to if shock and cyanosis seem to demand it. After remaining in the bath for 15 or 20 minutes, the patient is removed from the bath, the wet sheet quickly replaced by a dry one, and the patient placed in bed, covered with a light blanket. The rectal temperature is taken immediately after immersion and again in 45 minutes. When the temperature again reaches 102.5° F. or over, the bath is repeated, and so on indefinitely. Ziemssen's method consists in employing the bath at about 36.6° C. (98° F.), and cooling the water during the immersion, by means of ice, to 26.6° C. (80° F.), 15.5° C. (60° F.), or even 4.4° C.

(40° F.), according to effect upon temperature. After the bath, the patient is dried, placed in bed, and covered with blankets. The temperature is taken per rectum. Ziemssen, Immerman, and others, administered the baths at regular intervals; others have modified Ziemssen's method by employing the bath only as the rise of temperature seemed to demand it. Still others, as Osler, have recommended and practiced baths at 29.4° to 32.2° C. (85° to 90° F.) and cooling to 21.1° C. (70° F.). The claims made for the cold bath, and particularly by Brand's method, are: Reduction of temperature, control of muscular twitchings, brightening of the intellect, soothing of the nervous system, the induction of sleep, increased heart-power, improvement of the skin, and low mortality. Ziemssen's method is said to give less shock, and Osler's method is asserted to be less effective in reducing temperature (see also paper by G. S. Harrington, M. D., in *N. Y. Med. Times*, Aug., 1897, p. 239).

The use of the bath as above described, has not found favor in the Eclectic school. The medical treatment of fevers, as pursued so successfully by our physicians, and with results that have gained fame for the methods of our practice, has been such as to beget an unwillingness to abandon successful and pleasant methods for a procedure at best uncertain, and extremely uncomfortable and annoying to the patient. Briefly, the following resumé will indicate some of the uses of hot and cold water, both internally and externally.

As a remedial agent, apart from its natural necessitous use, water internally is a tonic, diuretic, or sudorific, according to its mode of administration. Small quantities, taken cold, between 7.2° to 15.5° C. (45° to 60° F.), and occasionally repeated, act as a tonic; in larger doses it produces diuresis and diaphoresis, the latter effect more especially, if the patient be kept warmly covered; and it is extensively used for this purpose in many acute diseases. Warm water, of a temperature varying from 18.3° to 37.7° C. (65° to 100° F.), and especially when taken in large quantities, will usually produce sickness and vomiting, and its continued daily use in small quantities will impair the tone of the stomach. Cold water, from 1.1° to 7.2° C. (30° to 45° F.) is a grateful drink, more particularly to fever patients, allaying thirst, moderating the fever, often producing sleep and relief from restlessness, and is sufficient, unaided by other means, to effect a rapid solution of the disease, in many instances. It should never be withheld from patients laboring under *febrile* or *inflammatory* complaints, who crave it. During the operation of a vegetable emetic, cool water at 15.5° C. (60° F.), is more agreeable, and fully as beneficial in assisting emesis, as warm. Cold drinks are very useful in *chronic constipation*, a glass of cold water being drunk before breakfast. With some, warm water acts best as a laxative. Owing to its diuretic effect, an abundance of water assists in washing out the kidneys in *acute desquamative nephritis*. Water, in judicious amounts, may be administered in *acute gastric inflammations*. Ice held in the mouth frequently aids in subduing *tonsillitis*. The ingestion of warm water is frequently useful in *gastralgia*, *dyspepsia*, *chronic diarrhoea*, *gout*, *rheumatism*, and in many *chronic skin affections*.

The effects of water employed externally, depend upon its temperature. The cold bath acts according to its degree of cold, the manner in which it is used, and the peculiar state of the body at the time. When below 10° C. (50° F.), the bath is considered very cold. The primary effects of a cold bath constitute the *shock*—its secondary effects, the *glow*, or reaction. The immediate effects of a cold bath are a sensation of cold, which gradually ceases, and is succeeded by numbness, the skin becomes pale, and covered with *cutis anserina*, there is shivering, with quick and irregular respiration, and a contraction of the cutaneous vessels, as well as of the volume of the body. If the immersion be continued, the pulse becomes slow and small, drowsiness and cramps come on, the heat of the body diminishes rapidly, and finally syncope and death occur. A cold bath is usually taken for its stimulating and tonic influence, and hence, should not be below 10° C. (50° F.), nor above 23.8° C. (75° F.), and the immersion should be temporary. Reaction speedily follows, capillary circulation is re-established, a glow is felt, perspiration comes on, the pulse becomes full and frequent, and the whole system feels invigorated. Delicate or weakly persons should not take a cold bath. It is a common opinion that immersion in cold water is dangerous when the body is heated by exercise or other exertion; and hence it is customary

with bathers to wait until they become cool. The first is an erroneous opinion; the second an injurious act. Cold water abstracts heat from the body, first becoming sedative, and then, if immersion be not too prolonged, it acts secondarily as a stimulant. Under the cold bath, properly employed, the body gains in weight.

Warm water, according to its temperature, affects the system in varying degrees, but the quality of the action is similar, no matter whether the bath be warm or hot. A sense of warmth is first experienced, followed by increased vascular activity of the skin, the latter becoming red. Respiration is quickened, and the heart action increased, though the vessels lose tension. The body takes on heat, the radiation of which is prevented, and the temperature amounting in some persons, if the bath be hot, almost to a fever. The renal secretions are diminished, while those of the skin and lungs are augmented, through which the body loses weight. Unpleasant præcordial oppression, and a feeling of fullness in the head, with a sense of distension, dizziness, and faintness, are among its effects. If too prolonged, or too high in temperature, the hot bath may produce bleeding at the nose and lungs, cerebral congestion, or apoplexy. They are contra-indicated where the cerebral vessels are known to be diseased. The hot bath is somewhat similar in its effects to the vapor, but is apt to prove dangerous in some constitutions. Dr. J. Chapman states that heat along the spine lessens the general circulation, overcomes congestion in all parts of the body, lessens fever, checks hemorrhage, and diminishes or suspends the menses.

Externally, water is frequently applied as a sedative in local inflammations, as *quinsies, sore throats, ophthalmia, sprains and contusions*, and as a means of restraining hemorrhage. Cloths wet with cold water and applied to the abdomen, have relieved severe pain in the bowels, retention of urine, etc. The cold dash or douche, has been successfully employed in *delirium tremens, apoplexy, tetanus, hysteria, convulsions, obstinate constipation, congestive, bilious, and typhoid fevers*. The wet sheet is much used to allay febrile and inflammatory conditions, and to promote diaphoresis. As an injection, it has been efficient in *habitual constipation*, and excessive tympanitic distension, as well as in *dysentery*. Applied warm it is an excellent application to *erysipelatous inflammations*. Ice and iced water, as local applications, are said to be very useful in *burns and scalds*; also in many *cerebral affections*. Prof. C. E. Brown-Sequard considered the application of cold to the spinal column to produce a contraction of blood-vessels by a reflex action, but if this action be very powerful, it will be followed by exhaustion and dilatation of the blood-vessels, and an actual increase of the amount of blood circulated in the cord. Dr. J. Chapman considered that ice applied upon the spinal column augments the general circulation, checks the *cramp* of voluntary and involuntary muscles, restrains the *sickness of pregnancy*, cures *sea-sickness*, and promotes menstruation. He stated to have used it successfully in *epilepsy* and other *convulsive affections*, in *paralysis, tetanus*, and in *cerebro-spinal fever*. His views have been published and are worthy of consideration. Locally, both cold and warm water are very useful in *surgical procedures*, particularly in *sprains, bruises, contusions*, etc., and the local warm bath is particularly valued in *lacerated wounds and contusions*. The application of cold water, snow or ice to *frost-bites* is well known.

The following are the temperatures at which baths are usually applied :

Water, cold.....	10°	to	23.8° C.	(50° to 75° F.).
" temperate.....	23.8	to	29.4 C.	(75 to 85 F.).
" tepid.....	29.4	to	33.3 C.	(85 to 92 F.).
" warm.....	33.3	to	36.6 C.	(92 to 98 F.).
" hot.....	36.6	to	44.4 C.	(98 to 112 F.).
Vapor if breathed, tepid.....	32.2	to	37.7 C.	(90 to 100 F.).
" " warm.....	37.7	to	43.3 C.	(100 to 110 F.).
" " hot.....	43.3	to	54.4 C.	(110 to 130 F.).
" if not breathed, tepid.....	35.5	to	41.1 C.	(96 to 106 F.).
" " warm.....	41.1	to	48.8 C.	(106 to 120 F.).
" " hot.....	48.8	to	71.1 C.	(120 to 160 F.).
Hot air, as a sudorific.....	29.4	to	37.7 C.	(85 to 100 F.).
" " as a stimulant.....	37.7	to	54.4 C.	(100 to 130 F.).

The VAPOR-BATH increases the action of the capillary vessels, causing excessive diaphoresis; it renders the skin pliable, relieves tension and rigidity of the

joints, and may be usefully employed in *rheumatism*, *cutaneous affections*, *gout*, *profuse sweating* from cutaneous debility, tardy or imperfect eruptions of the *exanthemata*, *paralysis*, *dropsy*, etc. It is of particular value in *nephritis*, and, directed into the mouth, in *membranous croup*. The Russian bath is a form of vapor bath in which the patient is subjected to the vapor of water at 35° to 43.3° C. (95° to 110° F.). It should not be borne longer than a quarter of an hour, and the bath should be followed by a cold bath or the dashing of cold water over the body, associated with friction.

The vapor bath may be conveniently given, and in a very simple manner, by placing the patient between blankets, on a bed previously protected by a rubber sheet, and tucking the covering well around the head and shoulders, and down at the sides of the bed. Then, by means of rubber tubing, conduct the steam from a partially filled tea-kettle of boiling water, kept hot by placing the kettle upon an oil or other heating apparatus, into the space between the blankets. Care should be had that the jet of steam does not come in direct contact with the flesh. If the patient is able to sit up, a low stool may be utilized, and the patient covered with a blanket under which the jet of steam may be directed. Fresh lime is sometimes resorted to to raise a vapor, and is particularly of value in *diphtheria* and *croup*. The *spirit vapor bath* is referred to elsewhere.

The **TEPID-BATH** (29.4° to 33.3° C. [85° to 92° F.]) is useful in softening and removing the broken-down epithelium, as well as the sebaceous and sudoriferous secretions. It does not appreciably reduce temperature, and no reaction follows.

The **WARM-BATH** (33.3° to 36.6° C. [92° to 98° F.]) relaxes the system, lessens the activity of the circulatory and respiratory organs, ultimately somewhat diminishes the temperature of the body, and tends to tranquilize and occasion somnolency. It is useful in *spasms* and *convulsions of children*, *retention of urine*, *nephritic pains*, etc., and occasionally through its secondary effects in *high inflammatory* and *febrile diseases*, it will frequently prove advantageous. It should not be used in cerebral and pulmonary affections.

The **TEPID OR WARM SPONGE-BATH** is exceedingly useful in many *febrile conditions*, for when employed in this manner, the skin is well relaxed, and the radiation of heat is not prevented as by immersion. There can be no doubt but that sponging the head *constantly* with warm water, drawing the sponge back and forth, and at the same time fanning the parts, is far more effective and safe in cases of *insolation*, *cerebro-spinal inflammations*, etc., than is the local application of cold water or ice, which probably does little more than chill the surface.

The **COLD SPONGE-BATH** (12.7° to 26.6° C. [55° to 80° F.]) is frequently employed by some to reduce temperature and allay nervous excitement; the anterior surface of the body being first sponged, and then the dorsum. Dr. G. S. Harrington (*N. Y. Med. Times*, 1897) advises the addition of 20 to 35 per cent of alcohol to increase the antipyretic value of the bath. The patient is then to be covered with a light sheet and blanket.

Cold water may also be used by affusion, shower-bath, or douche, and will be found tonic, stimulant, or sedative, according to its temperature, the length of time it is used, and the state of the body.

In addition to the above uses of water, it has likewise other employments, as follows:

The **WET-SHEET PACKING**, or *Lein Tuch* of the Germans. A mattress of cotton, hair, or straw, has spread over it three or four large, thick comfortables, and over these one or two soft flannels. A linen sheet, having been previously dipped in cold water, or for very delicate persons in tepid or even warm water, is lightly wrung out, so as not to drip, and spread over the whole, having under it one or two pillows for the head. The patient is made to lie upon these on his back, and is quickly and snugly enveloped in the wet sheet, over which is placed the flannels and blankets, or a light feather bed may be thrown over the top, in case comfortables are not plenty. Care should always be taken to turn the clothing snugly and smoothly around the feet and neck; and if the feet remain cold, bottles of hot water should be placed to them. Headache is prevented or removed by the application of cold wet cloths applied to the head.

The time for remaining thus "packed" varies in different cases, averaging

from half an hour to an hour, depending on the effect; the body should become comfortably warm before being removed. A disagreeable sensation of cold is first experienced, which is soon followed by a pleasurable warmth over the whole surface, and sometimes copious perspiration, though this last is not always indicated. On coming out of the "pack," the plunge, the douche, rubbing wet sheet, or towel washing, are to be employed, as the case may require. If the patient experiences a chill after coming out, a thorough rubbing, followed by 15 or 20 minutes' dry packing, will usually obviate all injurious consequences. The process of packing should never be continued so long as to cause headache, languor, muscular debility or giddiness.

This is said to act as a sedative, reducing the heat of the body, and excessive arterial action, and as an alterative, correcting morbid secretions, and restoring healthy ones. In *fevers* and all *acute inflammatory disorders*, it may frequently be renewed according to the degree of fever or inflammation, until the temperature and circulation are reduced to the natural standard, and the skin becomes soft and perspirable. Much sweating is not usually to be desired. In *chronic diseases*, it removes internal congestions, develops external circulation, produces a healthy condition of the skin, and may be used in many forms of this class of maladies. If carelessly attended to the wet sheet may give rise to serious difficulties.

When the wet sheet is applied to the trunk of the body only, as in cases of feeble persons, where there is not sufficient vitality for the whole sheet, or for other purposes, it is termed the "HALF-PACK" SHEET.

The RUBBING WET-SHEET is a large sheet dipped in water, and wrung out so as not to drip. It is then suddenly thrown around the patient's body, enveloping him closely from the neck to the feet, and the body is then rubbed for about 5 minutes by the hands of the attendants on the outside of the sheet. It is to be followed by rubbing with dry towels. This produces a strong and general determination to the whole surface, and is applicable in all cases where a strong determination is desired from internal organs or surfaces to the skin. It will be found valuable in the early stages of *bowel complaints, diarrhoea, dysentery, colic, fevers, etc.*; it is likewise useful for *exhaustion* following mental exertion, many forms of *insanity, delirium tremens, night-sweats, wakefulness, nightmare, etc.* When the sheet is employed drippingly wet (*the dripping sheet*), a large tub or pan is necessary for the patient to stand in, to avoid wetting the floor.

The DOUCHE is the application of a stream of cold, tepid, or warm water, from a greater or lesser height, and continued for a time indicated by its effects. The force of the stream and time of application should be carefully adapted to the strength of the patient. Very nervous persons, and those subject to determinations to the brain, should resort to it with extreme caution. A strong douche should never be applied to the head, nor should it be long continued on any one spot along the vertebral column. A douche may be vertical, oblique, horizontal, or ascending. The most common are in perpendicular streams 1 or 2 inches in diameter. Its effect is to arouse the activity of the absorbent system, and is hence very useful in *gout, rheumatism, paralysis, chronic enlargements of the viscera, tumors, etc.* The ascending douche will be found beneficial in *piles, uterine displacements, prolapsus ani, constipation* from debility, *chronic enlargement of the prostate gland, impotency, etc.* The stream may be $\frac{1}{2}$ to 1 inch, and should not be forcible enough to cause absolute pain nor serious inconvenience. Warm-water douches are for the purposes of producing relaxation of the muscles of the part acted upon, and are hence useful in *rigidity of the muscles, painful swellings, chronic inflammation of the joints, neuralgia, spasmodic and bilious colic, retention of urine, amenorrhœa, uterine rigidity, leucorrhœa, metritis, renal colic, etc.* In some cases it should be followed by a momentary cold dash. Prof. Brown-Sequard considered the *Cold douche* or *Cold shower bath*, useful in *white softening and reflex paraplegia*; and the *Hot douche* (37.7° C.) [100° F.], when applied to the spinal column over the painful part, very efficient in *congestion or inflammation of the cord*, but injurious in *white softening and reflex paraplegia*.

The HIP or SITZ-BATH is a common tub, in which the patient sits so as to have the water cover the hips and lower parts of the abdomen. A vessel made for the purpose, with a back to rest against, is more convenient. The water may be of any temperature, and the time of application varies from 5 to 30 minutes.

According to its application it is tonic, derivative, or sedative. Tonic when applied from 5 to 15 minutes; derivative when extended from 15 to 30 minutes; and sedative according to its effects. Derivative hip baths should not be carried to the point of producing paleness or lividity of the lips, shiverings, nausea, faintness, or headache, and according to the effect desired, and the coldness, torpor, and debility of the patient, indicate that the quantity of water should be lessened, or its temperature elevated. It is useful in *debility, irregularity, obstruction,* and *torpor* of the organs of the pelvis and lower part of the abdomen. A blanket is generally thrown around the patient during this bath.

The SHALLOW-BATH is a circular, or oval tub, raised about 12 inches from the floor, and with water in it from 4 to 6 inches deep. The patient sits in this, while the attendant sprinkles his head, and rubs his chest, abdomen, and back. It may be employed from 1 to 30 minutes, and should be followed by a good, dry rubbing. It is used at a temperature from 15.5° to 23.8° C. (60° to 75° F.), and is excellent in *cutaneous affections*, and other cases where a mild derivative, or moderately sedative influence is desired.

The PLUNGE-BATH may be any vessel or place, the water being from 12.7° to 18.3° C. (55° to 65° F.), which will allow the patient to plunge into it, head or feet foremost as he fancies, or to quickly immerse the whole body up to the neck. The time for remaining in it varies from a few seconds to 2 or 3 minutes, or in *high fever*, to 10 or 15 minutes. It is generally taken after the sweating process, and after the wet sheet, when the patient can bear the exertion; in these cases the sheet is not to be removed until at the plunge. It is very useful in all *febrile* and *chronic affections*, but should be employed with care, or avoided altogether in consumptive and dropsical patients, and those laboring under organic diseases of the heart.

These are the principal applications of water in practice; yet there are several others of a useful character, as the *Foot-bath*, the *Head-bath*, the *Shower-bath*, etc., the modes of application of which are generally well understood, as well as their effects. Cold water may likewise be used in form of a *bandage* or *girdle*, by applying one or more folds of linen wet in cold water, to the part affected, or around the abdomen, and covering it with a dry cloth or other material to retain the heat. The *wet girdle* or *abdominal wrapper* or *compress*, is applied around the abdomen in all acute diseases of the abdominal viscera. The *bandages* are applied *warm* or *cold*, according to the indications they are intended to fulfil. The application of hot water by means of wetted cloths laid upon the parts, is very effective in painful conditions, as in *dysmenorrhœa*, various forms of *colic*, *rheumatism*, and *neuralgia*, and to *inflammatory swellings*. The *rubber water bottle* is an excellent apparatus for the application of moist heat.

AQUÆ MEDICATÆ.—MEDICATED WATERS.

These consist of water holding in solution some medicinal or aromatic principles, as certain gases, volatile oils etc. Heretofore those waters which contained a portion of the aroma of certain plants, were procured by distilling water from either the fresh or dry herb; the principal portion of the volatile oil which collected on the top of the distillate upon standing, was removed, a sufficient amount being retained by the water to render it of the taste and odor of the plant. But such distilled waters are very apt to become spoiled, unless great care be taken to redistill them from time to time, or add to them some preservative material which is frequently an undesirable addition. It has, therefore, been found the best method to triturate the essential oil itself with certain substances in the water, which so minutely divide the former as to render it more soluble in the latter, as carbonate of magnesium, pumice stone, finely powdered glass or silica, etc., which yield a clear and permanent solution after being filtered through paper. Carbonate of magnesium was, previous to 1880, the medium more commonly employed in this country. The *U. S. P.* now directs precipitated calcium phosphate. As ordinary water contains several agents which may decompose or ultimately destroy the aromatic virtues imparted to it by the above method, it is of much importance that distilled water only be always used. T. B.

Groves succeeded in recovering volatile oils from their watery solutions, by first adding to them olive oil, and then saponifying with potash. The soap thus formed, when decomposed by an acid, liberates the mixed oils, from which the aromatic portions may be separated by shaking with alcohol (*Pharm. Jour. and Trans.*, V. 347, Feb., 1864).

Medicated waters have been made by adding to a few pounds of the leaves or flowers of the article required, 6 or 7 fluid ounces of proof-spirit, and 2 gallons of water; from which 1 gallon is distilled. In this way was formerly obtained nearly all of these preparations, but the processes given below are now esteemed the best. *Aqua Aurantii Florum*, orange-flower water, *Aqua Fœniculi*, fennel water, *Aqua Menthæ Piperitæ*, peppermint water, *Aqua Menthæ Viridis*, spearmint water, together with several others, may be procured from the plants or flowers, by the mode of distillation just referred to. The *U. S. P.* of 1880, directed the preparation of several of the medicated waters prepared from oils by adding to cotton a few drops at a time of the desired oil, carefully picking the cotton apart after each addition, after which the cotton was packed firmly in a conical percolator, and upon it distilled water was poured until the percolate measured 1000 parts. By this method it was found that either not enough of the oil was taken up by the water, or else free globules of oil passed through into the percolate, thus rendering it of uncertain strength. This method has been abolished. The objection to the use of magnesium carbonate, which was formerly employed in making these waters also, is that the salt itself is slightly soluble in water, so that when a substance like silver nitrate was directed to be dissolved in such a water, a precipitate of silver carbonate was thrown down. It has been replaced by precipitated calcium phosphate.

AQUA ACIDI CARBONICI.—CARBONIC ACID WATER.

SYNONYMS: *Soda water*, *Mineral water*, *Artificial Seltzer water*, *Aqua carbonica*.

Preparation.—This is prepared by saturating water under pressure with carbonic acid gas (see *Acidum Carbonicum*), generated by the action of diluted sulphuric acid on pulverized marble by means of an apparatus manufactured for the purpose. Five or six volumes of gas may thus be condensed in 1 volume of water.

History and Description.—At the ordinary temperature and pressure of the atmosphere, 1 volume of water absorbs 1 volume of carbonic acid gas, and acquires a specific gravity of 1.0018. By doubling the pressure, the quantity of gas absorbed by the water is doubled, and so on for other degrees of pressure; for, according to Henry's law, the quantity of gas forced into the water is directly as the pressure (P.). Thus, for water to absorb 5 times its bulk of this gas, a pressure of 5 atmospheres must be used.

The "soda water" of commerce, the well-known summer beverage, is merely a carbonic acid water, rendered more palatable by the use of some aromatic or agreeable syrup; when the carbonated water and syrup are mixed and bottled, it is then known by the name of "mineral water." Water containing carbonic acid gas is very effervescent, has a pleasant, tingling, slightly acidulous taste, and an acid reaction. The vessels containing it should be strong, and perfectly airtight, and kept in a cold place, otherwise the gas will escape, and the water lose its sparkling activity. Too much care can not be taken to avoid metallic impurities, especially lead, which should not be used at all where the carbonic acid water can come in contact with it; the pipes leading from the fountain should be made either of block tin or gutta-percha. The fountain containing this water, if made of copper, should be well lined with tin, and should be carefully examined every season before using it. The glass-lined iron fountains are preferable. Ammonium sulphide or hydrogen sulphide should not be discolored by carbonic acid water.

Action and Medical Uses.—Carbonic acid water is a refreshing, refrigerant beverage, useful to allay thirst, check nausea, and promote diuresis. It may be used in fevers, inflammatory diseases, chronic inflammation of the stomach, vomiting of pregnant females, etc.; and may be taken 3 or 4 times daily, in doses of from 3 to 6 fluid ounces.

AQUA AMMONIÆ (U. S. P.)—AMMONIA WATER.

"An aqueous solution of Ammonia ($\text{NH}_3=17.01$) containing 10 per cent, by weight, of the gas. Ammonia water should be kept in glass-stoppered bottles, in a cool place"—(U. S. P.).

SYNONYMS: *Liquor ammoniæ*, *Solution of ammonia*.

Preparation.—"Take of ammonium chloride, 13 ounces; quicklime, 13 ounces; water, $7\frac{1}{2}$ fluid ounces; distilled water, 12 fluid ounces. Slake the lime with the water, cover it up till it cools, triturate it well and quickly with the chloride of ammonium previously in fine powder, and put the mixture into a glass retort, to which is attached a receiver with a safety-tube. Connect with the receiver a bottle also provided with a safety-tube; and containing 4 ounces of the distilled water, but capable of holding twice as much. Connect this bottle with another loosely corked, and containing the remaining 8 ounces of distilled water. The communicating tubes must descend to the bottom of the bottles at the further end from the retort; and the receiver and bottles must be kept cool by snow, ice, or a running stream of cold water. Apply to the retort a gradually increasing heat till gas ceases to be evolved; remove the retort, cork up the aperture in the receiver where it is connected with the retort, and apply to the receiver a gentle and gradually increasing heat, to drive over as much of the gas in the liquid contained in it, but as little of the water as possible. Should the liquid in the last bottle not have the density of 0.960, reduce it with some of the stronger aqua ammoniæ in the first bottle, or raise it with distilled water, so as to form aqua ammoniæ of the prescribed density" (*Ed.*). The fluid measures in this formula are Imperial. We have by this process *Aqua Ammoniæ Fortior*, specific gravity 0.901 at 15°C. (59°F.), (U. S. P.), and *Aqua Ammoniæ*, specific gravity 0.960 at 15°C. (59°F.), (U. S. P.). A commercial form of ammonia water designated "F. F. F." or "20°" contains usually about 14 per cent of ammonia gas.

Description and Tests.—"A colorless, transparent liquid, having a very pungent odor, an acrid, alkaline taste, and a strongly alkaline reaction. Specific gravity 0.960 at 15°C. (59°F.). It is completely volatilized by the heat of a water-bath. On bringing a glass rod dipped into hydrochloric acid near the liquid, dense, white fumes are evolved. On slightly supersaturating 10 Cc. of ammonia water with diluted sulphuric acid, no empyreumatic odor or red color should be developed, and if to this liquid 1 Cc. of centinormal potassium permanganate V.S. be added, the pink color should not be completely destroyed within ten minutes (absence of readily oxidizable matters). If ammonia water be mixed with 4 times its volume of calcium hydrate T.S., it should not afford an immediate turbidity (only minute traces of carbonic acid); and if it be diluted with twice its volume of water, it should not be affected by ammonium oxalate T.S. (absence of calcium), nor should it be affected by hydrogen sulphide T.S., either before or after neutralization with hydrochloric acid (absence of metallic impurities). If ammonia water be slightly supersaturated with nitric acid, it should not be affected by barium chloride T.S. (absence of sulphates), nor by silver nitrate T.S. (chlorides); and if a third portion of the acidulated liquid be evaporated on a water-bath to dryness, it should afford a colorless residue, which, on ignition, should be completely volatilized (absence of coal-tar bases, and of fixed impurities). To neutralize 3.4 Gm. (3.54 Cc.) of ammonia water should require 20 Cc. of normal sulphuric acid (each cubic centimeter corresponding to 0.5 per cent of ammonia), rosolic acid being used as indicator"—(U. S. P.).

Occasionally a commercial form of ammonia water is prepared by adding to the ammoniacal liquor derived from gas works a quantity of milk of lime and passing the gas so obtained into water. If prepared in this manner, however, the product is apt to contain certain empyreumatic substances rendering it difficult of purification. Purification of such a product is accomplished, however, by passing the ammoniacal gas through a series of wash-bottles and lastly through charcoal contained in a series of tubes.

A delicate test for ammonia in aqueous solution is that with Nessler's reagent. The specific gravity of solution of ammonia will show the percentage of ammonia contained in the solution. Davy, in "*Elements of Chemical Philosophy*," p. 268, has given the following table for this purpose.

100 parts of specific gravity at 15° C. (59° F.) contain of ammonia:

SP. GR.	AMMONIA.	SP. GR.	AMMONIA.
0.8750.....	32.50	0.9435.....	14.53
0.8875.....	29.25	0.9476.....	13.46
0.9000.....	26.00	0.9513.....	12.40
0.9054.....	25.37	0.9545.....	11.56
0.9166.....	22.07	0.9573.....	10.82
0.9255.....	19.54	0.9597.....	10.17
0.9326.....	17.52	0.9619.....	9.60
0.9385.....	15.88	0.9692.....	9.50

Action and Toxicology.—Water of ammonia is a powerful irritant and narcotic poison, producing, in large doses, tetanus and coma, and in smaller quantity, inflammation or ulceration. Plants exposed to its vapors, shrivel and fade; animals are asphyxiated by it. Stronger ammonia applied to the cutaneous surface occasions heat and burning pain, with redness and vesication. If in large amount and long applied, a painful and even gangrenous ulcer, difficult to heal, is produced. The vapors inhaled, produce sneezing, burning of the nasal membranes and increased lachrymation, and in contact with the eye occasion burning pain and conjunctival inflammation. The inhalation of the gas, if strong and in sufficient quantity, may produce inflammation of the mouth and broncho-pulmonary tract, and occasionally causes cedema of the glottis, and death. If the person be insensible, the inhalation may cause death by asphyxiation. Internally, small doses do not sensibly affect the healthy individual, but are prompt in showing their effects in low states of the nervous system. Tension in the head, exhalation, increase of strength, with greater activity of the cutaneous, renal, and bronchial functions, are observed. Such effects are not followed by depression. Large doses cauterize the parts over which it passes, and visceral inflammation, with local cedema, follows. Death may be produced by moderate amounts, while again excessive quantities have been followed by recovery. The antidotes to it when swallowed in large doses, or in an undiluted state, are acids, as vinegar, juice of oranges, lemons, cider, etc., which should be administered at once to secure any good effects; they combine with the ammonia, forming harmless salts; or olive oil may be given. Inflammatory symptoms must be met according to indications. In poisoning by inhalation, the best antidote is the vapor of hydrochloric acid cautiously inhaled.

Medical Uses and Dosage.—In medicinal doses, ammonia water is an energetic stimulant, especially of the nervous system, prompt, diffusible, and transient. It is adapted for speedily rousing the action of the vascular and respiratory systems, and for the prompt alleviation of *spasm*. It exerts but little action on the cerebral functions, while it stimulates the vascular system. It acts as a useful antacid in cases of *acid stomach*, and in diseases which are caused or augmented in severity by this gastric condition, as *sick headache*, *spasm*, *heart-burn*, *palpitation*, etc. It has likewise been used as a stimulant and antispasmodic in *neuralgia* of the face and head, *asthma*, *pertussis*, and *delirium tremens*; it is highly recommended as an internal stimulant in cases of *retrocession of old and obstinate cutaneous eruptions*. The vapor of water of ammonia, inhaled through the nostrils, makes a powerful impression on the nervous system, and is useful in *syncope*, *asphyxia*, and to prevent an attack of *epilepsy*, *hysteria*, etc. Ammonia water should be remembered as the antidote to *poisoning* by the inhalation of the vapors of chlorine and bromine. By intravenous injection, ammonia water has promptly antidoted the toxic effects of hydrocyanic acid, hydrochloric acid, privy gas, and alcoholic intoxication. I have used the water of ammonia successfully in the treatment of *hydrophobia*, an account of which will be found in the *Western Medical Reformer*, Vol. VI, Oct., 1846, p. 83; since which it has been used by others in this country and Europe, and with very successful results, and some have also found it a very efficient remedy against the *bites of venomous serpents* (J. King). On the other hand, several observers, Fayer among them, uphold the views of Fontana, of Florence, enunciated in 1782, to the effect that it is useless, or at least very uncertain in its action, in such accidents. It is very probable, however, that in some cases it tends to sustain the heart, and should be cautiously used by intravenous injection. As an inhalation to check *incipient*

catarrhal disorders of the respiratory passages, it has not found much favor in our school. It is an appropriate remedy in retrocession of the eruption in the *exanthemata*, and to sustain the vital powers in the torpor, prostration, or sinking of *typhoid* and *typhus fevers*, and other adynamic conditions. It is also of value in the cold stage of *congestive intermittents*. Externally, water of ammonia may be used as a rubefacient, irritant, or vesicant, as may be required, in *rheumatic* and *neuralgic pains*, and internal inflammations. It has been found to benefit *burns* and *chilblains* when superficial and not too extensive. The *stings* of bees and wasps, and the *bites* of mosquitoes, spiders, and like insects, are relieved by its local application, and it should be given internally when depressing effects follow such accidents. Its combination with oil forms a rubefacient liniment much used. Dose of water of ammonia, from 5 to 20 or 30 drops, sufficiently diluted. (See also *Aqua Ammoniae Fortior*).

Specific Indications and Uses.—Feeble circulation, with pallor and lack of expression in the lips, eyes dull, with pupils dilated or immobile; nose, ears, and forehead cold—want of stimulus; stings and bites of insects and reptiles.

AQUA AMMONIÆ FORTIOR (U. S. P.)—STRONGER AMMONIA WATER.

Preparation.—(See *Aqua Ammoniae*).

Description.—“An aqueous solution of ammonia ($\text{NH}_3=17.01$) containing 28 per cent, by weight, of the gas. Stronger ammonia water should be kept in strong, glass-stoppered bottles, not completely filled, in a cool place. A colorless, transparent liquid, having an excessively pungent odor, a very acrid and alkaline taste, and a strongly alkaline reaction. Specific gravity 0.901 at 15°C . (59°F). If stronger ammonia water be diluted with twice its volume of water, it should respond to the reactions and tests described under ammonia water (see *Aqua Ammoniae*). To neutralize 1.7 Gm. (1.88 Cc.) of stronger ammonia water should require 28 Cc. of normal sulphuric acid (each cubic centimeter corresponding to 1 per cent of ammonia), rosolic acid being used as indicator”—(U. S. P.).

Action and Medical Uses.—Undiluted, this stronger water of ammonia is entirely too potent for medicinal use. Its principal employment is externally as a counter-irritant. The formula for *Gondret's Ammoniacal Ointment* as improved is as follows: Take of lard, 16 drachms, oil of sweet almonds, 1 drachm; melt the lard and mix it with the oil in a wide-mouthed vial with a glass stopper; then add aqua ammoniæ fortior, specific gravity 0.901, $8\frac{1}{2}$ drachms; close the bottle, mix the contents by agitation, and keep in a cool place. Rubbed on the skin it causes rubefaction, but if covered by a compress it speedily produces vesication. If well prepared, vesication will take place in from 8 to 12 minutes. In cases of poisoning from swallowing this stronger water of ammonia, the means to be used are the same as named above for the weaker solution (see also *Aqua Ammoniae*).

AQUA AMYGDALÆ AMARÆ (U. S. P.)—BITTER ALMOND WATER.

Preparation.—“Oil of bitter almond, one cubic centimeter (1 Cc.) [16 M]; distilled water, nine hundred and ninety-nine cubic centimeters (999 Cc.) [33 fl̄, 374 M], to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Dissolve the oil in the distilled water by agitation, and filter through a well-wetted filter”—(U. S. P.).

This medicated water soon undergoes decomposition, on which account it should only be prepared as required, and never in large quantities. It is a sedative, of the character of hydrocyanic acid, and is preferable to the distilled water of bitter almonds; which is more dangerous in its effects upon the system, and which is sold under the same name; great care is required to distinguish between these two preparations in dispensing prescriptions.

Action, Medical Uses, and Dosage.—Bitter almond water may be used in all cases where hydrocyanic acid or its sedative compounds are useful, as in

whooping-cough, pulmonary affections, etc. It is more commonly used as an addition to other medicines to impart its peculiar flavor to them. The dose of bitter almond water, when freshly made, is from 1 to 2 fluid drachms, which may be repeated 2 or 3 times daily. Care should be had not to confound this preparation with some of the European preparations which are much stronger. Even this is uncertain in strength, and not very safe as a remedy.

AQUA ANETHI.—DILL WATER.

Preparation.—"Dill fruit, bruised, 1 pound; water, 2 gallons. Distill 1 gallon"—(*Br. Ph.*). Imperial measure.

History, Action, Medical Uses, and Dosage.—This water is but little used in America. It is slightly opalescent when first made, and resembles anise water in odor and taste. It may be administered in *infantile colic*. When administered to a nursing mother it is said to impart its flavor to the milk. The dose is from 1 fluid drachm to 1 fluid ounce.

AQUA ANISI (U. S. P.)—ANISE WATER.

Preparation.—"Oil of anise, two cubic centimeters (2 Cc.) [32 M]; precipitated calcium phosphate, four grammes (4 Gm.) [62 grains]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 391 M]. Triturate the oil of anise with the precipitated calcium phosphate, add the water gradually, under constant trituration, and filter"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Used principally as a pleasant vehicle for the administration of magnesia, and such cathartics as jalap, rhubarb, and senna, to modify their griping action. It is useful also as a carminative to expel flatus in *flatulent colic*, and *indigestion* accompanied with gaseous accumulations. The dose is from 2 fluid drachms to 1 fluid ounce.

AQUA AURANTII FLORUM (U. S. P.)—ORANGE FLOWER WATER.

Preparation.—"Stronger orange flower water, distilled water, of each, 1 volume. Mix them immediately before use"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This water is employed chiefly as a delicately perfumed vehicle for other substances. As a medicine, it has little to recommend it, though it has been administered in *cardiac palpitations*, and *head-aches* of a neuralgic character in nervous females. It has likewise been employed in various *hysteroidal affections*.

AQUA AURANTII FLORUM FORTIOR (U. S. P.)—STRONGER ORANGE FLOWER WATER.

SYNONYMS: *Aqua aurantii florum* (*Pharm.* 1880), *Triple orange flower water*.

Source, History, and Tests.—"Water saturated with the volatile oil of fresh orange flowers, obtained as a by-product in the distillation of the oil of orange flowers. It should be kept in loosely-stoppered bottles, in a dark place. Stronger orange flower water should be neutral to litmus paper, and possess a strong odor of fresh orange flowers. It should be colorless and clear, or only faintly opalescent, not mucilaginous, and give no reaction with hydrogen sulphide T.S. or ammonium sulphide T.S. (absence of metallic impurities)"—(*U. S. P.*).

Eau de fleurs d'Orange, of the French, was prepared by taking orange flowers, 10 parts, and water, 30 parts, and distilling therefrom 20 parts. If in this manner 2 pounds of orange flower water are obtained from each pound of flowers employed, the product is called *double orange flower water*; if pound for pound is obtained, it is *quadruple orange flower water*; if 3 pounds are obtained from 2 pounds of flowers, it is *triple orange flower water*; if the double be cut with an equal amount of water it produces *simple orange flower water* (Jourdan, *Pharmacopée Universelle*, 1840).

Description and Uses.—Orange flower water (distilled) is a clear, colorless, and agreeably aromatic liquid, having an odor and taste distinct from that prepared from oil of neroli (oil of orange flowers). It may be faintly opalescent. A mucilaginous material sometimes separates from the commercial water, which may be removed by filtration, after being previously agitated with pulverized kaolin. Should it become acid in reaction, distilling from magnesia will restore it to its normal condition. It is used in preparing *Aqua Aurantii Florum*.

AQUA CAMPHORÆ (U. S. P.)—CAMPHOR WATER.

Preparation.—"Camphor, eight grammes (8 Gm.) [123 gr.]; alcohol, five cubic centimeters (5 Cc.) [81 M]; precipitated calcium phosphate, five grammes (5 Gm.) [77 gr.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Triturate the camphor with the alcohol and precipitated calcium phosphate, then with the water gradually added, and filter"—(U. S. P.).

The first trituration with alcohol, by destroying the tenacity with which the particles of camphor adhere together, renders it more readily pulverizable; the second trituration with the calcium salt subdivides it still more finely, so that the water can more readily act upon it, and produce the desired medicated water. The filtration removes the calcium phosphate and excess of camphor from the solution. Ice-cold water will dissolve more camphor than water at the ordinary temperature.

Action, Medical Uses, and Dosage.—Camphor water is a very feeble preparation of camphor, and is principally used as a vehicle for the administration of some other remedies. It has, however, been useful in the *typhoid stage of febrile diseases* to produce sleep and quietness, also to relieve severe *after-pains, colic, mild neuralgic pains, dysmenorrhœa* in nervous individuals, *singultus, nervous debility*, and in all cases where small doses of camphor are indicated. Its dose varies from $\frac{1}{2}$ fluid ounce to 2 fluid ounces, every 1, 2, or 3 hours, as circumstances require. Externally, it has been found useful in *chronic ophthalmia*, in combination with rose water, infusion of golden seal, etc.

AQUA CARUL.—CARAWAY WATER.

Preparation.—Prepare caraway water in the same manner as cinnamon water on page 247, using oil of caraway instead of oil of cinnamon.

Action, Medical Uses, and Dosage.—The properties, uses, and dose of caraway water are the same as for anise water. It has a strong odor of caraway.

AQUA CHLORI (U. S. P.)—CHLORINE WATER.

"An aqueous solution of chlorine ($\text{Cl}=35.37$), containing at least 0.4 per cent of the gas"—(U. S. P.).

Preparation.—"Manganese dioxide, ten grammes (10 Gm.) [154 grs.]; hydrochloric acid, thirty-five cubic centimeters (35 Cc.) [1 fl. 3, 98 M]; water, seventy-five cubic centimeters (75 Cc.) [2 fl. 3, 257 M]; distilled water, four hundred cubic centimeters (400 Cc.) [13 fl. 3, 252 M]. Place the dioxide in a flask connected by a suitable tube with a small wash bottle containing fifty cubic centimeters (50 Cc.) [1 fl. 3, 331 M] of water, and connect this with a bottle having a capacity of one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M], and containing four hundred cubic centimeters (400 Cc.) [13 fl. 3, 252 M] of distilled water which has previously been boiled and allowed to cool. Add to the dioxide in the generating flask the hydrochloric acid, previously diluted with twenty-five cubic centimeters (25 Cc.) [409 M] of water, and, by means of a sand-bath, apply a gentle heat. Conduct the generated chlorine through the water contained in the wash-bottle into the bottle containing the distilled water, which should be loosely stopped with cotton and kept, during the operation, at a temperature of about 10°C . (50°F). When the air has been entirely displaced by the gas,

disconnect the bottle from the apparatus, and, having inserted the stopper, shake the bottle, loosening the stopper from time to time, until the gas ceases to be absorbed. If necessary, reconnect the bottle with the apparatus, and continue passing the gas, and agitating, until the distilled water is saturated. Finally, pour the chlorine water into small, dark amber-colored, glass-stoppered bottles, which should be completely filled therewith, and keep them in a dark and cool place. Chlorine water, even when kept from light and air, is apt to deteriorate. When it is required of full strength, it should be freshly prepared"—(U. S. P.).

In the preparation of chlorine and chlorine water, the operator should be cautious not to inhale the gas, as it is a very poisonous irritant to the respiratory mucous surface. In case such an accident should occur, ammonia water, or carbon disulphide, should be cautiously inhaled. Care should also be taken not to inhale sufficient of these compounds to produce poisonous effects.

Description.—"A clear, greenish-yellow liquid, having the suffocating odor and disagreeable taste of chlorine, and leaving no residue on evaporation. It instantly decolorizes dilute solutions of litmus, indigo, and other vegetable coloring matters. When shaken with an excess of mercury until the odor of chlorine has disappeared, the remaining liquid should be at most but faintly acid (limit of hydrochloric acid). On adding 17.7 Gm. of chlorine water to a solution of 1 Gm. of potassium iodide in 10 Cc. of water, the resulting deep-red liquid should require, for complete decoloration, not less than 20 Cc. of decinormal sodium hyposulphite V.S. (corresponding to at least 0.4 per cent of chlorine)"—(U. S. P.).

Chlorine water, formerly called *oxymuriatic acid*, has an astringent, nauseous taste, and possesses all the bleaching and oxidizing properties of the gas. It has no acid reaction, unless it has been exposed to light. With water near its freezing point, it combines and forms a crystalline hydrate of a pale, yellowish-green color, which Faraday found to contain 27.7 per cent of chlorine. This practically corresponds to the formula $\text{Cl}_2 + 10\text{H}_2\text{O}$.

Action, Medical Uses, and Dosage.—Chlorine water is a powerful antiseptic, destroying foul and noxious effluvia, and also acts upon the system as a stimulant. It has been used internally in *chronic hepatitis*, *typhus*, *cynanche maligna*, and *scarlet fever*, in doses of 1 or 2 fluid drachms largely diluted with water, and repeated 2 or 3 times a day. Diluted with water, it has been employed as a gargle in the throat affections attending the *exanthemata*, in *putrid affections* of the mouth and throat; as a wash or local application in *indolent*, *gangrenous*, and *carcinomatous ulcerations*, in *indolent abscesses*, *boles*, and *fistulous ulcers*. In *hepatic diseases* its internal should be associated with its external use, bathing around and over the region of the liver. Chlorine gas inhaled in small quantity has been found serviceable in *chronic catarrh*, *chronic bronchitis*, and even in *phthisis*. At first, expectoration is augmented, but eventually it decreases with marked improvement in the general health. Ten or twenty drops of chlorine water may be placed in 2 or 3 fluid drachms of water in a glass inhaler, to which add 1 or 2 minims of sulphuric acid. Upon placing this in a water-bath at 37.7°C . (100°F .), the chlorine gas will be driven off, and may be inhaled by the patient for several minutes, repeating the operation several times a day (C.—Elliottson). A solution of from 5 to 10 minims, applied by atomization, would be preferable to the latter methods. However, it is now seldom employed in pulmonary complaints. Its best use is in *fetid* local troubles requiring a deodorizer and powerful disinfectant. Dose from 1 to 4 fluid drachms largely diluted. In large doses it is an irritant poison. The treatment after emesis consists in administering albumen, milk, veal and other animal broths, a thin mixture of lime-water, or flour and water, etc.

Chlorine ($\text{Cl}=35.37$).—Chlorine occurs in nature only in combination, principally in common salt (sodium chloride), of which it constitutes about 60 per cent. It is therefore a prominent constituent of sea-water. It was discovered in 1774 by Scheele, who named it "*dephlogisticated muriatic acid*" and "*oxymuriatic acid*." Chlorine was proved to be an element by H. Davy in 1810. Chlorine gas may be prepared in several ways beside that indicated under *Aqua Chlorig*. It is usually obtained by the interaction of diluted sulphuric acid, sodium chloride, and manganese dioxide, according to the following equation: $2\text{NaCl} + 3\text{H}_2\text{SO}_4 + \text{MnO}_2 = \text{MnSO}_4 + 2\text{NaHSO}_4 + 2\text{H}_2\text{O} + \text{Cl}_2$. Chlorine gas is prepared on a large scale in the manufacture of bleaching powder by various processes (see *Calx Chlorata*). Chlorine gas is of a greenish-yellow color, with a pungent and suffocating odor, a peculiar and somewhat astring-

ent taste, and is highly irritating when respired, exciting cough and great irritation of the lungs, even when considerably diluted with common air. In more concentrated state it may produce hemoptysis, with intense pain, and even death may result. It has the specific gravity 2.48. Under a pressure of 6 atmospheres at 0° C. (32° F.), or subjected to a temperature of -34° C. (-42.8° F.), at ordinary pressure, chlorine gas is condensed into a bright-yellow liquid of specific gravity 1.33. Water at 15.5° C. (60° F.) dissolves twice its volume of the gas. It unites with many metals under combustion to form *chlorides*; also with organic compounds. On account of its great affinity for hydrogen, it acts as a powerful bleaching agent in the presence of moisture. It is a powerful, diffusible disinfectant.

AQUA CHLOROFORMI (U. S. P.)—CHLOROFORM WATER.

Preparation.—"Chloroform, distilled water, each a sufficient quantity. Add enough chloroform to a convenient quantity of distilled water contained in a dark amber-colored bottle, to maintain a slight excess of the former, after the contents have been repeatedly and thoroughly agitated. When chloroform water is required for use, pour off the needed quantity of the solution, refill the bottle with distilled water and saturate it by thorough agitation, taking care that there be always an excess of chloroform present"—(U. S. P.).

Action, Medical Uses, and Dosage.—Chloroform water is an agreeable vehicle for the administration of other medicines, and is particularly useful in *non-inflammatory diarrhœa, flatulent colic, gastralgia*, and other forms of *abdominal pain*. It is a stimulant to mucous surfaces, and is useful as a gargle and mouth wash. On account of its preservative qualities, it is valuable in solutions containing organic materials, which, without some antifermentative, would undergo decomposition. Medicinal mixtures to be used in a few days may be preserved by it in summer time. It forms a pleasant vehicle for cough mixtures, and it alone is useful in *coughs* characterized by tickling, irritation, or other nervous sensations in the bronchiæ and throat. *Whooping-cough* is palliated by it. It is likewise employed as a local hemostatic, where bleeding is small in amount. Dose, from 1 fluid drachm to 1 fluid ounce.

AQUA CINNAMOMI (U. S. P.)—CINNAMON WATER.

Preparation.—"Oil of cinnamon, two cubic centimeters (2 Cc.) [32 M]; precipitated calcium phosphate, four grammes (4 Gm.) [62 grs.]; distilled water a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. Triturate the oil of cinnamon with the precipitated calcium phosphate, add the distilled water gradually, under continued trituration, and filter"—(U. S. P.).

When cinnamon water is prepared with true oil of cinnamon, it soon becomes turbid from oxidation of the oil, and the formation of *cinnamic acid* ($C_6H_5.CH:CH.COOH$), which crystallizes from the water. Oil of Chinese cinnamon yields a water remaining clear for a much longer time.

Action, Medical Uses, and Dosage.—Cinnamon water is useful in *passive hemorrhage* from the *lungs, stomach, kidneys*, or *uterus*, in *chronic diarrhœa* and *dysentery*, and in *flatulency*. It is frequently employed to cover the unpleasant taste of other remedies, especially opiates, and will often allay vomiting. Its dose is from 2 fluid drachms to 2 fluid ounces. It should not be used when fever or inflammation is present.

AQUA CREOSOTI (U. S. P.)—CREOSOTE WATER.

Preparation.—"Creosote, ten cubic centimeters (10 Cc.) [162 M]; distilled water, nine hundred and ninety cubic centimeters (990 Cc.) [30 fl̄3, 229 M], to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. Agitate the creosote vigorously with the distilled water, and filter through a well-wetted filter"—(U. S. P.).

Action, Medical Uses, and Dosage.—Creosote water may be employed as a lotion where the discharges are fetid, ichorous, and profuse, as in *ulcers, burns*,

and *gangrene*. It may also be used advantageously in catarrhal states, as *leucorrhæa* and *gleet*, and in some forms of skin diseases, especially *syccosis* and *prurigo*. Internally, it may be given in *obstinate singultus*, *diabetes*, and *chronic pulmonary complaints* with profuse and offensive secretions. The dose is from 1 to 4 fluid drachms.

AQUA DESTILLATA (U. S. P.)—DISTILLED WATER.

FORMULA: H_2O . MOLECULAR WEIGHT: 17.96.

Preparation.—"Water, one thousand volumes (1000 vol.), to make eight hundred volumes (800 vol.). Distill the water from a suitable apparatus provided with a block-tin or glass condenser. Collect the first one hundred volumes (100 vol.), and throw this portion away. Then collect eight hundred volumes (800 vol.) and keep the distilled water in glass-stoppered bottles, rinsed with hot distilled water immediately before being filled"—(U. S. P.).

Description and Tests.—"A colorless, limpid liquid, without odor or taste, and perfectly neutral to litmus paper. The transparency of distilled water should not be affected, nor should any color be imparted to it, by test solutions of hydrogen sulphide or ammonium sulphide (absence of metallic impurities), or by those of barium chloride (sulphates), silver nitrate (chlorides), ammonium oxalate (calcium), or mercuric chloride (ammonia); nor should its transparency be affected when mixed with twice its volume of calcium hydrate T.S. (absence of carbonic acid). It should give no reaction for nitrates or nitrites when tested as described under Water (see *Aqua*). When 1000 Cc. of distilled water are evaporated on a water-bath to dryness, no residue should remain. On heating 100 Cc. of distilled water acidulated with 10 Cc. of diluted sulphuric acid, to boiling, and subsequently adding 1 Cc. of centi-normal potassium permanganate V.S., the color of the liquid should not be completely destroyed by boiling for 10 minutes, nor by afterwards setting the vessel aside, well covered, for 10 hours (absence of organic or other oxidizable matters)"—(U. S. P.).

The demand of the U. S. P. that 1000 Cc. of distilled water, evaporated on a water-bath to dryness, should leave no residue, is probably impossible to strictly comply with. The amount of residue which good distilled water may leave upon evaporation, should not exceed 1 part in 100,000 (*Am. Jour. Pharm.*, 1896, p. 187). Distilled water is apt to become contaminated with fresh water algae (*confervæ*).

In many pharmaceutical and chemical processes, distilled water is very essential, while in others, pure spring or river, or rain water, will be sufficient. The reason for throwing away the first 100 parts which are distilled over, is that any volatile principles which may be present, as ammonia, carbonic acid gas, etc., and which may pass over with the first portions, may be removed. The last 100 parts, left in the still, contain the residual impurities, and if allowed to pass over might give to the product an empyreumatic odor and taste. Carbon dioxide will be absorbed by distilled water if the latter be exposed to the atmosphere for any considerable time. In this case lime-water will occasion turbidity in the distilled water. Distilled water is nearly always employed in making the medicated waters, in diluting acids, and in making solutions of various salts, as the alkaloidal salts, silver nitrate, permanganate of potassium, etc. For other uses, see *Aqua*.

AQUA FENICULI (U. S. P.)—FENNEL WATER.

Preparation.—"Oil of fennel, two cubic centimeters (2 Cc.) [32 M]; precipitated calcium phosphate, four grammes (4 Gm.) [62 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Triturate the oil of fennel with the precipitated calcium phosphate, add the distilled water gradually, under continued trituration, and filter"—(U. S. P.).

Action, Medical Uses, and Dosage.—Fennel water is a pleasant aromatic stimulant and carminative; and may be added to other medicines to render them more agreeable. It may be employed for *gastric acidity* and *flatulent colic*. The dose is from 1 fluid drachm to 1 fluid ounce.

AQUA HAMAMELIDIS.—HAMAMELIS WATER.

SYNONYMS: *Distilled hamamelis, Distillate of hamamelis, Distilled witch-hazel, Witch-hazel extract.*

Preparation.—Take of the green leaves and young twigs of witch-hazel, any convenient amount. Place them in a copper still and cover them with a mixture of alcohol, 1 part, water, 9 parts. Boil by direct fire and recover 2 parts of distillate for each part of leaves employed. For commercial purposes very inferior preparations are made in which the alcohol is decreased, and the distillate increased.

Uses.—(See *Hamamelis*).

AQUA HAMAMELIDIS SPIRITUOSA (N. F.).—*Hamamelis water, Witch-hazel water, Witch-hazel extract.* *Formulary number, 10.* "Hamamelis, shoots and twigs, ten thousand grammes (10,000 Gm.) [22 lbs. av., 323 grs.]; water, twenty thousand cubic centimeters (20,000 Cc.) [5 Cong., 3 fl. 3, 30 M.]; alcohol, fifteen hundred cubic centimeters (1500 Cc.) [50 fl. 3, 345 M.]. Place the hamamelis in a still, add the water and alcohol, and allow the mixture to macerate during 24 hours. Distill ten thousand cubic centimeters (10,000 Cc.) [2 Cong., 8 fl. 3, 102 M.], by applying direct heat, or preferably, by means of steam."

Note.—"This preparation should be made only from the fresh young twigs of hamamelis, which are collected for this purpose, preferably when the plant is in flower, in the late autumn of the year"—(*Nat. Form.*).

AQUA HEDEOMÆ.—PENNYROYAL WATER.

Preparation.—Triturate oil of American pennyroyal, $\frac{1}{2}$ fluid drachm, with precipitated calcium phosphate, 1 drachm, then with distilled water, 2 pints, to be gradually added; finally, filter through paper.

Action, Medical Uses, and Dosage.—Pennyroyal water may be used as a substitute for, and in the same doses as peppermint and spearmint waters. Some persons prefer it.

AQUA HYDROGENII DIOXIDI (U. S. P.).—SOLUTION OF HYDROGEN DIOXIDE.

"A slightly acid, aqueous solution of hydrogen dioxide ($H_2O_2=33.92$), containing, when freshly prepared, about 3 per cent, by weight, of the pure dioxide, corresponding to about 10 volumes of available oxygen"—(*U. S. P.*).

SYNONYM: *Solution of hydrogen peroxide.*

History and Preparation.—Dioxide of hydrogen was discovered in 1818, by M. Thénard, and named *oxygenated water*. It is produced when peroxide of potassium, sodium, barium, strontium, or calcium, is digested with any acid that forms a salt with the base. Thénard prepared it by acting upon barium dioxide (peroxide of barium) with diluted hydrochloric acid, thus: $BaO_2 + 2HCl = H_2O_2 + BaCl_2$; and afterward separating the barium chloride by the cautious addition of sulphate of silver. Clermont reported finding it in the juices of a great variety of plants, but the experiments of Belluci failed to support him. Struve states that the combustion of hydrogen in the atmosphere produces hydrogen dioxide, together with ozone and ammonium nitrite. Struve and others report that it is often present in the atmosphere, in rain-water, and in snow; Houzeau failed in his first attempt to find it in rain-water, but afterward discovered it in snow, at Rouen (*Compt. Rend.* lxx, 519). At the present time hydrogen dioxide is made by decomposing hydrated barium dioxide with sulphuric acid, as follows: Freshly prepared hydrated dioxide of barium is gradually added to a cold mixture of sulphuric acid and water (not less than 5 of water to 1 of acid) until the mixture becomes very slightly acid; the sulphate of barium is then separated by filtration; the excess of sulphuric acid in the filtrate is now removed, by the cautious addition of dilute baryta solution; again filtered; and the aqueous solution of hydrogen dioxide concentrated in vacuo over sulphuric acid: $BaO_2 \cdot 8H_2O + H_2SO_4 = BaSO_4 + H_2O_2 + 8H_2O$. When the solution becomes more concentrated, an addition of a small amount of sulphuric acid will give it more stability (Thénard).

The official solution of hydrogen dioxide is prepared as follows: "Barium

dioxide, three hundred grammes (300 Gm.) [10 oz. av., 255 grs.]; phosphoric acid, diluted sulphuric acid, distilled water, of each, a sufficient quantity. Pour five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 m.] of cold distilled water into a suitable bottle, add to it the barium dioxide in such a way that it shall not form lumps, and shake vigorously so that a uniform mixture may result. Provide suitable means of refrigeration, so that the bottle and contents may be kept at a temperature below 10° C. (50° F.), and shake it thoroughly every few minutes during half an hour. Afterwards, continuing the refrigeration, shake it occasionally, but vigorously, until the dioxide has become fully hydrated, which may be recognized from the fact that only a small portion of the water separates from it on standing, and that it may be mixed with the separated water without great effort by shaking. Having introduced ninety-six cubic centimeters (96 Cc.) [3 fl. 3, 118 m.] of phosphoric acid into a bottle having the capacity of about two thousand cubic centimeters (2000 Cc.) [67 fl. 3, 302 m.], add to it three hundred and twenty cubic centimeters (320 Cc.) [10 fl. 3, 394 m.] of distilled water, cool the mixture, and remove fifty cubic centimeters (50 Cc.) [1 fl. 3, 332 m.], as a reserved portion. Now add the well-mixed magma, in about four portions, to the acid liquid, and mix them intimately by vigorous and continuous shaking, cooling the bottle after each addition of magma. From time to time test the reaction of the liquid, and, when it becomes alkaline, add to it, cautiously, a little of the reserved phosphoric acid, until the liquid has again acquired an acid character. Repeat the agitation from time to time, and also the cautious addition of phosphoric acid, as long the liquid becomes alkaline on prolonged, vigorous shaking. If necessary, a further quantity of phosphoric acid should be diluted with distilled water, in the proportion above given, and a portion of this liquid used for saturation. Having finally shaken the bottle again very thoroughly, and until the liquid part is neutral to litmus paper, set it aside until the precipitate occupies only about one-third of the volume of the contents, and pour the supernatant liquid upon a wetted, double, rapidly-acting, white filter, of a diameter of 30 centimeters (11.8 inches). Then transfer the semi-liquid precipitate to the filter, rinse the bottle with one hundred cubic centimeters (100 Cc.) [3 fl. 3, 181 m.] of distilled water, transfer this to the filter, and when the liquid has drained off, wash the barium phosphate on the filter with distilled water, until the filtrate measures one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 m.]. Now add to it, first, 20 drops, and afterwards, if necessary, further, smaller quantities of diluted sulphuric acid, until a small portion of the liquid, after filtration (which may be assisted by a little starch), is no longer rendered cloudy by diluted sulphuric acid. Mix the cloudy liquid with about ten grammes (10 Gm.) [154 grs.] of starch by agitation, so that the starch may be thoroughly distributed, throughout the liquid, and then filter it through a well-wetted, white filter, of a diameter of 25 centimeters (9.8 inches), returning the first portions until it runs through clear. When all the liquid has passed, ascertain the percentage of hydrogen dioxide contained in it by the method of assay given below, and dilute the remaining liquid if necessary, so that it will contain 8 per cent of absolute hydrogen dioxide. Keep the product in loosely-stoppered bottles, in a cool place. Since solution of hydrogen dioxide will gradually diminish in strength, even when carefully kept, it should either be freshly made when wanted, or be kept on hand only in such quantity as will probably be consumed within a short time. Any solution which has become weaker, need not, for this reason, be thrown away, but may be reserved for an occasion when a weaker or diluted solution is prescribed or demanded. Or, it may be employed, when making a fresh supply, as a diluent of the stronger solution"—(*U. S. P.*).

Description.—Concentrated hydrogen dioxide is a colorless, odorless, oily appearing liquid, of sp. gr. 1.452, and does not solidify at -30° C. (-22° F.) (Thénard); it evaporates in vacuo at ordinary temperatures, without decomposition, and does not redden, but bleaches, litmus and turmeric paper; it has an astringent, bitter taste; when applied to the skin it first bleaches, and subsequently develops a white blister, accompanied with violent itching, followed by painful irritation. It mixes in all proportions with cold water, and when a solution, containing eight times its volume of oxygen, is heated to 50° C. (122° F.), the oxygen begins to be evolved, ebullition increases, and upon ceasing, water

only remains. Concentrated hydrogen dioxide evolves oxygen slowly at 20° C. (68° F.), but if quickly heated to 100° C. (212° F.), the separation is violent, and sometimes explosive (R. and S.). It is also decomposed with almost explosive violence when in contact with finely-divided metals, as gold, silver, and platinum, the metals remaining unaltered. The oxides of these metals are decomposed by, and in turn decompose, hydrogen dioxide; the metals being reduced to a metallic state, and free oxygen liberated; thus we have a powerful oxidizing agent which acts as a reducer. In other instances, hydrogen dioxide transforms many basic oxides into higher oxides. With solution of ferrocyanide of potassium it forms ferricyanide of potassium; with solution of ferrous sulphate it forms ferric sulphate. Manganese sulphate in alkaline solution is oxidized to manganese dioxide by hydrogen peroxide, while in acid solution manganese dioxide is reduced by it to a manganous salt under evolution of oxygen. An aqueous solution of hydrogen dioxide is used to clean and bleach old engravings and oil paintings, and, according to Cameron, the popular colorless solution perniciously employed to change dark hair to yellow is this substance.

Official solution of hydrogen dioxide is described as "a colorless liquid, without odor, slightly acidulous to the taste, and producing a peculiar sensation and soapy froth in the mouth; liable to deteriorate by age, exposure to heat, or protracted agitation. Specific gravity about 1.006 to 1.012 at 15° C. (59° F.). When exposed to the air at the ordinary temperature, or when heated on a water-bath at a temperature not exceeding 60° C. (140° F.), the solution loses chiefly water. When rapidly heated, it is liable to decompose suddenly. Solution of hydrogen dioxide has an acid reaction, due to a small amount of free acid purposely allowed to remain in it for preservation"—(*U. S. P.*). Solution of hydrogen dioxide should be kept well corked and in a cool, dark place.

Tests.—When a solution of ferrous sulphate is mixed with phenol, the addition of a small amount of hydrogen dioxide, gives a green color; of a large amount, a dark-green precipitate. According to Parnell, the test will fail if the phenol be added after the admixture with hydrogen dioxide. Hydrogen dioxide liberates iodine from a solution of iodide of potassium and ferrous sulphate (Schönbein), a reaction so delicate as to form the blue iodide of starch, when but 1 part of hydrogen dioxide is present in 25,000,000 parts of solution. Another delicate reaction is that based on the formation of perchromic acid, as described under the *U. S. P.* tests which are as follows:

"On adding to 10 Cc. of water, in a test-tube, 1 drop of potassium chromate T.S., then 10 drops of diluted sulphuric acid, and pouring a few cubic centimeters of ether on top, the subsequent addition of a few drops of solution of hydrogen dioxide, even when considerably diluted, will cause a blue color to appear at the zone of contact of the two liquids. After shaking, the ethereal layer will separate with a blue color. Upon evaporating 50 Cc. of the solution to dryness, on a water-bath, not more than 0.25 Gm. of residue should remain. Upon evaporating 50 Cc. of the solution, previously rendered alkaline by sodium hydrate T.S., to dryness, transferring the dry residue to a watch-glass, moistening it with sulphuric acid, and setting the glass in a moderately warm place for a few hours, the surface of the glass, after being washed, should exhibit no sign of corrosion (absence of hydrofluoric acid). Fifty Cc. of the solution should not require more than 0.5 Cc. of potassium hydrate V.S. to render the liquid alkaline, phenolphthalein being used as indicator (limit of free acid). The addition of a few drops of diluted sulphuric acid to 10 Cc. of the solution should produce no turbidity or precipitate (absence of barium)"—(*U. S. P.*).

Valuation of Solution of Hydrogen Dioxide.—"Dilute 10 Cc. of the solution with water to make 100 Cc. Transfer 17 Cc. of this liquid (containing 1.7 Cc. of the solution) to a beaker, add 5 Cc. of diluted sulphuric acid, and then, from a burette, decinormal potassium permanganate V.S., until the liquid just retains a faint pink tint after being stirred. Each cubic centimeter of the decinormal potassium permanganate V.S. corresponds to 0.0017 Gm. of absolute hydrogen dioxide. To express the strength of any solution of hydrogen dioxide approximately in volumes of available oxygen (that is, in volumes of oxygen, given off by 1 volume of the solution upon decomposition), multiply the number of cubic centimeters of decinormal permanganate V.S. decolorized by 1 Cc. of

the solution, by 0.56 (0.5594); or those decolorized by 1.7 Cc. of the solution, by 0.33. (It is assumed that 1000 Cc. of oxygen, at 0° C. [32° F.] and 760 Mm. pressure, weigh 1.43 Gm.) To express the strength in percentage (by weight) of absolute hydrogen dioxide, multiply the number of cubic centimeters of decinormal permanganate V.S. decolorized by 1 Cc. of it, by 0.17; or divide the number of cubic centimeters of permanganate V.S. decolorized by 1.7 Cc. of it, by 10"—(U. S. P.).

Action, Medical Uses, and Dosage.—This agent was introduced to the profession as a therapeutical means, by Dr. B. W. Richardson, of London, England (1860). From experiments instituted by him, he found that certain animal substances when brought into contact with a solution of peroxide of hydrogen, liberated its oxygen, as was the case with fibrin, carbonic acid, etc. The presence of free oxygen in the system must act as a stimulant, oxygenate the blood, and antagonize *septic conditions*; he, therefore, recommended its employment, therapeutically, in all cases marked by deficient oxidation; as an antidote to various *poisons*; in *low fevers*, and in all cases manifesting deficient oxidation; in *diabetes*, *tetanus*, and *cancer*. Subsequently, from a larger experience, he advised it as useful in *chronic rheumatism*, in *scrofulous tumors* and *abscesses*, in *pertussis* to mitigate the paroxysms, in the *dyspnœa* attending *chronic bronchitis*, and in *poisoning by narcotics*. He recommended that the solution employed should be charged with 10 volumes of oxygen, which could be readily determined by an estimate of the amount of oxygen present in the peroxide of barium employed in its manufacture; and of this preparation the dose varies from 1 to 4 fluid drachms, largely diluted with water, to be repeated 3 or 4 times daily. Richardson later stated that nothing except a change of air acted as quickly in checking *whooping-cough*. Both the aqueous solution and the ethereal solution (*ozonic ether*) have been employed internally, and the various experimenters with this agent, since its introduction, differ greatly in their views as to any therapeutical efficacy it may possess. It is altogether probable that the agent is destroyed in the stomach, so that but little of it as peroxide can enter into the system. As a remedy for *diabetes*, a disease in which it was once thought to be of particular value, it has entirely fallen into discredit. It is occasionally used as a test for blood stains.

It is its importance as a topical disinfectant and pus destroyer that gives peroxide of hydrogen its value in therapy at the present time. It is undoubtedly one of the best antiputrefactive agents in use. It is of value, however, only when putrefaction has already set in, and is of little or no value as a preventative of such changes, owing to its liability to decomposition. When brought into contact with the mucous tissues or ulcerations, it immediately coagulates the albuminous material and leaves a whitish coating on the parts, doing no injury, however, to the tissues. At the same time gas is copiously evolved as shown by the frothing which ensues, and particularly if pus be present. It stands unrivalled as a pus destroyer, and, being unirritating, may be poured upon pus-bathed surfaces or into the body cavities, when prompt effervescence will ensue, with the liberation of oxygen, and when the commotion has ceased, the cavity will be free from pus. Ordinarily the agent causes no pain, but in small cavities, as in the ear, nasal fossæ, and urethra, the sudden distension of the parts by the rapid evolution of the gas may occasion pain, if not other injury, to the parts. It is applicable to all forms of *wounds* and *ulcerations* as a local disinfectant and antiseptic. *Putrid surfaces* and *discharges* call for it. Pus cells are found to shrivel, become granular, and break down after having been in contact with the solution. It promptly destroys many of the *bacteriæ*. *Syphilitic chancre* is said to be destroyed by it, but this is probably claiming too much for it. It does, however, improve the condition of *syphilitic ulcers*, as well as those of a tuberculous or scrofulous character. *Mammary abscesses* may be cleansed with it, and it may be poured or injected into other *abscesses*, *sinuses*, *fistulæ*, and upon sluggish, *fetid ulcerations* and *carbuncles*. As a spray it may be used in an atomizer upon the membranes of the throat and nose, and especially where fetor and pus are present, in *ulcerative tonsillitis*, *scarlatinal angina*, *ozæna*, *chronic nasal catarrh*, and in *fetid bronchial secretions* and *fetid breath* from local causes. In *diphtheria* it has been highly valued, and particularly after the membrane has become detached. In this disease the remedy should also be given internally in teaspoonful doses of a

15-volume solution (100 parts) mixed with glycerin (1½ parts). Owing to its bleaching properties it has been successfully used to remove *morph*.

In the puerperal state when the lochia becomes putrid and the temperature leaps high, and there is great excitation, the ushering in of a *puerperal septicæmia*, no better cleansing agent can be used than solution of hydrogen dioxide. With appropriate remedies it will greatly assist in preventing a fatal issue. In *gonorrhæa*, *leucorrhæa*, *cystitis*, and other genito-urinary states in which pus is contained in the secretions, it makes a safe and efficient wash. In *purulent conjunctivitis* it quickly destroys the pus, and irrigation of the sac in *dacrocystitis* is often followed by a prompt cure. Foltz states that he has been disappointed with it in the *suppurative diseases of the ear* in which it has been so highly praised. With him the "dry treatment" has yielded prompter results. The *stings* of insects are rendered painless by spraying the solution upon the parts.

Hydrogen peroxide is on the market in 10 and 15 volume solutions in water. Of the 10-volume preparation from 1 to 4 fluid drachms largely diluted may be given internally 3 times a day after meals; as a spray and gargle take 2 fluid ounces of the 15-volume solution in 14 ounces of water; for other local uses, a wash of from 3 to 10 fluid ounces of the 10 or 15 volume peroxide to 16 fluid ounces of water.

Related Substances.—OZONE (see *Ozone*) has been proposed as a disinfectant of the air, but it has been shown that before pathogenetic bacteria and other low forms of life are affected by it, the atmosphere must be so saturated with it as to render it irrespirable.

OZONIC ETHER.—A fairly stable, but very inflammable solution of hydrogen dioxide in ether, introduced by Richardson and used as an internal agent.

HYDROZONE.—Manufactured by Charles Marchand, Chemist, of New York City. It is a concentrated preparation of preserved hydrogen peroxide, containing 9 per cent of anhydrous hydrogen dioxide (H_2O_2), and yields not less than 30 volumes of available nascent oxygen. It has a feebly acid taste, and should not be neutralized before using. With ordinary care it does not lose more than $\frac{1}{4}$ of 1 volume every 30 days, at a temperature not exceeding 21.1° C. (70° F.); therefore it is quite a stable preparation. It is intended for use in the same conditions for which hydrogen peroxide is valued, but on account of its high degree of concentration is best adapted when an immediate and more decided antiputrefactive and germicidal agent is required.

GLYCOZONE.—Manufactured by Charles Marchand, Chemist, New York City. It is a stable chemical compound resulting from the chemical reaction which takes place when C. P. glycerin is submitted to the action of 15 times its own volume of ozone. It has a pleasant, sweet, acidulous taste. It absorbs moisture quite rapidly, therefore, it must be kept in well-stoppered containers, to avoid deterioration. Changes do not take place in it below 43.3° C. (110° F.). When tightly corked, so as to retain its anhydrous condition, its healing properties increase with age. It acts similarly but less promptly than hydrozone. In *gastric disorders* it is preferred on account of its kindlier action. It is not poisonous, but it should never come in contact with metallic utensils, like syringes, as it is decomposed thereby. Glass or rubber syringes must be employed. It is successfully applied externally and topically to the throat, rectum, and vagina. Internally it is valued in gastric disorders, being given in 1 or 2 drachm doses in a wineglassful of water, on an empty stomach. In *atonic* and *acid dyspepsia*, *gastric catarrh* and similar affections, it should be given immediately after meals.

AQUA LAUROCERASI.—CHERRY-LAUREL WATER.

Preparation.—Aqua Laurocerasi is prepared, according to the *British Pharmacopœia* (1867), as follows: "Take of fresh leaves of cherry-laurel, 1 pound; water, 2½ pints (50 fl̄); chop the leaves, crush them in a mortar, and macerate them in the water for 24 hours; then distill 1 pint (20 fl̄) of liquid; shake the product, filter through paper, and preserve it in a stoppered bottle"—(*Br.* 1867).

The *French Codex* employs cherry-laurel leaves, ten grammes (10 Gm.) [155 grs.]; water, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; and by a moderate fire distills until fifteen grammes (15 Gm.) [231 grs.] have passed over. The proportion of hydrocyanic acid contained in the cherry-laurel water is determined by means of a titrated solution of cupric sulphate, containing 23.09 Gm. (356 grs.) of this salt, in crystals, to one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M] of distilled water. The process is as follows: A flat-bottomed glass beaker is placed upon a sheet of white paper, and 10 Cc. cherry-laurel water, with 1 Cc. of aqua ammoniæ, are poured into it. The titrated cupric solution is placed into a burette divided into tenths of a cubic centimeter, from which it is

gradually dropped into the liquid in the beaker, and, as soon as the blue coloration is maintained, the number of divisions read upon the burette of the cupric fluid employed, will give exactly, in milligrammes, the proportion of hydrocyanic acid contained in 10 Cc. of the cherry-laurel water experimented with. In this country, cherry-laurel water is often substituted by oil of bitter almond water; as that which is imported is quite variable in strength. In 1875, Mr. W. A. Tilden examined 2½ ounces of the oil that rose upon the surface of cherry-laurel water, and concluded that it consisted chiefly of bitter almond oil, accompanied with less than 2 per cent of hydrocyanic acid, a small portion of another volatile oil, and traces of an odorous resin. Mr. Beringer, in 1890, called attention to commercial specimens containing magnesia, undoubtedly due to preparing the water, not by distillation, but by trituration of the essential oil with magnesia and water (*Amer. Jour. Pharm.*, 1890).

Action, Medical Uses, and Dosage.—This water is employed in the same conditions and maladies as those in which hydrocyanic acid is indicated, in doses of from 5 to 30 minims, administered with prudence and caution; but on account of its uncertain strength it is rarely used in this country, bitter almond water being preferred, as it can readily be prepared as wanted for use (see also *Aqua Amygdalæ Amaræ*).

AQUA MENTHÆ PIPERITÆ (U. S. P.)—PEPPERMINT WATER.

Preparation.—"Oil of peppermint, two cubic centimeters (2 Cc.) [32 M]; precipitated calcium phosphate, four grammes (4 Gm.) [62 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Triturate the oil of peppermint with the precipitated calcium phosphate, add the distilled water gradually, under constant trituration, and filter"—(U. S. P.).

Action, Medical Uses, and Dosage.—Peppermint water is used as an antispasmodic and carminative, in *flatulence* and *flatulent colic*, to allay *nausea* and *vomiting*, and as a gentle aromatic stimulant. The dose is from 4 fluid drachms to 2 fluid ounces, 3 or 4, or more times a day.

AQUA MENTHÆ VIRIDIS (U. S. P.)—SPEARMINT WATER.

Preparation.—"Oil of spearmint, two cubic centimeters (2 Cc.) [32 M]; precipitated calcium phosphate, four grammes (4 Gm.) [62 grs.]; distilled water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Triturate the oil of spearmint with the precipitated calcium phosphate, add the distilled water gradually, under constant trituration, and filter"—(U. S. P.).

Action, Medical Uses, and Dosage.—Similar to those of peppermint water, to which some persons prefer it. The dose is also the same. It is a useful vehicle for potassium acetate and other diuretics.

AQUÆ MINERALES.—MINERAL WATERS.

MINERAL WATERS (*Aquæ Minerales*) are those which present a large proportion of carbonic acid gas, with or without saline, alkaline, metallic, earthy, gaseous, and other foreign substances, and which exert an appreciable therapeutical influence on the animal economy. The chemical ingredients most frequently present are chloride of sodium, carbonates of sodium and of iron, sulphates of sodium, of magnesium, and of calcium, iodide of sodium, sulphide of hydrogen, carbon dioxide, oxygen and nitrogen. Less frequently found are arsenic compounds, lithium salts, bromide of sodium, free sulphuric acid, fluorides, and organic compounds. The ingredient in excess, or that having the most pronounced action, usually determines the classification. Space permits but a brief notice of a few of the most important mineral springs of this country and Europe. In the United States there are upwards of 250 mineral springs possessing reputed

medicinal properties. Many of the springs in this country, if not the majority, are the counterpart of those of Europe. For all practical purposes, they may be appropriately divided into *acidulous*, *chalybeate* or *ferruginous*, *sulphurous*, and *saline mineral waters*, etc. When the water is elevated in temperature the springs are called *Hot* or *Thermal*; when of ordinary temperature or lower, they are called *Cold Mineral Springs*.

I. **ACIDULOUS WATERS** are not so frequently met with as the other forms of mineral waters, from which they are distinguished by holding in solution a *free acid*, other than the carbonic. *Oak Orchard Springs* (Genesee Co., N. Y.), is a representative sulphuric acid spring, containing in a quart, besides sulphates of calcium, iron, magnesium, aluminum and silica, 20.74 grains of free sulphuric acid. Free sulphuric acid is stated, likewise to exist in the *Alum Springs* of Virginia.

II. **CHALYBEATE WATERS** (*Ferruginous Waters*) contain iron (usually as a bicarbonate, occasionally as a sulphate) as their active principle, and in considerable proportion; they have a styptic taste, and become purplish-black with tannic or gallic acids. When the water contains ferrous salts, the addition of ferrocyanide of potassium causes a white precipitate, which on exposure to the air becomes blue; when the higher salts of iron are contained in the water, ferrocyanide of potassium gives a blue precipitate, and sulphocyanide of potassium, a red one. Chalybeate waters are divided into *carbonated* and *sulphuretted*; the former being brisk, sparkling, and acidulous, the latter containing hydrogen sulphide. To be of first quality these waters should contain considerable iron and but little of other mineral ingredients, and should be highly carbonated.

A representative spring of this type is *Schooley's Mountain* (Morris Co., N. J.), temperature 10° C. (50° F.). *Rawley Springs* (Rockingham Co., Va.), and *Cooper's Well* (Hinds Co., Miss.), are also typical. European springs of this class are represented by *Spa* (Germany), temp. 10° C. (50° F.); *Brighton* (England); *Cheltenham* (chalybeate) (England), temp. 11.1° to 11.6° C. (52° to 53° F.); *Pyrmont* (Germany), and *Schwalbach* (Germany), the latter being one of the strongest of chalybeate waters. *Anderson's Spring* (Bedford, Pa.), temp. 13.3° to 14.4° C. (56° to 58° F.), and *Ballston Spa* (N. Y.), temp. 10° to 12.2° C. (50° to 54° F.), are sometimes classed with the chalybeate springs. The *Tunbridge Wells* (England), are celebrated as iron springs.

III. **SULPHUR** (*Sulphuretted*) **WATERS** are impregnated with hydrogen sulphide, and other sulphides and nitrogen, in consequence of which they have an odor resembling that of rotten eggs. They react upon many metallic salts, causing black precipitates. They are frequently divided into *muriated alkaline*, and *calcic sulphur waters*. They are also divided into *cold* and *thermal sulphur springs*. Some of these waters are designated according to the color of the deposits yielded by the escaping water, as *white* (sulphur), *red* (oxide of iron, or microscopic algæ), *blue* (slate), or *yellow* (polysulphides) *sulphur waters*. This class of waters is largely represented in the United States, but not all of them are decidedly medicinal. In Europe, among the chief cold springs are: *Harrowgate Old Well* (England); *Montmorency* (France); *Nenndorf*, *Langenbrücken*, and *Meinberg* (Germany). Of the thermal springs are: *Aix-la-Chapelle* (Germany), three springs, the temperature of which ranges from 43.3° to 61.6° C. (110° to 143° F.); *Aix-les-Bains* (Savoy); *St. Sauveur*, *Barèges*, *Bagnères-de-Luchon*, and *Eaux-Chaudes* (France); and *Baden* (near Vienna). In the United States the muriated sulphur springs are represented by the *Columbia* (N. Y.); *Louisville Artesian* (thermal); *Upper* and *Lower Blue Lick*, *Big Bone Springs*, *Paroquet*, *Olympian Springs*, of Kentucky; *Massena Springs* (St. Lawrence Co., N. Y.); and *Salt Sulphur* (Monroe Co., W. Va.). The last named, together with *Sharon Springs* (White Sulphur and Magnesian Springs) (N. Y.), *French Lick* (Orange Co., Ind.), *Greenbrier White Sulphur* (Va.), contain purgative, or purgative and calcic salts. The *Red Sulphur Springs* (W. Va.) contain also a sedative organic principle termed *hydrosin* or *barégine*. *Borden Spring* (W. Va.) is sulpho-alkali-saline and purgative. *Yellow Sulphur* (Va.), and *Clifton* and *Chittenango* (N. Y.), are calcic sulphur springs. The *White*, temp. 16.6° C. (62° F.); the *Red*, temp. 12.7° C. (55° F.); and *Blue Sulphur Springs*, are noted Virginian springs. The most noted American thermal sulphur waters are those of *Calistoga* (about 60 springs), *Santa Barbara*, temp.

15.5° to 54.4° C. (60° to 130° F.), *Paso Robles*, temp. 44.4° to 50° C. (112° to 122° F.), all of California; *Middle Park* (Colo.), temp. 43.8° to 46.6° C. (111° to 116° F.); *Warm Springs* (Ga.), temp. 32.2° C. (90° F.); *Warm Springs* (Va.), temp. 35.5° to 36.6° C. (96° to 98° F.). Near Sitka, Alaska, are the celebrated *Warm Sulphur Springs* or *Geysers*, temp. 35.5° to 40° C. (96° to 104° F.).

IV. SALINE WATERS owe their medicinal activity to their saline ingredients, as various salts of sodium, magnesium, calcium, potassium, etc.; and the sulphates, chlorides, and carbonates are the most common. The principal constituent is sodium chloride. They usually contain small portions of iron, and often a large amount of carbonic acid, and occasionally iodine or bromine. They are divided into *Salt* (*Muriated*), *Calcic* (*Calcareous*), and *Silicious Waters*. The most agreeable of these waters are the *mild saline* or *muriated waters*, best represented in this country by the *Saratoga Springs*, temp. 9.4° to 10.5° C. (49° to 51° F.), with few exceptions (some being *muriated-chalybeate*, as *Hamilton*, *Columbian*, and *Pavilion Springs*), *Charleston* (S. C.), *Albany Artesian Wells* (N. Y.), and *Ballston Spa*. The *Hot Springs of Virginia*, temp. 35.5° to 41.6° C. (96° to 107° F.), are representative American alkaline-saline springs. In Europe the following are celebrated: *Selters*, *Apollinaris*, *Bath* (England), temp. 44.4° to 46.6° C. (112° to 116° F.); *Cheltenham Saline Springs* (England), temp. 11.1° to 12.2° C. (52° to 54° F.); *Carlsbad* (Bohemia), temp. 73.8° C. (165° F.); *Sprudel* and *Plombières* (France) 32.2° to 62.7° C. (90° to 145° F.). Among the calcic springs of note are: *Eaton Rapids Wells* (Mich.); *Sweet Springs* (Monroe Co., W. Va.), temp. 23.3° C. (74° F.); *Bethesda* (Waukesha, Wis.), temp. 15.5° C. (60° F.), calcic alkaline; *Yellow Springs* (Greene Co., O.), and *Gettysburg* (Adams Co., Pa.). Calcic springs are rich in limestone (calcium carbonate) and gypsum (calcium sulphate) mixed with saline and alkaline salts and some iron. Some Canadian Waters, as of the *Plantagenet* and *Caledonia*, are good examples of iodo-bromated saline waters.

SEA WATER.—The proportions of the contents of sea water, as found by Schweitzer, who analyzed the water of the English Channel, are about as follows: Water, parts 29235.424+; sodium chloride 895.72+; potassium chloride 23.48+; magnesium chloride 111.12+; magnesium bromide 0.878+; magnesium sulphate 68.81; calcium sulphate 42.6+; calcium carbonate 1.0.

V. ALKALINE WATERS.—In these waters, sodium, potassium, and magnesium carbonates predominate, the most noted of this class being those of *Vichy* (France), temp. of the various springs ranging from 23.8° to 46.1° C. (75° to 115° F.). In Germany they are represented by such springs as *Ems*, *Fachingen*, *Salzbrunn*, etc.; in England, by *Buxton* and *Bristol*; *Camarès* in France; and in this country by the *Bladon Springs* of Choctaw Co., Alabama.

VI. PURGATIVE WATERS.—These waters include those having purgative or aperient properties due to the presence of sulphates of magnesium, sodium, and potassium, modified by the presence of alkaline or calcic sulphates and carbonates, or some chalybeate compound. They constitute the *Bitterwasser* (bitter water) of the Germans. Some of them are highly carbonated. European waters of this class are those of *Seidlitz* (Bohemia), temp. 15° C. (59° F.); *Friedrichshall* (in Saxe-Meiningen); *Kissingen*, *Püllna*, *Hunyadi János*, *Epsom* (England); *Ivándá* (Hungary); and *Champagne-sur-Aude* (France). American purgative waters are represented by the *Crab Orchard Springs* (Lincoln Co., Ky.); *Harrodsburg* (Mercer Co., Ky.) (containing also calcium sulphate and iron carbonate); *Estill* (*Irvine Springs* (Estill Co., Ky.); and *Bedford Springs* (Bedford, Pa.), the latter being a purgative-chalybeate water.

VII. SILICIOUS WATERS.—As already remarked, these are a division of the saline waters, which are occasionally met with. The *boiling springs of Geyser*, in Iceland, belong to this division, the silica being held in solution by the sodium compounds present.

VIII. CARBONATED WATERS.—Formerly the carbonated waters were recognized as a separate class. They include, however, many of the waters named in the other classes. They owe their qualities to carbonic acid gas, which gives them more or less of an acidulous taste, a briskness, a sparkling property, and an acid reaction. In this class were formerly included such springs as *Seltz* or *Seltzer* (Germany); *Pyrmont* (Germany); *Spa* (Belgium); *Mont d'Or* (France), including 4 springs: *St. Marguerite's*, the temperature of which is 10° to 12.2° C. (50° to

54° F.), the *Grand Bath*, temp. 43.3° C. (110° F.), *Cæsar's Baths*, temp. 45° C. (113° F.), *La Magdelaine*, temp. 42.2° C. (108° F.); *Vichy* (France); *Sweet Springs* (Va.), etc. They are cooling, refreshing, and exhilarating, and frequently relieve nausea. They usually hold in solution ferrous carbonate, or the carbonates of one or more of the alkaline earths. Carbonated waters are contraindicated in acute diseases and in plethoric persons.

IX. THERMAL WATERS.—The indifferent thermal waters contain but small amounts of inorganic compounds, and are valuable chiefly on account of their elevated temperature, 23.8° to 71.1° C. (75° to 160° F.). The noted American springs of this type are represented by the *Hot Springs* (Ark.), numerous springs ranging in temperature from 33.8° to 65.5° C. (93° to 150° F.); *Hot Springs* (Va.), temp. 25.5° to 43.3° C. (78° to 110° F.); *Warm Springs* (Va.), temp. 36.6° C. (98° F.); *Healing Springs* (Bath Co., Va.); *Lebanon Springs* (Columbia Co., N. Y.). The *Idaho Hot Springs*, temp. 29.4° to 46.1° C. (85° to 115° F.); *Warm Springs* (N. C.), temp. 36.1° to 38.8° C. (97° to 102° F.); and *Paso Robles* (Cal.), temp. 44.4° to 50° C. (112° to 122° F.), are thermal springs not belonging to the indifferent class, but containing several active constituents. Noted European thermal waters are those of *Plombières* (France), temp. 51.6° C. (125° F.); *Gastein* (Salzburg, in Austria), temp. 30.5° to 71.1° C. (87° to 160° F.); *Teplitz* (Bohemia), temp. 48.8° C. (120° F.), etc.

Action and Medical Uses.—Mineral waters vary in their effects upon the system, according to their constituent combination. Added to their intrinsic value, when properly employed, the change of climate and habits, the hygienic influences, the abandonment of business and social cares, the pleasant associations, and various other aids, undoubtedly contribute largely to the successful treatment of chronic diseases as pursued at the various mineral springs. Injudiciously used, mineral waters are, of course, as liable to do mischief as is the injudicious employment of medicines. The uses of the various classes of mineral waters can be but briefly referred to in this article, as follows:

I. ACIDULOUS WATERS.—The acidulous waters are powerful and diffusible stimulants of the nervous and circulatory system, likewise diuretic. Generally useful in *dyspepsia*, *passive dropsy*, *chronic diseases*, *chlorosis*, and *phosphatic gravel*; contraindicated in recent palsy, apoplexy, and active hemorrhages and inflammations.

II. CHALYBEATE WATERS.—Chalybeate waters are tonic and restorative, and used in *anemia*, *chlorosis*, *dyspepsia*, all kinds of *chronic cachexia*, *gout*, *diabetes*, *leucorrhæa*, *chronic diarrhæa*, and chronic diseases generally, especially those attended with excessive mucous and other discharges, and those not attended with plethora, fever, or inflammation. Their use blackens the stools. They increase the appetite, and improve digestion, give increased cardiac action, and improve the quality of the blood, particularly in anemic individuals.

III. SULPHUR WATERS.—Sulphurous waters are stimulant, diaphoretic, diuretic, and emmenagogue, and are found beneficial in *chlorosis*, *gout*, *rheumatism*, *dysmenorrhæa*, *secondary syphilis*, *chronic cutaneous diseases*, *hemorrhoids*, and *deranged conditions of the stomach and liver*. They are contraindicated in plethora, determination to the head, and active hemorrhages and inflammations. Waters which contain iodine or bromine, have been found of some use in *goitre* and *scrofula*. For *rheumatic*, *gouty*, and *syphilitic* individuals, the thermal sulphur waters are most effective, while for *pulmonary* and other forms of *catarrhal diseases*, the cold sulphur waters are preferable. These waters are especially adapted to chronic metallic poisoning, as *lead poisoning*, and *mercurial cachexia*.

IV. SALINE WATERS.—Saline waters are diuretic and aperient, particularly useful in *chronic constipation*, *dyspepsia*, with *hepatic sluggishness*, *jaundice*, *biliary catarrh*, *gall-stones*, *urinary calculi*, *rheumatism* (when alkalies are indicated), and *gout*, especially if anemic, and in *uterine* and *renal irritability*, and *passive congestion* of these parts. *Abdominal plethora* in the robust, is benefited by these waters. Saline baths have benefited *hemiplegia* and *paraplegia* in the early stages.

CALCIC WATERS are valuable in *chronic cystitis*, with irritability, *urinary calculi*, *diabetes mellitus*, and painful forms of *dyspepsia*.

SEA WATER.—Sea water internally is an emetic and purgative; as a bath it has all the effects of an ordinary cold bath, with the addition of exerting a more

stimulant action on the skin than fresh water, owing to its saline contents. It has been found serviceable in *rickets*, enlargement of glands or joints, some chronic cutaneous eruptions, *scrofula*, and many chronic diseases.

V. ALKALINE WATERS.—Alkaline waters are antacid, antilithic, and diuretic. They may be used for the same conditions as the saline waters, being particularly useful in *gout*, *uric acid gravel*, *urinary* and *hepatic calculi*, certain skin diseases, *chronic gastritis*, and *saccharine diabetes*.

VI. PURGATIVE WATERS.—Purgative waters also possess diuretic properties, and are useful in small doses in all cases where laxatives, and, in larger doses, purgation are required. They are particularly of value in *corpulency*, *hepatic engorgement*, *constipation*, and *abdominal plethora*, especially when due to intemperance in eating and drinking.

VII. SILICIOUS WATERS.—Silicious waters are of value chiefly in chronic affections of the osseous and ligamentous structures.

VIII. THERMAL WATERS.—Thermal waters are chiefly curative by virtue of their uniform heat, and valued mostly as aids to medicines in the treatment of various chronic disorders by means of baths. They are largely resorted to for the cure of skin affections, such as *lichen*, *psoriasis*, various ulcerations, old wounds, *enervated conditions*, *hysteria*, *acute* and *chronic articular* and *muscular rheumatism*, *gout*, *false ankylosis*, *paraplegia*, *gastralgia*, etc. They are largely resorted to as an aid in curing *syphilis*.

Artificial Mineral Water Preparations.—SAL CAROLINUM FACTITUM (N. F.). *Artificial Carlsbad salt*. *Formulary number*, 336: "I. In a dry, amorphous form (*Ger. Pharm.*).—Potassium sulphate twenty grammes (20 Gm.) [309 grs.]; sodium chloride one hundred and eighty grammes (180 Gm.) [8 ozs. av., 153 grs.]; sodium bicarbonate three hundred and sixty grammes (360 Gm.) [12 ozs. av., 306 grs.]; sodium sulphate (dried) four hundred and forty grammes (440 Gm.) [15 ozs. av., 228 grs.]. Triturate the ingredients, previously well dried, to a fine, uniform powder.

"*Note.*—The dried sodium sulphate is prepared by slowly drying the crystalline salt until it has lost one-half of its weight.

"II. In a crystalline form.—Potassium sulphate twenty grammes (20 Gm.) [309 grs.]; sodium chloride one hundred and eighty grammes (180 Gm.) [8 ozs. av., 153 grs.]; sodium carbonate (in clear crystals) six hundred and ten grammes (610 Gm.) [1 lb. av., 5 ozs., 226 grs.]; sodium sulphate (crystallized) eight hundred and eighty grammes (880 Gm.) [1 lb. av., 15 oz., 18 grs.]; distilled water five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]. Dissolve the potassium sulphate and sodium chloride in the distilled water, and add this solution to the other two salts, previously melted in a tared capsule and at a gentle heat in their own water of crystallization. Evaporate the mixture to about 1800 Gm. [3 lbs. av., 15 ozs., 217 grs.], set it aside in a cool place, and stir frequently, so as to prevent the formation of large crystals, taking care, however, that none of the salt separate in a pulverulent form. Distribute any remaining water of crystallization uniformly over the crystals, and dry the whole mixture sufficiently by exposure to air, so that it will retain its crystalline character. A solution of about 16 grains of the dry, or about 27 grains of the crystalline salt, in 6 fluid ounces of water, represents an equal volume of Carlsbad water (*Sprudel*) in its essential constituents.

"*Note.*—The salts employed in the preparation of the crystalline form must have been purified by recrystallization" (*Nat. Form.*).

PULVIS SALIS CAROLINI FACTITII EFFERVESCENS (N. F.). *Effervescent powder of artificial Carlsbad salt*. *Formulary number*, 331: "Effervescent artificial Carlsbad salt.—Artificial Carlsbad salt (F. 336), (in form of dry powder) one hundred and eighty grammes (180 Gm.) [8 ozs. av., 153 grs.]; saccharated sodium bicarbonate (F. 341) four hundred and ten grammes (410 Gm.) [14 ozs. av., 202 grs.]; saccharated tartaric acid (F. 8) four hundred and ten grammes (410 Gm.) [14 ozs. av., 202 grs.]. Mix the ingredients, previously well dried, and triturate them until a uniform powder is obtained. To make *Granular effervescent artificial Carlsbad salt*, substitute saccharated citric acid (F. 5), (not dried) two hundred and five grammes (205 Gm.) [7 ozs. av., 101 grs.] for an equal weight of the saccharated tartaric acid, and prepare the granulated compound as directed under the general formula (F. 319, B.). A solution of about 87 grains of this preparation, in 6 fluid ounces of water, represents an equal volume of Carlsbad water (*Sprudel*), in its essential constituents" (*Nat. Form.*).

SAL KISSINGENSE FACTITUM (N. F.). *Artificial Kissingen salt*. *Formulary number*, 337: "Potassium chloride seventeen grammes (17 Gm.) [262 grs.]; sodium chloride three hundred and fifty-seven grammes (357 Gm.) [12 ozs. av., 259 grs.]; magnesium sulphate (anhydrous) fifty-nine grammes (59 Gm.) [2 ozs. av., 36 grs.]; sodium bicarbonate one hundred and seven grammes (107 Gm.) [3 ozs. av., 338 grs.]. Triturate the ingredients, previously well dried, to a fine, uniform powder. A solution of about 24 grains of this preparation, in 6 fluid ounces of water, represents an equal volume of Kissingen water (*Rabocsi spring*) in its essential constituents" (*Nat. Form.*).

PULVIS SALIS KISSINGENSIS FACTITII EFFERVESCENS (N. F.). *Effervescent powder of artificial Kissingen salt*. *Formulary number*, 332: "Effervescent artificial Kissingen salt.—Artificial Kissin-

gen salt (F. 337) two hundred and eighty grammes (280 Gm.) [9 ozs. av., 384 grs.]; saccharated sodium bicarbonate (F. 341) three hundred and sixty grammes (360 Gm.) [12 ozs. av., 306 grs.]; saccharated tartaric acid (F. 8) three hundred and sixty grammes (360 Gm.) [12 ozs. av., 306 grs.]. Mix the ingredients, *previously well dried*, and triturate them until a uniform powder is obtained. To make *Granular effervescent artificial Kissingen salt*, substitute saccharated citric acid (F. 5), (*not dried*) one hundred and eighty grammes (180 Gm.) [6 ozs. av., 153 grs.], for an equal weight of the saccharated tartaric acid, and prepare the granulated compound as directed under the general formula (F. 319, B.). A solution of about 80 grains of this preparation, in 6 fluid ounces of water, represents an equal volume of Kissingen water (*Rabotzi springs*) in its essential constituents" (*Nat. Form.*).

SAL VICHYANUM FACTITIUM (N. F.). *Artificial Vichy salt*. *Formulary number*, 338: "Sodium bicarbonate eight hundred and forty-six grammes (846 Gm.) [1 lb. av., 13 ozs., 366 grs.]; potassium carbonate thirty-eight and one-half grammes (38.5 Gm.) [1 oz. av., 157 grs.]; magnesium sulphate (anhydrous) thirty-eight and one-half grammes (38.5 Gm.) [1 oz. av., 157 grs.]; sodium chloride seventy-seven grammes (77 Gm.) [2 ozs. av., 313 grs.]. Triturate the ingredients, *previously well dried*, to a fine, uniform powder. A solution of about 14 grains of this preparation, in 6 fluid ounces of water, represents an equal volume of Vichy water (*Grande Grille spring*) in its essential constituents" (*Nat. Form.*).

PULVIS SALIS VICHYANI FACTITH EFFERVESCENS (N. F.). *Effervescent powder of artificial Vichy salt*. *Formulary number*, 333: "*Effervescent artificial Vichy salt*.—Artificial Vichy salt (F. 338) two hundred and forty grammes (240 Gm.) [8 ozs. av., 204 grs.]; saccharated sodium bicarbonate (F. 341) three hundred and eighty grammes (380 Gm.) [13 ozs. av., 134 grs.]; saccharated tartaric acid (F. 8) three hundred and eighty grammes (380 Gm.) [13 ozs. av., 178 grs.]. Mix the ingredients, *previously well dried*, and triturate them until a uniform powder is obtained. To make *Granular effervescent artificial Vichy salt*, substitute saccharated citric acid (F. 5), (*not dried*) one hundred and ninety grammes (190 Gm.) [6 ozs. av., 307 grs.], for an equal weight of the saccharated tartaric acid, and prepare the granulated compound as directed under the general formula (F. 319, B.). A solution of about 57 grains of this preparation, in 6 fluid ounces of water, represents an equal volume of Vichy water (*Grande Grille spring*) in its essential constituents" (*Nat. Form.*).

PULVIS SALIS VICHYANI FACTITH EFFERVESCENS CUM LITHIO (N. F.). *Effervescent powder of artificial Vichy salt with lithium*. *Formulary number*, 334: "*Effervescent artificial Vichy salt with lithium*.—Artificial Vichy salt (F. 338) one hundred and fifty-six grammes (156 Gm.) [5 ozs. av., 220 grs.]; lithium citrate (in very fine powder) fifty-six grammes (56 Gm.) [1 oz. av., 427 grs.]; saccharated sodium bicarbonate (F. 341) three hundred and ninety-four grammes [394 Gm.] [13 ozs. av., 393 grs.]; saccharated tartaric acid (F. 8) three hundred and ninety-four grammes (394 Gm.) [13 ozs. av., 393 grs.]. Mix the ingredients, *previously well dried*, and triturate them until a uniform powder is obtained. To make *Granular effervescent artificial Vichy salt with lithium*, substitute saccharated citric acid (F. 5), (*not dried*) one hundred and ninety-two grammes (192 Gm.) [6 ozs. av., 338 grs.] for an equal weight of the saccharated tartaric acid, and prepare the granulated compound as directed under the general formula (F. 319, B.). 90 grains (or about a heaped teaspoonful) of this preparation represent 14 grains of artificial Vichy salt and 5 grains of lithium citrate" (*Nat. Form.*).

AQUA PICIS LIQUIDÆ.—TAR WATER.

Preparation.—Take of tar, 2 pints; boiling water, 1 gallon. Mix together and stir with a wooden rod for 15 minutes. When cold, and the tar has subsided, strain the liquor and keep it in well-stoppered bottles (*Dub.*). The *German Pharmacopœia* prepares it by mixing with previously washed and dried pumice stone (3 parts), tar (1 part). Of this mixture add 2 parts to 5 parts of water, shake well for 5 minutes and filter. It forms a clear yellow or yellow-brown fluid.

Description, Medical Uses, and Dosage.—Tar water has a Madeira-wine color, and a sharp, empyreumatic taste; it reddens litmus, but does not effervesce with carbonate of potassium, though it becomes more darkly colored. Persulphate of iron blackens it. It consists of water, holding in solution acetic acid, resin, and pyrogenous oil. Tar water exerts a mild influence on mucous membranes, and hence has been found useful in *chronic catarrhal* and *urinary affections*, in doses of 1 or 2 pints daily. Sometimes tar water is prepared, with the addition of honey, for *pulmonary affections*. Externally, it has been found useful as a wash in *diseases of the scalp*, and other *chronic affections of the skin*. The usual dose is from $\frac{1}{2}$ to 1 fluid ounce.

AQUA PIMENTÆ.—PIMENTO WATER.

Preparation.—Take of pimento, bruised, 14 ounces; water, 2 gallons. Mix them, and distill 1 gallon—(*Br.*). Or it may be prepared in the same manner

as cinnamon water, on page 247, using oil of pimento instead of oil of cinnamon. A brownish resin separates on standing.

Action, Medical Uses, and Dosage.—Used in *flatulency* and *weak digestion*, in doses of 1 or 2 fluid ounces.

AQUA ROSÆ (U. S. P.)—ROSE WATER.

SYNONYM: *Aqua rosarum*.

Preparation.—"Stronger rose water, distilled water, of each 1 volume. Mix them immediately before use"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Rose water forms an agreeable, cooling, unirritating, and slightly astringent collyrium, which is useful in many affections of the eye; it is also added to lotions, washes, etc., to impart an agreeable perfume. It enters into the official *Unguentum Aquæ Rosæ*.

AQUA ROSÆ FORTIOR (U. S. P.)—STRONGER ROSE WATER.

SYNONYMS: *Aqua rosæ* (*Pharm.*, 1880), *Triple rose water*.

Source and Tests.—Water saturated with the volatile oil of rose petals, obtained as a by-product in the distillation of oil of rose. Stronger rose water should be kept in well-stoppered bottles, in a dark place. Stronger rose water should be colorless and clear, not mucilaginous, and give no reaction with hydrogen sulphide or ammonium sulphide T.S. (absence of metallic impurities).

Use.—Used in the preparation of *Rose Water*.

AQUA SAMBUOI.—ELDER-FLOWER WATER.

Preparation.—To fresh elder flowers, 12 pounds, add water, 2 gallons. Distill 1 gallon. The *Br. Pharm.* directs 10 pounds of the fresh flowers freed from the stalks (or an equal weight of flowers preserved, while still fresh, with salt), to 5 gallons of water, to produce 1 gallon (Imp.) of elder-flower water.

Action, Medical Uses, and Dosage.—But little oil is contained in elder flowers; the water distilled from them is sometimes used in collyria and other lotions. It is more extensively employed in England than in America. According to Mr. Haselden, the water distilled from elder flowers is better, when the flowers have been previously mixed or beaten with half their weight of chloride of sodium, as it tends to preserve them much longer from decomposition. The dose (usually as an excipient) is from 1 to 2 fluid ounces.

AQUA SEDATIVA (N. F.)—SEDATIVE WATER.

SYNONYMS: *Lotio ammoniacalis camphorata* (*Codex*), *Eau sédative de Raspail*. *Formulary number*, 11.

Preparation.—"Water of ammonia (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄3, 109 M]; spirit of camphor (*U. S. P.*), twelve cubic centimeters (12 Cc.) [195 M]; sodium chloride, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. Dissolve the sodium chloride in about five hundred cubic centimeters (500 Cc.) [16 fl̄3, 435 M] of water, add the water of ammonia and spirit of camphor, and finally enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. Shake the liquid when it is to be dispensed"—(*Nat. Form.*).

Raspail's *Eau Sédative* was formerly made as follows; three strengths being indicated:

	No. 1.	No. 2.	No. 3.
Take of solution of ammonia (22°)	60 parts.	80 parts.	100 parts.
Tincture of camphor	10 "	10 "	10 "
Common salt	60 "	60 "	60 "
Water	1000 "	1000 "	1000 "

Dissolve the common salt in the water, then mix the camphor and ammonia together, and add them to the saline solution.

Action, Medical Uses, and Dosage.—Stimulant, sedative, and anodyne. It is employed in *hemicrania*, *cerebral congestion*, and *rheumatic affections*, and is applied by compresses to the affected part; and when near the eyes, care should be taken to protect them. No. 1 is for persons whose skins are easily irritated; No. 2 for allaying the pain from the *stings of insects*; and No. 3 for persons having a hard and callous skin.

ARALIA HISPIDA.—DWARF ELDER.

The bark of the root of the *Aralia hispida*, Linné.

Nat. Ord.—Araliaceæ.

COMMON NAMES: *Dwarf elder*, *Wild elder*, *Bristle-stem sarsaparilla*.

Botanical Source.—*Aralia hispida* is a perennial plant, with a low stem, from 1 to 2 feet high, the lower part woody and shrubby, thickly beset with sharp stiff bristles, the upper part herbaceous and branching. The leaves are bipinnate, and composed of oblong-ovate, acute, cut-serrate leaflets. The flowers, which are greenish-white, are arranged in numerous umbels which are simple, globose, axillary, and terminal, on long peduncles, and followed by bunches of dark-colored, nauseous berries. It flowers from June to September. The whole plant exhales an unpleasant odor.

History.—This is a low undershrub, growing from New England to Virginia, in fields, hedges, rocky places, and along the road-sides. The fruit is round, black, one-celled, containing three irregular-shaped seeds. The bark of the plant is employed in medicine, but that of the root is the most active. It yields its virtues to water.

Action, Medical Uses, and Dosage.—The leaves in warm infusion are sudorific. It has a marked influence upon the secretions, and the circulation. The bark is diuretic and alterative, and has an especial action on the kidneys, increasing secretion and allaying irritation. Very valuable in *dropsy*, *gravel*, and *suppression of urine*, and other urinary disorders. The juice and decoction of the fresh roots are said to be emetic and hydragogue, and have been found efficient in *dropsy*. Dose of decoction (3ss to aqua Oj), 2 to 4 ounces, 3 times a day. Specific *aralia hispida*, 1 to 30 drops.

Specific Indications and Uses.—Diffused anasarca; dropsy of cavities; œdema; dropsy with constipation; renal and hepatic torpor; dyspnoea; and pain in the lumbar region.

ARALIA NUDICAULIS.—FALSE SARSAPARILLA.

The root of the *Aralia nudicaulis*, Linné.

Nat. Ord.—Araliaceæ.

COMMON NAMES: *American*, *Wild*, or *False sarsaparilla*, *Small spikenard*, *Wild licorice*, *Shot bush*.

Botanical Source.—*Aralia nudicaulis* is a smooth, herbaceous, perennial plant, with a large, fleshy, horizontal, creeping, tortuous root, very long, often many feet in length, about 6 lines in diameter, and yellowish or brownish externally; from this arises a solitary, large, compound, radical leaf, the leaflets of which are oval and obovate, acute, and finely serrate. A scape or flower stem also arises from the root, which is shorter than the leaf, naked, about 1 foot high, terminating in three small, simple, many-flowered, globose umbels, without involucre. The flowers are greenish, or greenish-yellow. The fruit is a small drupe or berry.

History.—This plant, sometimes known as *American*, *Wild*, or *False sarsaparilla*, is indigenous, growing in moist woodlands, in the Northern and Middle States, and as far south as Tennessee and South Carolina. The part employed is the root; when fresh it has an agreeable balsamic odor, and a pleasant, spicy, saccharine taste. It yields its virtues to water or alcohol. In commerce this plant is often substituted by spikenard.

Description and Chemical Composition.—The rhizome, when dry, is found in commerce in longitudinally-wrinkled pieces, having but few rootlets, and being a little over 1 foot long, and about $\frac{1}{2}$ inch in diameter, of a grayish-brown color externally, and marked by shallow, cotyloid scape-scars, and annulated on the upper surface. The bark of the root easily exfoliates. Internally the root is white, with a starchy, sponge-like pith, enclosed by a yellowish wood. It breaks with an abrupt fracture, and has a somewhat balsamic odor, and a mawkish, somewhat oily, unpleasant taste. It contains starch, pectin, sugar, resin, and a trace of a volatile oil. For an interesting paper on this drug, see contribution of William Alpers to the American Pharmaceutical Association, 1897.

Action, Medical Uses, and Dosage.—Small spikenard possesses alterative properties, and is used in decoction or syrup as a substitute for sarsaparilla in all cases where an alterative is required. It is likewise used in *pulmonary diseases*. Externally, a decoction of it has been found beneficial as a wash in *zona* (shingles) and in *indolent ulcers*.

ARALIA RACEMOSA.—SPIKENARD.

The root of *Aralia racemosa*, Linné.

Nat. Ord.—Araliaceæ.

COMMON NAMES: *American spikenard*, *Spignet*, *Pettymorrel*.

Botanical Source.—Spignet is an indigenous perennial, having an herbaceous, widely branched, smooth stem, 3 or 4 feet in height, of a dark-green or reddish color, arising from a thick, fleshy, aromatic root. The leaves are compound; the leaf-stalks dividing into three partitions, each of which bears 3 or 5 large, ovate, pointed, serrate, slightly downy leaflets. The umbels are numerous, small, arranged in branching racemes from the axils of leaves or branches, and are composed of small greenish-white flowers, succeeded by dark-purple berries.

History.—This plant grows from Canada to Georgia, and westward throughout the United States. It flowers in July, and is found in rich woodlands, and rocky situations, often growing in the crevices of rocky declivities.

Description and Chemical Composition.—The rhizome is from 4 to 8 inches long, and several inches in thickness, growing obliquely, and having a light-brown color externally, being whitish within. It is prominently marked by scars or cavities, an inch or more in width, where stems of the previous year were attached. The older stem-scars are deepest. The rootlets are long, often attaining a length of 2 or 3 feet, and being about 1 inch in thickness at the base. Their color is like that of the rhizome, the central portion being reddish. They are sparingly branched, and somewhat wrinkled. They break easily, with an irregular, transverse fracture. The taste is pleasantly spicy and balsamic, and the odor of the root peculiar and agreeably aromatic. The whole plant, when bruised, gives off this balsamic aroma. Its constituents are those of the *A. nudicaulis*.

Action, Medical Uses, and Dosage.—The root of *Aralia racemosa* possesses properties similar to that of the *A. nudicaulis*; it was formerly much used in *pulmonary affections*, and enters into the compound syrup of spikenard. Dose: specific *aralia racemosa*, 5 to 30 drops in water, 4 times a day; infusion (3ss to aqua Oj), $\frac{1}{2}$ to 2 fluid ounces.

Specific Indications and Uses.—Atonic states, with cough and irritation of the broncho-pulmonary tract; catarrhal affections.

Related Species.—*Aralia californica*, *California spikenard*. Resembles *A. racemosa* in properties and appearance, though both the root and plant are larger.

ARALIA SPINOSA.—PRICKLY ELDER.

The bark of the *Aralia spinosa*, Linné.

Nat. Ord.—Araliaceæ.

COMMON NAMES: *Prickly elder*, *Angelica tree*, *Hercules' club*, *Toothache bush* or *tree*, *Southern prickly ash* (improperly so-called).

Botanical Source.—The *Aralia spinosa* is a small tree, with an unsymmetric, naked stem, about 10 or 12, sometimes 20, feet high, but taller in warm latitudes,

having prickles below, and the leaves all crowded near the summit. The leaves are very large and long, often 3 to 6 feet in length, prickly, bipinnate, and borne on long, prickly petioles. The leaflets are ovate, acuminate, serrate, sessile, and glaucous beneath. The flowers are white, and disposed in numerous umbels, forming a very large panicle. The involucre is small and few-leaved. The fruit consists of blackish, juicy berries.

History.—The prickly elder inhabits the United States in various parts, from Pennsylvania to Louisiana, and westward to Missouri, growing in damp and rich woods and fields. The thin, ash-colored bark is the part used, although other parts of the plant possess medicinal properties; it has a peculiar, somewhat fragrant odor, and a slightly bitter, biting taste; alcohol or water extracts its properties. It is frequently grown in the Northern States for ornamentation. It blooms in August and September.

Description.—*Aralia* bark, as it occurs in drug houses, is curved, or in thin quilled pieces, with an external gray, smooth surface, or slightly marked with linear elevations, and the stem-bark usually with transverse lines of slender prickles, or in the absence of these, short ridges running crosswise. Beneath the corky layer, the color is brownish-green or green. The inner bark is composed of layers concentrically disposed, and breaks with a smooth, but tough fracture. The taste is sharp, acrid, and bitter; the odor slightly balsamic.

Chemical Composition.—The chemical investigations of this bark by different authors present somewhat conflicting results. L. H. Holden (*Amer. Jour. Pharm.*, 1880) found in it fat, tannin, a slightly acrid resin, and a yellowish glucoside to which he gave the name *araliin*. It is soluble in alcohol and water, and froths considerably in aqueous solution upon shaking. *Araliin*, when acted upon in aqueous solution by hydrochloric acid, splits into sugar and a white, insoluble, tasteless body, called *araliretin* by Holden. Elkins (*Amer. Jour. Pharm.*, 1880) demonstrated the presence of the following organic constituents: starch, glucose, pectin, gum, two acrid resins, a volatile oil, and an alkaloid. The latter constituent, however, J. K. Lilly failed to obtain (*Amer. Jour. Pharm.*, 1882). Lilly isolated the volatile oil by distillation; also the bitter, amorphous, extract-like principle, the resinous, acrid principle, and obtained Holden's *araliin* in pure form, characterized by its striking saponaceous property. Satisfactory tests for tannin were not obtained by Lilly.

Action, Medical Uses, and Dosage.—The fresh bark will produce vomiting and purging; but when dried it is a stimulating alterative, producing a determination toward the surface. The tincture has been used in *syphilitic* and *rheumatic affections*, and in some *diseases of the skin*. The warm infusion, especially when strong, is apt to induce vomiting. The berries in tincture have been found useful in lulling the *pain from a decayed tooth*; also in various *painful affections* of other parts. Much use was made of this bark by physicians in Cincinnati during the *cholera* of 1849-50, in cases where cathartics were required, but where the action of every purgative was difficult to control; the preparation was composed of 1 drachm of compound powder of jalap, 1 drachm of *aralia spinosa*, and 2 drachms of compound powder of rhubarb. Given in powder, in half-teaspoonful doses; or the powder was infused in half a pint of boiling water, of which infusion, when cold, a tablespoonful was given every half hour. In no case in which it was given did it produce a tendency to looseness or choleraic discharges. It is a powerful sialagogue, and is valuable in diseases where the mouth and throat are dry and parched, as a very small portion of the powder will produce a moisture and relieve difficult breathing; also useful in *sore throat*. The dose of tincture (bark 3viiij to dilute alcohol Oj) is from 5 to 60 drops; of the infusion (3ss to aqua Oj) a tablespoonful to a wineglassful.

Related Species.—*Aralia edulis*, Siebold. In Japan it is universally cultivated in fields and gardens, where it attains a height of 3 or 4 feet, flowering in August, and ripening its bluish-black berries in November. It is valued chiefly on account of its root, in Chinese trade called Tang-Kwei, which is eaten like scorzonera, but the young stalks are likewise a delicious vegetable. The root is fleshy, resembling gentian, and has a sweetish, aromatic taste, and an odor approaching that of celery or angelica. It is said to be brought from Western China (Hanbury, *Science Papers*).

Aralia papyrifera, Hooker. (Properly *Fatsia papyrifera*, Decaisne and Planchon.) Native of Formosa. The so-called *Rice paper tree* of the Chinese. The pith of the stem (1 to 1½

inches in diameter) is unrolled by cutting with a sharp knife from circumference to the center, flattened and pressed in small sheets known as *Rice Paper*, and used in ornamental fancy-work, especially to imitate delicate petals in making artificial flowers. For description and illustration see *Am. Jour. Pharm.*, 1879, p. 241.

ARANEA DIADEMA.—DIADEM SPIDER.

The freshly spun web, free from dust, of the *Aranea diadema*, Linné (*Epeira diadema*). Class: Arachnida; Order: Araneidea; Family: Epeiridae.

COMMON NAMES: *Web of diadem spider*, *Papal cross spider*, *Garden spider*, *Cross spider*.

History, Description, and Preparation.—The diadem spider inhabits old walls, stables, etc., throughout America and Europe. It may be known by its large ovoid body, often attaining the size of a small nut. Along the back is a longitudinal line composed of white and yellow points, while three other lines of like appearance traverse the body. This remedy is of homœopathic origin, and followers of that faith prepare a tincture by crushing the live insect and covering it with 5 parts of alcohol. The web only has been employed by Eclectic practitioners. The tincture may be prepared by macerating 2 ounces of the fresh, clean web in 1 pint of 98 per cent alcohol, allowing it to macerate 10 days, then filter.

Action, Medical Uses, and Dosage.—This remedy is but little used by our practitioners. "It has been employed in *ague* and *malarial disease* when there was marked confusion of intellect, with headache and burning of the face and eyes. In *ague* the chill is prolonged, with great pain in the bones, and a feeling as if bruised" (Scudder, *Spec. Med.*, 77). Dose of tincture, prepared as above directed, fraction of a drop to 10 drops (see *Tela Araneæ*).

Specific Indications and Uses.—Chills with confusion of ideas; chills prolonged, with prostration, febrile reaction not high (Scudder, *List of Spec. Ind.*).

ARAROA.—GOA POWDER.

A powder obtained from cavities in the trunk of the *Andira araroba*, Aguiar. Nat. Ord.—Leguminosæ.

COMMON NAMES: *Goa powder*, *Bahia powder*, *Brazil powder*, *Ringworm powder*, *Chrysarobine*, *Chrysarobin* (improperly so-called).

Botanical Source, History, and Description.—This drug must not be confused with *Arariba rubra*, a Brazilian plant, the bark of which was investigated by Rieth, in 1861, and has been used as a red dye for wool in its native country. Dr. Fayer was the first to call attention to Goa powder in the *Med. Times and Gaz.*, Oct., 1875, but was unable to give its origin, farther than that it reached Bombay through Goa on the Malabar coast, thus acquiring the name *Goa powder*, by which it is commonly known. Its source was kept secret for some time, and the powder was sold at exorbitant prices. In the same year (1875) E. M. Holmes called attention to the identity of araroba with goa powder, suggesting that it was probably produced by a species of *Cæsalpinia*, and for some time his conclusion was generally accepted although not without reserve. Dr. J. M. de Aguiar, of Bahia (1879), published an article in pamphlet form upon this subject (*Pharm. Jour. and Trans.*, July, 1879; also *New Remedies*, Sept., 1879) which lightened the mystery that had heretofore surrounded its source. He informs us that *araroba* is derived from a large intertropical tree, the ordinary height of which is 80 or 100 feet. It belongs to the Leguminosæ, and tribe of Dalbergiæ, resembling, in some respects, *Dalbergia miscolobium*, Benth., and *Andira frazifolia*, Benth. After having given a careful botanical description, the author concludes that the tree has been heretofore undescribed, and proposes for it, the name *Andira araroba*, Aguiar, "since the drupaceous fruit, paniced inflorescence, purple flowers, and other characters, clearly point to its being an *Andira*."

The araroba powder is obtained by cutting down the older trees, as they yield it in the greatest abundance, and then scraping the powder from cavities found by splitting the trunk into longitudinal sections. The tree contains an

abundance of resin, by the oxidation of which, Dr. de Aguiar believes, the araroba is produced. When fresh, it is a pale primrose color, but, by age, changes to the color of rhubarb, and, eventually, becomes dark-purple. The tree exists abundantly in all the southern part of the province of Bahia, although the powder now chiefly comes from Camamu and Taperoa. As found in commerce, this agent is in the form of a powder of different degrees of fineness, of a color ranging from light-yellow to dark-chocolate. It resembles the partly decayed matter occasionally observed in cavities of old trees and stumps, and is often mixed with irregular woody fragments. It is now fairly established that it is the partly decayed matter of the *South American* tree above mentioned, and thus, curiously enough, by the way of distant India, where it had been long used, this product of the South American forest was introduced to the medical profession.

Chemical Composition.—Araroba is remarkable for occasionally yielding from 80 to 85 per cent of chrysophanic acid, as shown by Attfield, in 1875, and, according to the same authority, the remainder of the powder examined consists of 7 per cent of a glucoside and bitter matter, 2 of a resinous substance, $5\frac{1}{2}$ of a red woody fiber, and $\frac{1}{2}$ per cent of ash. The ashes consist chiefly of silicate of aluminum, and sulphates of potassium and of sodium. Prof. J. U. Lloyd examined several specimens upon the market, and, in all cases, obtained a much smaller proportion of chrysophanic acid than stated by Mr. Attfield. Therefore, he concluded that Attfield must have procured an unexceptionally rich specimen of araroba, or that which reached this country was very inferior. Araroba readily yields chrysophanic acid to benzin. When heated in a suitable vessel, a sublimate is obtained, which, doubtless, consists largely of the aforementioned acid, as it is colored red by alkalis in solution. Araroba is chiefly employed for the preparation of chrysophanic acid (which see). Liebermann and Siedler, are authority for the statement that chrysophanic acid does not exist ready-formed in araroba, but is formed by oxidation of a natural constituent, to which they give the formula $C_{20}H_{12}O_7$, and the name *Chrysarobin* (previously applied to araroba).

Action, Medical Uses, and Dosage.—In the Indies this agent has been employed for the removal of *taenia solium*, and in the treatment of certain *cutaneous maladies*. Attfield, Fayrer, Da Silva Lima, Squire, Hebra, Bernier, Blanc, Thin, and many other medical men have successfully employed this powder in the treatment of *herpes circinatus*, *porrigo scutulata*, *porrigo decalvans*, *syccosis*, *favus*, *psoriasis*, *eczema*, *lichen*, *acne*, and other diseases of the skin. The powder is mixed with vinegar or lemon juice to form a thin, pasty mass, or is well incorporated with glycerin or starch paste, and then applied over the eruption once or twice a day, for from 5 to 8 days successively, in which period of time the cure is generally affected. Its application causes, after some length of time, a temporary uneasy sensation in the part to which it is applied, the eruption assumes a whitish appearance, and the surrounding tegument presents the appearance as of a dark stain; as the cure progresses, the skin assumes its normal color. For internal use, it may be taken in the form of pills, made by incorporating it with medicinal soap. For external application, it may be used as above stated, by means of a small brush, or a tincture of the powder may be painted upon the affected parts. It may be also used in the form of an ointment, consisting of from 15 to 60 grains of the powder, from 15 to 30 drops of acetic acid, all thoroughly mixed with an ounce of benzoinated lard. At the present time, however, chrysophanic acid and chiefly chrysarobin (which see) are used in preference to the goa powder.

ARCHANGELICA ATROPURPUREA.—PURPLE ANGELICA.

The root, herb, and seed of the *Archangelica atropurpurea*, Hoffman (*Angelica atropurpurea*, Linné, *Angelica triquinata*, Michaux).

Nat. Ord.—Umbelliferae.

COMMON NAMES: *Purple angelica*, *Masterwort*, *High angelica*, *Great angelica*.

Botanical Source.—The *Angelica atropurpurea* has a root of a purple color, and a smooth, dark-purple, furrowed, hollow, glaucous stem, 5 or 6 feet high, and 1 or 2 inches in diameter. The leaves are ternately divided and the large petioles

much inflated, channeled on the upper side; the leaflets are pinnate, 5 to 7 in number, sharply cut-serrate, acute, pale beneath, the terminal one sometimes 3-lobed, the lateral one of the upper division decurrent. The pale, greenish-white flowers are borne in three large, terminal, many-rayed, spreading, spherical umbels, 6 to 8 inches in diameter, without the involucre. The umbellets are dense, sub-hemispheric, on angular stalks, and with involucels of subulate bracts longer than the rays. The calyx 5-toothed; the petals equal, entire, with the point inflexed. The involucels are short, about 8-leaved. The fruit is smooth, compressed, elliptic, somewhat solid and corticate.

Description.—The root is about $\frac{1}{2}$ inch in diameter, and 3 to 6 inches in length. It is branched, of a pale, brownish-gray color on the external surface, which is deeply furrowed. Internally it is nearly white. It breaks with a short fracture, showing a thick bark finely dotted with resinous deposits, enclosing a soft wood. It has a fragrant odor, and is spicy and sweet to the taste, afterward bitter. It is extremely liable to the attack of insects.

History and Chemical Composition.—This perennial plant grows in fields and damp places, developing greenish-white flowers from May to August. The plant has a powerful, peculiar and not disagreeable odor, and a sweet taste, succeeded by considerable pungency and spiciness; much of these properties is lost by dessication. They are due to a volatile oil, acrid soft resin, and a volatile acid. Starch also abounds in the root. The fresh root is reputed to act as a poison.

Action, Medical Uses, and Dosage.—Aromatic, stimulant, carminative, diaphoretic, expectorant, diuretic, and emmenagogue. Used in *flatulent colic* and *heart-burn*, and *nervous headache*. The root has been candied and eaten. It is said to promote the menstrual discharge. In *diseases of the urinary organs, calculi* and *passive dropsy*, it is used as a diuretic, in decoction with *uva ursi* and *Eupatorium purpureum*. Dose of the powder, 30 to 60 grains; of the decoction, 2 to 4 ounces, 3 or 4 times a day. The *Archangelica officinalis*, Hoffmann (*Angelica Archangelica*, Linné), may be substituted for the above.

Related Species.—*Archangelica hirsuta*, Torrey and Gray (*Angelica hirsuta*, Michaux). U. S. (Southern States). Often collected with purple angelica, the root of which it resembles.

ARCHANGELICA OFFICINALIS.—GARDEN ANGELICA.

The root and seeds of the *Archangelica officinalis*, Hoffmann (*Angelica Archangelica*, Linné, *Angelica officinalis*, Moench).

COMMON NAME: Garden angelica.

Botanical Source.—Garden angelica is a plant about 5 or 6 feet high. Its biennial root is fleshy, quite thick and long, and from it ascends every year a smooth, branched, fistulous, articulated and furrowed stem, of a purple color. The leaves are large, bipinnate, with acute, lance-ovate, serrate leaflets, the terminal one trilobate, and are borne on hollow foot-stalks. The greenish-white flowers are arranged in umbels which in turn are made up of compact, semiglobular umbellets.

History.—This plant is a native of Northern Europe, but is also found further south, especially in high altitudes, as among the Alps and Pyrenees. Much of it is cultivated in Germany from whence the drug market is chiefly supplied. The cultivated variety is said to differ from the native species sufficiently for some botanists to classify it as a distinct species. Thus it has been known as *Archangelica sativa*, Fries (*Angelica sativa*, Miller). The root should be gathered in the first year's autumn, as it is more likely to keep without becoming covered with mould. Its properties are in part abstracted by water, and fully by alcohol. It is highly valued as a domestic drug and condiment by the natives of Lapland where it is indigenous. The stems are preserved in Europe and employed as a food and gastric excitant. The fresh root when broken, emits an aromatic fluid having the appearance of honey. The warm infusion is an eligible form of administration.

Description.—**Root.** The root-stock is from 2 to 4 inches in length, and seldom exceeds 2 inches in thickness. It is fusiform, corrugated, annulated above, and tipped with the remains of leaf-stalks. It has many tuberculated

rugose branches which are from 5 to 12 inches long, and $\frac{1}{2}$ inch thick. The color externally is gray-brown, and it is whitish or yellowish-white within. It has a thick bark enclosing a yellowish wood. The bark shows resin dots, indicating the position of resin ducts. The root breaks with an amylaceous fracture. Its taste is sweetish, spicy, and followed by bitterness. It has an aromatic fragrance, and is liable to attack and destruction by insects.

SEEDS.—The seeds are of an ashen color, oval, from 2 to 3 lines in length, slightly bifid at the extremities, convex with three distinct ridges on one surface, and traversed on the other by a single groove running lengthwise. Their odor is aromatic, and their taste pungent, sweetish, and bitter.

Chemical Composition.—This root contains the usual plant constituents as, albumen, lignin, tannin, pectin, starch, sugar, and salts; also malic acid (Buchner). Buchner, in 1842, obtained from the root *angelic acid* ($C_8H_8O_2$), an unsaturated volatile body, of acid taste and aromatic smell. It crystallizes in colorless prisms, fusing at $45^\circ C.$ ($113^\circ F.$). Buchner also abstracted a wax-like, white substance, crystallizing from alcohol in warty masses; an acid resin of acrid taste, capable of forming acicular crystals from alcoholic solution. To this substance he gave the name *angelicin*. In 1877, Brimmer proved its identity with Husemann's *carotin*, and still later, 1886, Arnaud demonstrated that in all probability it is identical with *phytosterin*, a cholesterin-like body contained in *Physostigma venenosum* (calabar bean). Buchner finally obtained from the root an amorphous, bitter principle, and a yellow, volatile oil which was subsequently investigated quite extensively. It consists, for the most part, of terpenes ($C_{10}H_{16}$) (Beilstein and Wiegand, 1882), containing, among other constituents, dextrogyrate *phellandrene* (Schimmel's Reports, 1891-93-96). There are also oxygen compounds present in the oil. In 1880, R. Müller isolated therefrom *oxymyristic acid* ($C_{14}H_{26}O_4$). The presence of methyl-ethyl-acetic acid, an isomer of valeric acid, has also been established. In 1896, Schimmel & Co. state that the oil from the seed is abundant, and deserves the preference over that distilled from the root. The percentage of oil from the dried root is 0.35 to 1 per cent; from the fresh root 0.25 to 0.35 per cent. The specific gravity at $15^\circ C.$ ($59^\circ F.$) is 0.855 to 0.905 (Schimmel & Co., *Semi-Annual Reports*, Oct., 1893).

Action, Medical Uses, and Dosage.—Diuretic, stimulant, tonic, and emetic. It has been applied as a fomentation in *tumefactions* and *swellings*, and given internally in *enteric fever* and other *typhoid states*, *chronic rheumatic complaints*, *gout*, and *malarial intermittents*. As a stimulant to the respiratory mucous surfaces it has been serviceable in *chronic bronchitis*. The dose of the infusion (3j to aqua Oj) is from $\frac{1}{2}$ to 1 wineglassful; of the powdered root, 5 to 30 grains; of the powdered seeds, 5 to 30 grains.

Related Species and Preparations.—*Levisticum officinale*, Koch (*Ligusticum Levisticum*, Linné). *Nat. Ord.*—Umbelliferae. *Lovage*. Mountains of South Europe and in gardens. The root and seeds are employed. The former is from 1 to $1\frac{1}{2}$ inches thick, has several heads, is somewhat annulated, and is wrinkled lengthwise. Externally, yellow-brown; internally, light-yellowish. The thick bark is radially striated, fissured externally, and has numerous resin cells of an orange color, arranged in imperfect circles. Its odor is aromatic, resembling somewhat that of angelica. Its taste is pungent, mucilaginous, and balsamic. The seeds are ovate-oblong, or elliptical, small, compressed, curved, and strongly marked with ribs, which are winged, and in the grooves between the ribs occur one or more oil-tubes. The color of the fruit is yellowish-brown. Analysis has revealed several hard and soft resins, one of which has a pungent, bitter taste, a thick, volatile oil, containing a large amount of stearopten, sugar, and mucilage. The coloring principle is *ligulin* (Nickles) and has been proposed as a test for calcium compounds in water, the substance imparting to distilled water a permanent crimson hue, which with lime-water changes in a brief space of time to a handsome blue. Lovage is a gastric stimulant, diuretic, emmenagogue, and carminative. It closely resembles angelica in its action and uses. The infusion is the best form of administration.

Ligusticum sibiricum, Watson. *Osha*, or *Colorado cough root*. Rocky Mountain regions. Root resembles the preceding in appearance and action. Used as a stimulating expectorant (see A. J. P., 1890-91). A Mexican umbellifer, of unknown botanical source, known as *Osha* root, yielded *oshaic acid*, which very closely resembles angelic acid (Haupt).

Ligusticum actaeifolium.—Southern States. Properties same as Lovage.

Ligusticum sinense.—The *Kao-pén* of the Chinese, who employ it medicinally.

Laserpitium latifolium, Linné. This is the *Radix gentianae albae* of former times, so called on account of its gentian-like appearance. It has, however, a white interior, and a brownish-white exterior. Its bark is thick and spongy, and is interspersed with resin cells of a yellow color. It contains a crystalline bitter, *lasipitin* ($C_{15}H_{22}O_4$). It is reputed a prompt purgative.

Pimpinella Saxifraga, Linné. *Small burnet saxifrage*.—A European perennial umbellifer, the root of which has a pungent, biting, balsamic, sweetish and bitterish taste, and a disagreeable, strongly aromatic odor. Acrid resin, a bitter principle, *pimpinellin*, soluble in alcohol, and a golden-yellow, light, volatile oil, having a sharp taste, and a parsley-like odor, are its chief constituents. The root is reputed diuretic, diaphoretic, and stomachic. Its uses are similar to those of *levisiticum* and *angelica*. *Asthma*, *catarrh*, *dropsies*, *amenorrhœa*, etc., and *toothache* (applied locally) have been treated with it. It was formerly much used (in Germany) to expel mercury from the system after a mercurial course. The following tincture may be employed:

TINCTURA PIMPINELLÆ (N. F.), *Tincture of Pimpinella*. *Formulary number*, 420.—“*Pimpinella*, root, one hundred and sixty-five grammes (165 Gm.) [5 ozs. av., 359 gra.]; alcohol, water, of each a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 Ml.]. Mix 2 volumes of alcohol with 1 volume of water. Macerate the *pimpinella*, reduced to a moderately coarse (No. 40) powder, with enough of the menstruum to keep it distinctly damp during 12 hours. Then percolate it with the same menstruum, in the usual manner, until 1000 Cc. [33 fl. 3, 391 Ml.] of tincture are obtained.

Note.—This preparation is approximately of the same strength as that which is official in the *Germ. Pharm.* *Pimpinella* root is derived from *Pimpinella Saxifraga*, Linné, and *Pimpinella magna*, Linné—(*Nat. Form.*).

Pimpinella magna, Linné, is also known as *Small burnet saxifrage*, and is similar to the foregoing in properties and used like it. It enters into the foregoing tincture.

ARECA.—BETEL NUT.

The seed of *Areca Catechu*, Linné.

Nat. Ord.—*Palmae*.

COMMON NAMES: *Areca nut*, *Betel nut*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 276.

Botanical Source, History, and Description.—The tree furnishing *areca* nut (*Semen arecæ*) is a handsome palm, probably indigenous to the Malayan group of islands where it is cultivated. It is also cultivated in Ceylon, India, Indo-China, and the Philippine Islands. Its straight trunk, nearly 2 feet in circumference, shoots upward to a height of 40 or 50 feet. The flowers are borne on a spadix, the male flowers above, the female flowers lowermost. The fruit is ovoid and smooth. It is about as large as a small-sized hen's egg, orange-yellow in color, and consists of a fibrous envelope adherent to a crustaceous endocarp enclosing the single seed. The seeds are hard and heavy, and are cut with difficulty. In shape they are round-conical, and depressed at the base, and at one side of the depressed portion a tuft of fibres is frequently found, showing where the seed was attached to the pericarp. Their color externally is brown, mottled with fawn color, giving it a reticulated appearance. Its internal structure closely resembles that of the common nutmeg, being a brown-red with whitish veins. The odor, when the nut is fresh, is feeble, resembling cheese. The taste is astringent and sub-acrid. Betel nuts have long been employed by the Asiatics as a masticatory, for sweetening the breath and hardening the gums, and are believed by them to improve the digestive powers. They have been given to both dogs and human beings in China and India as a vermifuge (*Pharmacographia*). They are often chewed with slaked lime and *piper betle* leaves (see *Matico, Related Species*).

Chemical Composition.—*Areca* nuts contain tannin, gallic acid, gum, lignin, volatile and fixed oils, iron peroxide, magnesium phosphate, and other salts. The tannin resembles catechu-tannic acid, is red, and strikes green with ferric salts, quickly changing to brown, and when an alkali is added, a violet coloration ensues. It is not very soluble in either hot or cold water. Pyrocatechin was obtained from it by dry distillation, but no catechin is present in the nut (*Pharmacographia*). Four alkaloids were isolated by Jahns (*Amer. Jour. Pharm.*, 1889, 1891) from *areca* nuts. *Arecoline* ($C_8H_{13}NO_2$), a colorless, volatile, and oily, nicotine-like principle, identical with Bombalon's (1885) *arekane*. The tæniifuge properties of the drug are probably due to this principle. It mixes with water, chloroform, alcohol and ether. It yields crystallizable salts, among which the hydrobromide crystallizes best; some of these salts are deliquescent. *Arecaïne* ($C_7H_{11}NO_2 + H_2O$) probably a betaine-like body, physiologically inert, forms permanent, colorless crystals, insoluble in ether, chloroform, and benzol, almost insoluble in absolute alcohol, but dissolving with ease in diluted alcohol and

water. Its salts are crystallizable, acid, and freely dissolve in water. A third alkaloid, *arecaidine* ($C_7H_{11}NO_2 + H_2O$), an isomer of *arecaine*, and non-poisonous, was discovered by Jahns, in 1891. The poisonous *arecoline* aforementioned is methyl-*arecaidine*. A fourth alkaloid, discovered by Jahns, and called *guvacine* ($C_8H_9NO_2$), is the lower homologue of *arecaidine*, and non-poisonous.

Action, Medical Uses, and Dosage.—Astringent and tænicide. The chief use of this drug is to expel *tapeworms*, for which it is said to be efficient in doses of 2 to 6 drachms of the powdered nut, administered in syrup. The smaller dose is generally effectual. A hard charcoal suitable for dentifrices is prepared from the nut. *Arecoline* is the tænifuge principle, resembling *pelletierine*, both chemically and in action. *Arecaine*, the betaine-like body, has been likened to *trigonelline* from *fenugreek*. Experimentation with it upon animals proved it to be inert.

ARGEMONE.—PRICKLY POPPY.

The plant *Argemone mexicana*, Linné.

Nat. Ord.—Papaveraceæ.

COMMON NAME: *Prickly poppy*.

Botanical Source.—This annual plant has a stem about 2 feet high, erect, bristly, and glaucous. The leaves are sessile, alternate, sinuately lobed, the angles armed with prickly spines, and spotted with white patches. The flowers, which are either yellow or white, and about $1\frac{1}{2}$ inches wide, are solitary, have numerous stamens and from 4 to 6 petals. The sepals, 3 in number, are deciduous and prickly. The stigmas, 4 to 6, are reflected. The capsule is ovate, prickly, about 1 inch in diameter, terminated by a radiate, subsessile stigma, and has many seeds which are minutely pitted, and blackish in color. The plant, when bruised, exudes a viscid, milk-like juice, which turns yellow when exposed to the atmosphere. The whole plant has an acrid, bitter taste.

History and Chemical Composition.—This plant is native to Mexico, the West Indies, Southern and Western United States, and has been naturalized in Brazil, Hindustan, Africa, and other subtropical and tropical places. The seeds of this plant yield a large quantity of a pale-yellow, fixed oil, of the drying variety, yet slow to dry, doing so incompletely, has a sickening odor, and is nearly bland, or but feebly acrid, and not disagreeable to the taste. This oil yielded a hard soap with soda, and gave in the soap-liquor acetic, valerianic, and butyric acids, and a trace of benzoic acid (Frölich, 1871). The oil is a mild cathartic in small doses, and has a density of 0.919 at $16.5^{\circ} C.$ ($61.8^{\circ} F.$) (Flückiger). From the capsules and leaves a small quantity of *morphine* was obtained by Charbonnier, in 1868. It is also believed to contain *sanguinarine*. The oil has been proposed for use in painting. The flowers have soporific properties (De Candolle).

Action, Medical Uses, and Dosage.—Emetic, purgative, anodyne, and narcotic. The juice is applied in the East to *warts*, *chancres*, *ulcers*, *corneal opacities*, and *ophthalmia*; internally, it is used in certain *skin diseases*. The juice in its acrimonious qualities resembles gamboge. The oil is useful in *flatulent colic*, with atony of the bowels and constipation; also in *headache*. From 10 to 20 drops of the oil mildly purges; larger doses act as an emetic and hydragogue cathartic. The herb in infusion is diaphoretic. It is not much used in this country.

ARGENTI CYANIDUM (U. S. P.)—SILVER CYANIDE.

FORMULA: $AgCN$. MOLECULAR WEIGHT: 133.64.

SYNONYM: *Argentum cyanatum*.

Preparation.—This salt may be prepared by adding an excess of pure potassium cyanide, in solution, or of hydrocyanic acid, to a solution of silver nitrate. Collect the precipitate, wash it well and dry it. The U. S. P. of 1870 directed its preparation as follows: Dissolve silver nitrate, 2 troy ounces, in distilled water, 1 pint, and pour it into a glass receiver (tubulated). Dissolve potassium ferrocyanide, 2 troy ounces, in distilled water, 10 fluid ounces; put into a tubulated

retort, which has been first connected with the above-mentioned glass-receiver, then mix with distilled water, 4 fluid ounces, sulphuric acid, $1\frac{1}{2}$ troy ounces, and pour the mixture into the solution of potassium ferrocyanide, and with moderate heat distill on a sand-bath 6 fluid ounces, or until a precipitate is no longer thrown down in the receiver. Wash the precipitate, and dry the salt.

Description.—"A white powder, without odor or taste, permanent in dry air, but gradually turning brown on exposure to light. Insoluble in water, alcohol, or cold nitric acid, but soluble in boiling nitric acid with evolution of hydrocyanic acid; also soluble in ammonia water and in solution of sodium hyposulphite, or of potassium cyanide. When heated the salt fuses, gives off cyanogen gas, and on ignition leaves a residue of metallic silver, amounting to 80.56 per cent of its original weight"—(U. S. P.). Chlorine water and heated solutions of iodides and chlorides decompose this salt, hydrocyanic acid being evolved. Silver chloride and hydrocyanic acid are produced by the action of diluted hydrochloric acid on this salt. Solution of potassium cyanide is the best solvent for silver cyanide, a double cyanide being formed. "Silver cyanide should be kept in dark amber-colored vials, protected from light"—(U. S. P.).

Use.—It is used chiefly in preparing extemporaneously diluted hydrocyanic acid.

ARGENTI IODIDUM (U. S. P.)—SILVER IODIDE.

FORMULA: AgI. **MOLECULAR WEIGHT:** 234.19.

SYNONYM: *Argentum iodatum.*

Preparation.—Dissolve separately equal parts of pure potassium iodide and pure silver nitrate in about 12 parts of water, and pour gradually into the potassium iodide solution the solution of silver nitrate, stirring the mixture constantly. Filter and wash the precipitate thoroughly with distilled water, and dry the product upon unsized paper. According to H. Vogel a slight excess of the potassium iodide insures greater stability of the salt when exposed to light. "Silver iodide should be kept in dark amber-colored vials, protected from light"—(U. S. P.).

Description and Tests.—The Pharmacopœia describes silver iodide as "a heavy, amorphous, light-yellowish powder, unaltered by light, if pure, but generally becoming somewhat greenish-yellow, and having neither odor nor taste. Insoluble in water, alcohol, diluted acids, or in solution of ammonium carbonate, but soluble in about 2500 parts of stronger ammonia water. It is also dissolved by an aqueous solution of potassium cyanide and by a concentrated solution of potassium iodide, and the resulting solutions yield a black precipitate with hydrogen sulphide T.S. or ammonium sulphide T.S. When heated to about 400° C. (752° F.), the salt melts to a dark red liquid, which, on cooling, congeals to a soft, yellow, slightly transparent mass. When mixed with ammonia water it turns white, but regains its yellowish color upon being washed with water. If a small quantity of chlorine water be agitated with an excess of the salt, the filtrate acquires a dark blue color on the addition of starch T.S. If 0.5 Gm. of the salt be digested for five minutes with 10 Cc. of a cold 15 per cent solution of ammonium carbonate, the filtrate, when supersaturated with nitric acid, should not be rendered more than faintly opalescent (absence of chloride). On digesting a portion of the salt—which has been found to be free from chloride, or from which the latter has been completely removed by repeated digestion with ammonium carbonate—for five minutes with 10 Cc. of ammonia water, and supersaturating the filtrate with nitric acid, only a slight opalescence, but no yellowish-white precipitate, should be produced (absence of bromide)"—(U. S. P.). This salt sublimes at a white heat. When strongly heated on charcoal with a blow-pipe flame it ignites, producing a green blaze and giving off a white smoke, leaving a small residue of metallic silver. When this salt is fused it assumes yellow, red, and deep-brown hues, according to the degree of heat employed. Water reprecipitates it from its potassium iodide solution.

Action, Medical Uses, and Dosage.—A practically obsolete medicine, formerly given in $\frac{1}{2}$ grain to 2 grain doses in *whooping-cough, asthma, chorea, visceral*

neuralgia, and *sypilis*. Dr. Charles Patterson, of Dublin, found it to act in various diseases as a substitute for nitrate of silver, producing its therapeutical influences without discoloring the skin. The dose for an adult is 1 or 2 grains, in pill, every 3 or 4 hours.

ARGENTI NITRAS (U. S. P.)—SILVER NITRATE.

FORMULA: AgNO_3 . MOLECULAR WEIGHT: 169.55.

Preparation.—"Two parts of pure silver in small pieces are to be dissolved in 3 parts of pure nitric acid, specific gravity 1.41, diluted with $1\frac{1}{2}$ parts of distilled water, at a gentle sand-bath heat, and the clear solution—after decanting and filtering the last portions, if necessary—evaporated in a porcelain dish, at first over an open fire, and afterward, when it has become thick, under constant stirring with a glass rod, to perfect dryness in a sand-bath. On account of the nitrous vapors that are evolved this process should be performed under a chimney with a good draught. If the crystallized salt is required, the dried mass is again dissolved in its weight of distilled water, and allowed slowly to evaporate in a sand-bath to about half; it is then placed for some days in a cool spot, the mother liquors poured from the separated crystals, and again slowly evaporated. The crystals are not dried on paper, but drained in the vessel in which they formed, dried and kept in a bottle excluded from the light. When required in sticks a portion is fused over a spirit lamp, in a porcelain dish, being constantly stirred with a glass rod, and the liquid mass poured into a bright iron mold that has been previously warmed. The sticks as soon as cold are removed, and the tubes wiped with dry filtering paper, to remove any adhering salt. Eight parts of pure silver yield 12 parts of nitrate" (Witt.). The reaction involved in this process is as follows: $\text{Ag}_8 + 4\text{HNO}_3 = 3\text{AgNO}_3 + \text{NO} + 2\text{H}_2\text{O}$. $\text{NO} + \text{O} = \text{NO}_2$.

All organic matter must, from this as well as all other silver salts, be carefully excluded, as they facilitate their reduction and discoloration, consequently the crystals must not be dried on filtering paper. It is sometimes recommended to rub the surface of the mold with oil, but this is unnecessary and inadvisable, as the sticks slide equally well out of the dry and polished cylinders, and the oil will cause a gray appearance on their outer surface. The salt must be poured into the mold as soon as it is liquefied, because it soon begins to evolve nitric acid, and the oxide formed becomes reduced to a gray metallic covering which is prejudicial to the appearance of the preparation. If such a pellicle has formed (it will mostly remain in the dish after pouring out the fluid portion) a few drops of pure nitric acid must be added to the next portion of the salt, previous to fusing it. The salt must not be fused in an iron vessel.

Description.—"Colorless, transparent, tabular, rhombic crystals, becoming gray or grayish-black on exposure to light in presence of organic matter; without odor, but having a bitter, caustic, and strongly metallic taste. Soluble at 15°C . (59°F .) in 0.6 part of water and in 26 parts of alcohol; in 0.1 part of boiling water, and in 5 parts of boiling alcohol. When heated to about 200°C . (392°F .) the salt melts, forming a faintly yellow liquid, which, on cooling, congeals to a pure white, crystalline mass. At a higher temperature it is gradually decomposed with evolution of nitrous vapors"—(U. S. P.). The presence of hydrogen sulphide will also cause the crystals of silver nitrate to turn black. The sticks or rods of the salt are at first white, but from the action of light and organic matter become grayish, and when broken they present a crystalline texture with a radiated surface. They differ from the crystallized nitrate only in form and color, and do not contain any water of crystallization, as has been supposed. Nitrate of silver, especially in solution, should always be kept in dark, amber-colored bottles with glass stoppers, as cork quickly decomposes it. It is a heavy, non-deliquescent, anhydrous salt, and is incompatible with all waters containing salt, phosphorus, charcoal, vegetable astringent solutions, chlorides, most acids and their salts, earths, and alkaline solutions. Its specific gravity is 3.521. It corrodes the soft tissues, and in contact with the hair, skin, nails, linen, and almost all organic substances, it produces stains of an indelible black—(Ed.). Stains of nitrate of silver may be removed by first applying a strong solution of

iodide of potassium, and afterward a solution of hyposulphite of sodium; or a solution of cyanide of potassium will remove them; or the application of tincture of iodine, and afterward liquor potassæ, or solution of sodium hyposulphite.

Tests.—Fused nitrate of silver almost always contains a small proportion of free silver when in sticks, which may be known by the undissolved black powder present in its solution in distilled water. Precipitate a solution of nitrate of silver by an excess of chloride of sodium; if this precipitate is entirely soluble in ammonia the salt is pure; if not, lead is present. Hydrogen sulphide gas passed through the liquid, after having removed the above precipitate, gives a white precipitate if zinc be present, and black if there be any copper. Nitrate of potassium may be suspected when a colorless fracture is presented upon breaking the sticks, and when the salt is entirely soluble without the black powder sediment. It is readily distinguished by precipitating all the silver as chloride by means of hydrochloric acid, and evaporating to dryness, when the nitrate of potassium will be found in the residue. "An aqueous solution of the salt is neutral to litmus paper, and yields, with hydrochloric acid, a white precipitate, which is readily dissolved without color (absence of copper) by ammonia water. If 5 Cc. of a 10-per-cent aqueous solution of the salt be mixed with 20 Cc. of diluted sulphuric acid, and heated to boiling, no turbidity should be perceptible (absence of lead). If another portion of the aqueous solution be completely precipitated by hydrochloric acid, and the filtrate evaporated to dryness, no residue should be left (absence of foreign salts). 0.34 (0.3391) Gm. of silver nitrate dissolved in 10 Cc. of water should require, for complete precipitation, 20 Cc. of decinormal sodium chloride V.S. (corresponding to 100 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Applied to the tissues silver nitrate coagulates the albumen and fibrin of the parts, forming a white pellicle, which may become dark and quickly dries. Intense smarting or burning pain attends its application. Ulceration and sloughing may supervene from its use as a caustic, but the mitigated stick and the solutions are quite superficial in action. It stains the tissues dark or black, which stains may be permanent if often repeated. When swallowed, pain, heat, and vomiting, and other distress indicative of an irritant poison are experienced. There may be a feeble pulse, cold, clammy perspiration, anæsthesia, unconsciousness, loss of muscular power, and convulsions. Paralysis of central origin may result from its use. The only symptom from its long-continued use internally in small doses is a peculiar dark line upon the gums and conjunctiva, followed by a discoloration of the skin of a dingy or slate color. This condition, known as *argyria*, is permanent, and is produced by the deposit of silver in metallic form in the pigmentary portion of the skin.

Some practitioners consider this salt a tonic and nerve-stimulant, allaying irritability of the nerve centers, and improving nutrition, and employ it to fulfil these indications in *epilepsy*, *chorea*, *angina pectoris*, etc., as well as administering it in *intestinal ulceration* during *typhoid fever*, *diarrhœa*, etc. It has largely lost favor in these complaints, though it is recommended by some as an internal agent in *perforating gastric ulcer*, *gastric catarrh*, *flatulent dyspepsia*, and *gastralgia*. Also in ulcerative or non-ulcerative *chronic diarrhœa*, *dysentery*, with pinkish blood-streaked mucoid discharges, and in *cholera infantum* to allay chronic irritation and assist the recuperative powers of the membranes when feeble. The dose for this purpose should be very small, from $\frac{1}{16}$ to $\frac{1}{8}$ grain; some recommend from $\frac{1}{8}$ to $\frac{1}{2}$ grain. We believe we possess better remedies for these disorders. However, it is seldom used as an internal agent, but externally as an escharotic, either in the solid form, or dissolved in distilled water. It has been beneficially applied to *sluggish ulcers*, *warts*, and other growths, *fungous flesh*, *chancres*, and in *ulcers of the cornea*, some forms of *ophthalmia*, *granulation of the lids*, *fetid discharges from the ear*, *aphthous affections of mouth*, and *spongy gums*. It has likewise been recommended as a topical remedy in *erysipelas* and various other *external inflammations*, *leucorrhœa*, *gonorrhœa*, *uterine ulcerations*, *granulations* and *excoriations*, and *stricture of the urethra* (care should be had in its use in the urethra); also in *ringworm*, and some other forms of *chronic cutaneous diseases*. A solution of it is highly recommended in *chronic laryngitis*, *pharyngitis*, *pertussis*, *asthma*, and *venereal ulceration of the throat*, applied by means of a sponge fastened to one end of a piece of whalebone. It has more recently been used in the form of spray in

tracheal, laryngeal, nasal, and faucial diseases—1 to 10 grains of the salt to 1 fluid-ounce of distilled water, and sprayed upon the affected parts every day or two, or even oftener. A caustic solution should not be passed into the lungs or bronchi. The solid stick is sometimes used in *ulcerations of the throat* and *chilblains*. A modified nitrate of silver is much used in *trachoma* and other affections of the eye. In eye disorders the greater the inflammation the stronger should be the application, and as the severity of the symptoms decline the strength of the application should be reduced. In *catarrhal trachoma* a 25 per cent solution or the mitigated stick may be used. In *corneal ulcer* a 5 per cent solution may be applied after curetting the lesions. In such ulcers, however, care should be had that no deposit of silver should take place and thereby obscure vision. Solutions of silver nitrate should not be dropped into the ear, but if to be applied should be carried upon cotton, or fused to a fine wire. *Perforation of the drum* refusing to heal after *suppurative otitis media* should be treated with the agent upon a wire, simply touching the margin of the perforation. Closure follows. *Non-confluent exuberant granulations* and *redundant tissues*, after operations, should be treated with it, either in solution or by stick. In *gonorrhœal ophthalmia* and *ophthalmia neonatorum*: R Silver nitrate, grs. v to x; aqua dest., flʒi. Mix. Wash the eye well with warm water and apply (Locke). It is well to have salt water at hand to limit its action if desired.

Gonorrhœa of the female is amenable to it, and for *leucorrhœa* dependent upon irritation and subacute inflammation: R Silver nitrate, grs. iii to iv; aqua dest., flʒi. Mix. Apply with a swab or syringe (Locke). In *gonorrhœa* of the male silver nitrate in solution sometimes cures, but more often aggravates the disease. Painting the scrotum with a solution is said to sometimes abort *epididymitis*. *Felons* are occasionally aborted in the same manner. In *erysipelas* it is inferior to tincture of chloride of iron.

In using silver nitrate if the pain be excessive from the application it may be at once relieved by washing the parts with a solution of common salt, which decomposes it, and converts it into the insoluble chloride of silver. The same article is an antidote to its poisonous effects when taken internally in too large doses. In obstinate or severe *dysentery*, after having first cleansed the rectum by an injection of soap and warm water, another injection, composed of nitrate of silver 10 grains, distilled water 1 fluid ounce, may be given, and repeated in an hour if necessary. The second or third injection is said to cure. For a child less than a year old, 1 grain of the nitrate to the fluid ounce of water, and so in proportion (W. H. Parsons, *College Journal*, Cincinnati, Ohio, III, 269). Its use in this manner has been practically abandoned, though it may be resorted to in extreme cases. The dark color of the skin produced by the internal use of nitrate of silver generally remains for life. A premonitory indication of this discoloration is the appearance of a dark-blue line along the margins of the gums, darker than that caused by the internal use of lead. Duncan states that it is said to be at last removed by a steady course of cream of tartar; and Pereira suggests to wash the body with diluted nitric acid daily, at the same time administering it internally. Others advise the use of iodide of potassium during the period of taking the silver salt. For the purpose of operating with greater safety in cavities where the fracture of the caustic might be dangerous, Chaisaignac employed nitrate of silver fused round a platinum wire; thus applied it adheres firmly to the wire, even when cracked; or aluminum wire might be substituted for the platinum.

The dose of the crystals of nitrate of silver is from $\frac{1}{4}$ to $\frac{1}{2}$ of a grain, repeated 3 times a day, and gradually increased to 2 or 3 grains. It may be given in pill form with bread-crumbs, or in solution largely diluted, but preferably in pill with some vegetable extract. When employed locally in solution its strength is varied, according to the condition of the parts to be acted upon and the character of the affection—from 5 to 80 grains to the fluid ounce of water.

Specific Indications and Uses.—Intense tormina and tenesmus, with discharge of pinkish, blood-streaked mucus in dysentery, or pinkish, blood-streaked discharges in diarrhœa, with flatulence, mucorrhœa, and cardiac palpitation.

Indelible Ink.—Indelible ink for marking linen, etc., owes its character to this salt. "An ink for marking linen has been largely used, which does not require a mordant, flows freely from the pen, does not require a strong or long-continued heat to develop the black mark, and which will not destroy the texture of the finest cambric. It is prepared

thus: Dissolve nitrate of silver, 1 ounce, in a sufficient quantity of distilled water; also dissolve crystallized carbonate of sodium, 1½ ounce, in sufficient distilled water. Mix the two solutions; a precipitate ensues which must be collected and washed on a filter. Introduce the washed precipitate, still moist, into a Wedgewood mortar, and add to it tartaric acid 160 grains, rubbing them together until effervescence has ceased; add strong aqua ammoniac in sufficient quantity to dissolve the tartrate of silver (about 2 ounces); then mix in archil ½ fluid ounce; white sugar, 4 drachms; powdered gum arabic, 12 drachms, and add distilled water sufficient, if required, to make 6 fluid ounces of the whole mixture." (Adapted from *Am. Jour. of Pharm.*, XIX, 103).

Silver and Its Salts.—**ARGENTUM, SILVER.** SYMBOL: Ag. ATOMIC WEIGHT: 107.68. *Argentum purificatum, Refined silver.* This well-known metal, called by the ancient alchemists *Luna*, or *Diana*, has been known from biblical times. Pliny mentions the preparation of silver in his writings. It is found in European countries, as Spain, Germany, Norway, and Russia, and also abundantly in Mexico, Peru, and the Western portion of the United States, all of these places yielding very rich argentiferous ores. It is also found native, often forming large masses. It is also found in combination with sulphur and various metals, notably lead, gold, copper, and arsenic, and with iodine, bromine, and chlorine. Sea water contains some silver. A large amount is obtained from *galenite* (lead sulphide), in which silver exists as a frequent accessory constituent. In fact, silver is often produced as a by-product in the production of lead, and *vice versa*. There are several methods of extracting silver from its ores. We will briefly notice but two. The first is the *amalgamation process*. The finely-powdered silver ore, with sodium chloride is put into a reverberatory furnace and roasted, thereby producing silver chloride. The roasted mass is then mixed with water so as to form a thin paste, and agitated with scrap-iron in revolving casks, or cylinders, this process being conducted for many hours. The object of this is to abstract the chlorine, as is shown by the following equation: $2\text{AgCl} + \text{Fe} = \text{FeCl}_2 + \text{Ag}_2$. Then mercury is added, the agitation continuing until a silver-mercury amalgam is produced. This amalgam is then distilled, the mercury passing over, and the silver, often containing gold and copper, remains as a residue. A second method is that known as *cupellation*. If the argentiferous lead ore contains less than $\frac{1}{10}$ of 1 per cent of silver it is first put through Pattison's process of concentration—that is, of melting it and allowing it to partially cool, on which lead crystals separate, which are removed with a strainer-ladle. This leaves a richer alloy behind, which is remelted, and the foregoing process repeated until the alloy is so rich as to contain at least 300 ounces of metallic silver to the ton. This is then *cupelled*—that is, melted, in the presence of an air-blast, on a porous, bone-ash bed, the lead becoming oxidized as litharge, while nearly pure silver remains. Silver obtained in this manner on a large scale is always contaminated with other metals. There are several methods of purification. One of these is to separate the silver in the form of insoluble silver chloride by precipitating a nitric acid solution of the metal with hydrochloric acid and washing the precipitate well with distilled water. Boiling this precipitate with sodium carbonate and glucose reduces it to a powder of metallic silver, which, after being thoroughly washed with acetic acid and distilled water, may be fused as pure silver. Silver is a soft, white, brilliant, tough metal, malleable and capable of taking a high polish. It may crystallize in regular octohedrons. It may be hammered into a thin leaf known as *argentum foliatum* or *silver leaf*, and it is so ductile that it may be drawn into a fine *silver wire*. It is the best conductor of heat and the electrical current. It volatilizes, boils, and distills completely at a white heat produced in the oxyhydrogen flame. At 1000° C. (1832° F.) it fuses with the absorption of oxygen, which is expelled when the silver cools, exhibiting the peculiar phenomenon known as the "spitting" of silver. At the ordinary temperature or at a red heat it refuses to oxidize. Hydrochloric acid does not dissolve silver, but it is easily dissolved by nitric acid. Exposed to the air it becomes superficially tarnished by the hydrogen sulphide of the atmosphere. Sulphur unites with it to form a sulphide, as is seen when a silver spoon is blackened by eggs, onions, etc. Silver precipitated from solutions by various reducing agents may be obtained in several allotropic forms, some soluble, and most of them capable of being powdered by trituration. The modifications are variously colored, green, lilac, blue, reddish-brown, and gold-colored, according to the substance employed as a reducing agent (see Carey Lea, *A. P. A. Proceedings*, 1890-91-92). The density of silver varies, distilled silver being 10.575; pressed silver, 10.57, and fused silver, 10.42 to 10.51. Silver is not used in medicine, except as silver-leaf for coating pills. It is largely used for silvering appliances and instruments, and furnishes silver sutures for the surgeon. It is extensively used in the arts for plating purposes, and is an all-important agency in photography. Combined with varying amounts of copper to give it hardness, it furnishes the silver coin of the world. Of its salts the nitrate is the most important.

ARGENTI CHLORIDUM (AgCl.), Silver chloride.—Prepared by adding to a silver nitrate solution one of common salt in excess (or hydrochloric acid) until it no longer precipitates. A white curdy substance is formed, which agglutinates upon shaking. If exposed to light it darkens. Filter and dry in the dark at a gentle heat. The caustic alkalis, but not the alkaline carbonates, decompose it, producing silver oxide. When found native this salt has been called *horn silver*. It is soluble in 3072 parts of water, soluble in ammonia, and gradually acquires a purple color on exposure to the air. At 260° C. (500° F.) it fuses, and on cooling forms a gray, semi-transparent mass, called *luna cornea*, from its resemblance to horn. Its specific gravity is 5.129; that of the native chloride is 5.552. This salt was recommended by Dr. Perry in *epileptic disease, chronic affections of the bowels*, and as a substitute in many diseases for the nitrate of silver, in doses of 2 or 3 grains every 3 or 4 hours. It is generally used in doses of from 1 to 3 grains 3 or 4 times a day in complaints in which silver nitrate is employed.

SILVER AMMONIO-CHLORIDE crystallizes in cubes when a heated solution of ammonia is saturated with silver chloride, and the mixture allowed to cool in closed bottles. In doses of $\frac{1}{16}$ grain, it has been employed in *sypilitic disorders*.

ARGENTI NITRAS DILUTUS (U. S. P.)—DILUTED SILVER NITRATE.

SYNONYMS: *Mitigated caustic, Argenti et potassii nitras, Lapis infernalis nitratus, Argentum nitricum fuseum mitigatum, Nitrate of silver and potassium.*

Preparation.—"Silver nitrate, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; potassium nitrate, sixty grammes (60 Gm.) [2 oz. av., 51 grs.]. Melt the salts together in a porcelain crucible, at as low a temperature as possible, stirring the melted masses well until it flows smoothly. Then cast it into suitable molds. Keep the product in dark, amber-colored vials"—(U. S. P.).

This preparation is a mitigated form of fused silver nitrate, containing 33 $\frac{1}{3}$ per cent of pure argentic nitrate. If sodium nitrate (Chili saltpeter) be substituted for potassium nitrate the pencils are liable to become hygroscopic on the surface if exposed to moist air. The addition of the potassium salt, like the silver chloride in *molded silver nitrate*, renders it opaque and less fragile than *pure fused argentic nitrate*, and is employed in this form especially as diluent. The diluted silver nitrate of the U. S. P., 1880 (*Lunar Caustic*, No. 3), contained 50 per cent of silver nitrate; a commercial form, containing 67 per cent of silver salt, has long been known as "*Lunar Caustic*, No. 2."

Description and Tests.—"A white, hard solid, generally in the form of pencils or cones of a finely granular fracture, becoming gray or grayish-black on exposure to light in presence of organic matter; odorless, having a caustic, metallic taste, and neutral to litmus paper. Each of its constituents retains the solubility in water and in alcohol mentioned, respectively, under argenti nitras and potassii nitras. An aqueous solution of diluted silver nitrate yields, with a slight excess of hydrochloric acid, a white precipitate, which is readily soluble in ammonia water. The filtrate from this precipitate, when evaporated to dryness, yields a white residue which is completely soluble in water, and this solution affords a yellow, crystalline precipitate with platinic chloride T.S. and a white, crystalline precipitate with sodium bitartrate T.S. If to an aqueous solution of diluted silver nitrate a slight excess of ammonia water be added, it should neither assume a blue color (absence of copper) nor show any turbidity (absence of lead and bismuth). If 1 Gm. of diluted silver nitrate, dissolved in 10 Cc. of water, be mixed with 20 Cc. of decinormal sodium chloride V.S. and a few drops of potassium chromate T.S., not more than 0.5 Cc. of decinormal silver nitrate V.S. should be required to impart to the liquid a permanent red color (corresponding to at least 33 per cent of pure silver nitrate)"—(U. S. P.).

Action and Medical Uses.—Same as silver nitrate (which see); applicable where a mild application is desired.

ARGENTI NITRAS FUSUS (U. S. P.)—MOLDED SILVER NITRATE.

SYNONYMS: *Lunar caustic, Lapis infernalis, Azotas argenticus fusus, Fused nitrate of silver, Nitras argenticus fusus.*

Preparation.—"Silver nitrate, one hundred grammes (100 Gm.) [3 oz. av., 231 grs.]; hydrochloric acid, four grammes (4 Gm.) [62 grs.]. To the silver nitrate, contained in a porcelain capsule, add the hydrochloric acid, and melt the mixture at as low a temperature as possible. Stir well, and pour the melted mass into suitable molds. Keep the product in dark, amber-colored vials, protected from light"—(U. S. P.).

Description, History, and Tests.—*Pure fused nitrate of silver yields a very brittle pencil, hence the allowance of 5 per cent of chloride of silver in molded silver nitrate (as produced by the above process), giving the stick a greater degree of toughness, so that it can be more easily sharpened and used without readily breaking. This form of lunar caustic is the most economical on this account,*

inasmuch as it lacks but little of being pure silver nitrate. The addition of silver chloride to the pure fused silver nitrate was proposed by Dr. E. R. Squibb, in 1858.

The *U. S. P.* describes molded nitrate of silver as follows: "A white, hard solid, generally in the form of pencils or cones of a fibrous fracture, becoming gray or grayish-black on exposure to light in the presence of organic matter, odorless, and having a bitter, caustic, and strongly metallic taste. Soluble at 15° C. (59° F.), with the exception of about 5 per cent of silver chloride, in 0.6 part of water and in 26 parts of alcohol; in 0.1 part of boiling water and in 5 parts of boiling alcohol. The portion left undissolved by water should be completely soluble in ammonia water. A clear, aqueous solution of the salt, decanted from the insoluble portion, should be neutral to litmus paper, and should respond to the tests of identity and purity mentioned under *argenti nitras*. If 0.34 Gm. of molded silver nitrate, dissolved as completely as possible in 10 Cc. of water, be mixed with 20 Cc. of decinormal sodium chloride V.S. and a few drops of potassium chromate T.S., not more than 1 Cc. of decinormal silver nitrate V.S. should be required to impart to the liquid a permanent red color (corresponding to 95 per cent of pure silver nitrate)"—(*U. S. P.*).

Action and Medical Uses.—(See *Silver nitrate*).

ARGENTI OXIDUM (*U. S. P.*)—SILVER OXIDE.

FORMULA: Ag_2O . **MOLECULAR WEIGHT:** 231.28.

SYNONYMS: *Argentum oxydatum*, *Argentio oxide*, *Oxidum argenticum*.

"Silver oxide should be kept in dark, amber-colored vials. It should not be triturated with readily oxidizable or combustible substances, and should not be brought in contact with ammonia"—(*U. S. P.*).

Preparation.—To a solution of nitrate of silver add a solution of caustic potash as long as any precipitate falls; collect the brown precipitate on a filter, wash it repeatedly until the washings are almost tasteless, and dry it at a heat of about 82.2° C. (180° F.). This is practically the process of the *U. S. P.*, 1870. The British process is: "Take of nitrate of silver, in crystals, $\frac{1}{2}$ ounce (av.); solution of lime, $3\frac{1}{2}$ pints (Imp.); distilled water, 10 fluid ounces. Dissolve the nitrate of silver in 4 ounces of the distilled water, and, having poured the solution into a bottle containing the solution of lime, shake the mixture well, and set it aside to allow the deposit to settle. Draw off the supernatant liquid, collect the deposit on a filter, wash it with the remainder of the distilled water, and dry it at a temperature not exceeding 100° C. (212° F.). Keep it in a stoppered bottle"—(*British Pharmacopœia*).

It is essential in these processes that the absence of chlorides and carbonates be insured, lest the product become contaminated with silver chloride or carbonate. The silver nitrate is decomposed, and accordingly, as lime or potassa is employed, the result will be the precipitation of silver oxide and calcium or potassium nitrate. Gregory recommended its preparation from freshly prepared, moist silver chloride, boiling it with solution of potassa (in excess) until diluted nitric acid would dissolve a portion of the product. By this method a black or blue-black powder is obtained.

Description and Tests.—"A heavy, dark, brownish-black powder, liable to reduction by exposure to light, odorless, and having a metallic taste. Very slightly soluble in water, to which it imparts an alkaline reaction, and insoluble in alcohol, but readily and completely soluble in nitric acid without effervescence (absence of carbonate). When heated to about 250° to 300° C. (482° to 572° F.) it is rapidly decomposed, with the evolution of oxygen, and leaving a residue of metallic silver"—(*U. S. P.*). This body readily gives up its oxygen, hence the caution given at the head of this article. When exposed to sunlight it turns black, giving off oxygen, a change which slowly takes place in the mere light, and rapidly when heated. When kept moist it gradually changes to a carbonate. It is insoluble in the fixed alkalis, readily soluble in ammonia, and about 3000 parts of water dissolves 1 part of the oxide. With caustic ammonia it forms a black fulminating powder (*Berthollet's fulminating silver*), on which account the

experimenter should be careful about using ammonia with it, or for preparing it, as it is always attended with danger. Dangerously explosive black crystals of the same are deposited from the ammoniacal solution. "The solution of the oxide in nitric acid should be colorless, and should respond to the reactions and tests mentioned under silver nitrate (see *argenti nitras*). If 0.5 Gm. of the oxide be ignited in a porcelain crucible, it should yield 0.465 Gm. (or 93.1 per cent) of metallic silver"—(U. S. P.).

Action, Medical Uses, and Dosage.—The internal uses of this agent are much the same as those of silver nitrate, though it is less energetic. Oxide of silver has been employed in *neuralgic* and *irritable conditions* of the stomach and bowels, in *dyspepsia*, *water-brash*, *chronic diarrhœa*, and *dysentery*, *epilepsy*, etc. In *uterine diseases*, attended with great irritability and augmented discharges, it has been found especially beneficial, as in *hysteralgia*, *menorrhagia*, *dysmenorrhœa*, and *leucorrhœa*. Its use has occasioned salivation. Pereira states that its long-continued use will occasion a permanent coloration of the skin. A drachm of the oxide to 1 ounce of lard forms an ointment, which has been used in *irritable ulcers*, both syphilitic and non-syphilitic, in *sore nipples*, and in *gonorrhœa*, applied to the urethra by means of a bougie. The dose is from $\frac{1}{2}$ grain to 2 grains, 2 or 3 times a day, in the form of a pill or powder.

ARMORACIA. —HORSE RADISH.

The fresh root of *Cochlearia Armoracia*, Linné (*Cochlearia rusticana*, Lamarck; *Armoracia rusticana*, Gærtner; *Armoracia sativa*, Heller).

Nat. Ord.—Cruciferae.

COMMON NAME: *Horseradish*.

Botanical Source.—Horseradish root, very tenacious of life, is a perennial, thick, tapering, white, long, acrid, and from which arise many large leaves. From the center a round or angular, smooth, erect, branching stem arises, about 2 feet in height; those branches which flower are corymbose, smooth, and angular. The radical leaves are nearly a foot long, half as wide, oblong, crenately-toothed, waved, sometimes pinnatifid, of a dark-green color, and upon long, channeled petioles; the cauline leaves are smaller, lanceolate, dentate, or incised, sessile, sometimes entire, and without footstalks; the lower ones are often pinnatifid. The flowers are numerous, small, white, peduncled, and borne in terminal corymbose racemes. Calyx ovate, spreading, and equal at the base; sepals four, concave. Petals obovate, obtuse, entire, claw-like. Stamens without teeth, the length of the calyx; anthers cordate; silicle sessile, oblong, or ovoid-globose, and compressed; dissepiment thin; valves ventricose, thickish; cells many seeded; seeds not bordered, and cotyledons flat and accumbent (G.—W.—L.).

History and Description.—This well-known succulent plant is a native of Europe, and extensively cultivated for the use of its root as a condiment. It flowers in June. The fresh root is the official part, and should be dug in the autumn, as its acrimony is then the strongest; it may be preserved for some time fresh by burying it in a cool place in sand. The root is whitish-yellow externally, white internally, of various lengths tapering to a point, from $\frac{1}{2}$ inch to 2 inches or more in diameter at its thickest part, fibrous, fleshy, succulent, of a very pungent taste and odor, producing a flow of tears, and when smelt, violent sneezing. The root is surmounted by several annulated heads. It breaks with a short fracture. Water, alcohol, or vinegar extracts its properties, which are due to the presence of a volatile oil, and which is dissipated by heat or desiccation. Fresh aconite root has been eaten by mistake for horseradish, probably on account of their somewhat similar appearance and odor when fresh.

Chemical Composition.—This root contains a volatile oil, its principal constituent, which passes over when the root is distilled with water; it is of a light-yellow color, possessing the pungent properties of the plant in a high degree, causing irritation and even blistering when in contact with the skin. It is supposed to be perfectly identical with the volatile oil of mustard, and is obtained in minute proportion, 6 parts only of the oil being procured from 10,000 of the root. It is believed not to exist already formed in the unbroken root, but to be

developed by the mutual reaction of its constituents when the root is bruised. Dr. A. W. Hoffman, however, has found these two oils to be entirely different, the oil of *Cochlearia* boiling at 160° C. (320° F.), while the oil of mustard boils at 146.6° C. (296° F.); treated with ammonia the oil of horseradish yields a beautifully crystallizing substance, *thiosinamin*, which fuses at 135° C. (275° F.). The dried root possesses no pungency, and yields no volatile oil when distilled with water, unless white mustard be added, the *myrosin* of the mustard supplying some necessary principle destroyed by desiccation. In addition the root contains a bitter resin, sugar, gum, starch, extractive, albumen, acetic acid, acetate and sulphate of calcium, water, and lignin. Various other salts and acids were found in the ash by Hilger.

Action, Medical Uses, and Dosage.—Stimulant, sialagogue, diuretic, antiscorbutic, and rubefacient. The pungent and acrid nature of the fresh root, with the faucial and nasal irritation and consequent lachrymation, are well-known effects to those who use it as a condiment. Burning pain at the epigastrium, nausea, and vomiting follow an immoderate dose. Externally applied it is rubefacient and may vesicate. It promotes all the secretions, the urinary in particular, and stimulates the stomach when this organ is enfeebled. By its sialagogue and stimulant effects upon the gastric membranes it promotes digestion. The infusion is emetic. It has been used with advantage in chronic affections attended with debility of the digestive organs, and of the general system, as in *paralysis*, *rheumatism*, *dropsy*, and as an antiscorbutic in *scurvy*. In *dropsy* an infusion of the root in cider, and drank as warm as could be borne, in large quantities and freely, the patient being warmly covered up, has caused copious diuresis and diaphoresis, and cured the disease in a few weeks; the operation being repeated nightly, or as the strength of the patient would permit. Horseradish was formerly much employed to produce abortion, frequently effecting this object, when other internal agents failed; it was used as follows: A saturated infusion of the recent roots in whiskey was made, of which 4 fluid ounces was the dose, repeating it 3 or 4 times every day, and continuing its use until the desired effect was produced. Locally the vinegar infusion is said to remove *tan* and *freckles*. The grated root, with sugar and water to form a syrup, is excellent for *hoarseness*; a spoonful or two may be swallowed as occasion requires. It has been also used externally as a rubefacient. Dose of the root grated, from 1 to 2 drachms.

The *Cochlearia officinalis*, or *Scurvy grass*, is seldom used in medicine; it possesses similar properties.

Specific Indications and Uses.—Hoarseness from relaxed faucial tissues; gastric debility. It is a remedy for atonic conditions only.

ARNICA.—ARNICA.

The flower heads, rhizome, and roots of the *Arnica montana*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Arnica*, *Leopard's bane*.

ILL. SITUATION: Bentley and Trimen, *Med. Plants*, 158.

Botanical Source.—*Arnica montana* is a rather hairy plant, with a dark or blackish root, from which are given off numerous radicles. The stem is simple, pubescent, rough, obscurely angled, striated; one to three-headed and from 10 to 12 inches in height. The leaves are entire and opposite; the radical ones obovate or oblong, ciliated, five-nerved; the cauline in one or two pairs. The flowers are large, orange-yellow; in erect or drooping heads. The involucre is cylindrical and rough with glands. There are many tubular, five-lobed disk-florets, and about fourteen strap-shaped, three-toothed, striated ray-florets, downy at the base. The achenia are somewhat cylindrical, downy, ribbed, and blackish, with a straw-colored, hairy pappus.

Arnica montana.

History and Description.—This perennial herb inhabits Siberia; also the cooler parts of Europe from the sea coast to the limits of constant snow; in moist, shady situations, flowering in June and July; it is likewise found in the northwestern parts of the United

States. The whole plant has been used in medicine; more especially the flowers. The flowers are compound, radiated, yellow, with a calyx of linear equal follicles, the length of the disc, ligulate, floscules twice the length of the disc, two lines broad, three-toothed, with a sessile pappus, fragile and somewhat scabrous; taste acrid and bitterish; the dust is unpleasant, and causes sneezing. The odor is unpleasant, but is much diminished, as well as the taste, by drying. They yield their properties to water or alcohol. The dried root is about the thickness of a small quill, flexuous, bark brown externally, rugose longitudinally, with a somewhat hard, whitish wood, larger pith, and long, dense radicles on one side; its taste is aromatic, acrid, and slightly bitter. It should be gathered in the spring. Arnica flowers are liable to adulteration with various composite flower-heads, as anthemis, inula, and calendula. As these differ considerably botanically, there will be no difficulty in detecting the spurious flower-heads.

The *Pharmacopœia of the United States* gives the following descriptions of the flowers and rhizome:

ARNICÆ FLORES (*U. S. P.*), *Arnica flowers*.—"Heads about 3 Cm. (1½ inches) broad, depressed-roundish, consisting of a scaly involucre in two rows, and a small, nearly flat, hairy receptacle, bearing about 16 yellow, strap-shaped, ten-nerved ray-florets, and numerous yellow, five-toothed, tubular disk-florets, having slender, spindle-shaped achenes, crowned by a hairy pappus. Odor feeble, aromatic; taste bitter and acrid"—(*U. S. P.*).

ARNICÆ RADIX (*U. S. P.*), *Arnica root*.—"Rhizome about 5 Cm. (1½ inches) long and 3 or 4 Mm. (¼ to ½ inch) thick; externally brown, rough from leaf-scars; internally whitish, with a rather thick bark, containing a circle of resin-cells, surrounding the short, yellowish wood-wedges, and large, spongy pith. The roots numerous, thin, fragile, grayish-brown, with a thick bark containing a circle of resin-cells. Odor somewhat aromatic; taste pungently aromatic and bitter"—(*U. S. P.*).

Chemical Composition.—Pfaff found the root to contain volatile oil, acrid resin, extractive, gum and woody fiber. Chevallier and Lassaigue found the flowers to contain resin, a bitter, nauseous substance resembling *cytisin*, gallic acid, a yellow coloring matter, albumen, gum, chloride and phosphate of potassium, traces of sulphates, carbonate of calcium, and silica (T.).

In 1851 Mr. Bastick announced the existence of an alkaloid in the flowers, which he obtained in small quantity and called *arnicina* (*arnicine*). It is not volatile, bitter, slightly soluble in water, but more so in alcohol and ether. Its hydrochlorate is crystallizable (P.). Two bodies, known as *arnicin*, and derived from both the flowers and rhizome, have subsequently been isolated by two observers—Pavesi in 1859, and Walz, in 1861. The principles are totally unlike, though bearing the same name. Pavesi's *arnicin* is a disagreeably bitter, viscid resin, of a deep-yellow color, dissolving easily in alkaline solutions, from which acids precipitate it, and it dissolves sparingly and with difficulty in both ether and alcohol. Walz's *arnicin* (sometimes written *arnicine*, though different from Bastick's alkaloid), on the contrary, is an acrid, amorphous, golden-yellow mass, dissolving sparingly in water, and readily soluble in ether and alcohol. Alkalies also dissolve it. Recently *arnicine* was isolated from the flowers by Börner (*Am. Jour. of Pharm.*, 1893), who found for it the formula, $C_{12}H_{22}O_2$. It exists in the flowers to the extent of 4 per cent, and is obtainable from a concentrated acetone solution as a micro-crystalline mass, deliquescent after prolonged exposure, melts at 40° C. (104° F.), and boils at 83° C. (181.4° F.); is golden-yellow, and easily soluble in ether, alcohol, acetone, benzole, insoluble in water and alkalies. He also found fat (glycerides of palmitic and lauric acids), and a hydrocarbon of the marsh-gas series. A small amount of *angelic* and *formic* acids have been obtained from arnica. Dragendorff obtained 10 per cent of *inulin* from the root (*Pharmacographia*).

The volatile oil, which is obtained most plentifully from the green rhizome, abounds to the extent of from 0.5 to 1 per cent, and has a specific gravity of 0.990 to 1.000 at 15° C. (59° F.), and contains *iso-butyric acid*, *phlorol-ester*, and *thymo-hydro-quinone-dimethyl-ether* (Schimmel & Co.'s *Semi-Annual Report*, October, 1893).

Action, Medical Uses, and Dosage.—Locally arnica is irritant, the preparations of the flowers being most powerful. Strong preparations should not be

applied full strength, for in some instances of tender skin, or in accidents occurring after its use, an erysipelatous inflammation has followed. Even when used as a local dressing for wounds dangerous inflammation, with vesication, has occurred.

Internally, in large doses, arnica causes heat in the throat, nausea, vomiting, purging, spasmodic contractions of the limbs, difficulty of respiration, and sometimes inflammation of the alimentary canal, and coma. There is no known antidote to its poisonous influences; vegetable acids have been recommended. Two fluid ounces of the tincture has produced death.

In small doses arnica accelerates the pulse, increases the perspiration, excites a flow of urine, and is said to occasionally cause headache and giddiness. It is esteemed as a stimulant in *typhoid fever* and other *adynamic febrile diseases*, in *chronic palsy*, and *amenorrhœa*; also as a tonic in *chronic rheumatism*, and as a tonic and diuretic in the asthenic forms of *dropsy*. In *intermittent fever* it has proved very successful; also in *nyctalopia* and *amaurosis* (the best remedy); and is reputed to be highly efficacious in *constitutional derangements* caused by powerful shocks to the brain, from thumps, kicks, etc., in *internal pains*, and *congestions from bruises*, deficient action of parts, etc. It has also been recommended in cases of deficient nervous sensibility, languid vascular action, and almost every disease where there is debility, torpor, or inactivity of function. The conditions calling for arnica are those with evidences of spinal innervation. As a specific stimulant to the spinal nerves it is exceedingly prompt in advanced stages of disease, with feeble respiratory power and sleeplessness due to the same cause; also in lack of control over the voluntary discharges. It is indicated in *low typhoid states*, and in low forms of *typhus fever*, *diarrhœa*, and *dysentery*, always where there is marked depression and debility. In *typhoid pneumonia*, with marked asthenia and feeble circulation, great depression, low-muttering delirium, and tongue dry and loaded with foul mucus, it is one of the most efficient agents in use. Its action upon enfeebled respiratory efforts is much like that of phosphorus, as is also its effects in *sexual debility* from abuse, and in *paralytic states of the orifices* without active inflammation, particularly in the aged. Small doses are very efficient in *anemia* with weak circulation, general debility, and especially when associated with *diarrhœa* and *dropsy*, provided no inflammation is present (Locke). It is a remedy for *hectic fever*, with *diarrhœa* or excessive sweating. In *rheumatism*, with cold skin and debility, it arouses nervous action and stimulates excretion. It is a good agent in *myalgia*, and one of the best in muscular soreness and pain dependent upon strains, over-exertion, or other injuries. Here it should be applied locally in weak solutions and taken internally. The *nervous headache* of the debilitated and depressed calls for it, as does debility of the cardiac muscle due to excitement, over-activity, or "*heart-strain*." The dull aching in the *præcordia*, due to such over-action, is relieved by it. Prof. Scudder (*Spec. Med.*) writes: "I have frequently prescribed it for lame back, backache, and feelings of debility and soreness in the small of the back. It is only useful in those cases where there is feebleness, with deficient circulation; but in these the influence is direct and permanent."

Externally arnica is used in the form of an infusion, a fomentation, or diluted tincture of the flowers, both to prevent and discuss *local inflammations*, to remove *ecchymosis*, and as a dressing for *cuts*, *lacerations*, *contusions*, etc. For this purpose the infusion is attended with the least danger. The late Prof. J. M. Maisch prepared a fluid extract of arnica, which has been found very useful as an application for the bites of mosquitoes and other insects, thus: Exhaust powdered arnica flowers, 1 pound, with diluted alcohol; filter; evaporate to the consistence of an extract, and redissolve this in 2 pints of ordinary alcohol. By adding 4 ounces of this fluid extract to 1 pint of glycerin, placing the mixture on a water-bath, so as to expel the alcohol, an elegant *glycerole of arnica* may be made; it may be made stronger if desired. This may be used in all cases where the local action of arnica is desired.

Dose of the powder, 5 to 10 grains, 2 to 4 times a day; of the infusion, made by adding $\frac{1}{2}$ ounce of the flowers to 1 pint of water, from $\frac{1}{2}$ fluid ounce to 1 fluid ounce; of the extract, which is an excellent form of administration, from 1 to 10 grains, 4 or 5 times a day. Of specific arnica, from 1 to 10 minims. In preparing an infusion of the flowers they should be loosely tied in a bag in order to

prevent the down or fine fibers from getting into the infusion, or else they will cause troublesome irritation of the throat, nausea, and vomiting.

Specific Indications and Uses.—Muscular soreness and pain from strains or over-exertion; advanced stage of disease, with marked enfeeblement, weak circulation, and impaired spinal innervation; embarrassed respiration; lack of control over urine and feces; sleeplessness from impeded respiration, and dull præcordial pain from "heart-strain;" muscular pain and soreness when the limbs are moved; tensive backache, as if bruised or strained; cystitis, with bruised feeling in bladder, or from a fall or blow; headache, with tensive, bruised feeling and pain on movement; hematuria, with dull, aching lumbar pain, or from over-exertion. All cases of debility with enfeebled circulation.

Related Species.—*Arnica foliosa*, Nuttall. Northern and western United States, as far south as Colorado, growing in the mountain districts. This and the following species have flowers which resemble very much those of *Arnica montana*.

Arnica alpina, Olin, United States. Distribution same as *A. foliosa*.

Arnica nudicaulis, Elliott (*Arnica Claytonia*, Pursh). United States, from Virginia to Florida, growing in damp, pine barrens and wet sands. Flowers in April and May.

Arnica mollis, W. J. Hooker (*Arnica lanceolata*, Nuttall; *Arnica Chamissonis*, Lessing.) Mountainous regions of northern states, especially in New York and New Hampshire. Blooms in July. This and the preceding species are thought to have properties resembling those of *Arnica montana*.

ARSENI IODIDUM (U. S. P.)—ARSENIC IODIDE.

FORMULA: AsI_3 . MOLECULAR WEIGHT: 454.49.

SYNONYMS: *Arsenous iodide*, *Iodide of arsenic*, *Arsenii iodidum*, *Arsenicum iodatum*, *Arsenium iodatum*, *Arsenici iodidum*, *Ioduretum arseniosum*.

Preparation.—Sixty (60) parts of pure, powdered, metallic arsenic are mixed with three hundred (300) parts of iodine, and the mixture fused in a flask. The operation must be performed under a flue, with a good current of air, and the operator must avoid inhalation of the fumes. The foregoing method is in accordance with the U. S. P., 1880. Arsenic iodide forms an orange-red volatile, crystalline solid, which is dissolved by cold water, and is a powerful preparation, combining the effects of arsenous acid and iodine, and requiring great caution in its use.

Description and Tests.—The Pharmacopœia directs: "Glossy, orange-red, crystalline masses, or shining, orange-red, crystalline scales, having an iodine-like odor and taste, and gradually losing iodine on exposure to air and light. Soluble at 15° C. (59° F.) in 7 parts of water and in about 30 parts of alcohol; also soluble in ether and in carbon disulphide. The salt is gradually decomposed by boiling water and by boiling alcohol. By heat it is completely volatilized; and if it be heated with diluted nitric acid, vapor of iodine will be evolved. The aqueous solution of the salt has a yellow color, is neutral to litmus paper, and, on standing, gradually decomposes into arsenous and hydriodic acids. On adding hydrogen sulphide T.S. to the solution acidulated with hydrochloric acid, a lemon-yellow precipitate is produced"—(U. S. P.). If prepared by fusion, orange-red masses result, while the crystalline scales are produced by sublimation or by crystallization. "Arsenic iodide should be kept in glass-stoppered vials, in a cool place, protected from light"—(U. S. P.).

Action, Medical Uses, and Dosage.—In small doses this agent is alterative; in excessive doses an irritant poison like arsenic. The symptoms from small doses are dryness of the throat and intestinal canal, perspiration, and headache. Gastric derangement and faucial dryness are signals to stop its administration. Said to be useful in *secondary syphilis*, *lupus*, *lepra*, and other obstinate affections of the skin, with dry, burning, itching, and scaly eruptions, or scrofulous enlargement of the glands (Webster). Like arsenic it undoubtedly retards the development of *scirrhus of the breast* in debilitated individuals. Internally its dose is $\frac{1}{4}$ grain, 3 times a day, in form of pill, gradually increasing to $\frac{1}{2}$ grain. Biett's ointment for cutaneous diseases is made of 1 part of the iodide to 192 parts of lard, of which 1 drachm may be used at a time. The solution may be made extemporaneously by mixing together 1 part of compound solution of iodine and 4 parts of Fowler's solution, of which the dose is from 3 to 6 drops.

In epidemical hot weather *diarrhœa* of children, and in the *marasmus* following prolonged *cholera infantum*, the 6 x trituration, in 2 or 3-grain doses, every 2 hours, is recommended by Webster. *Hay fever*, and old fetid and bleeding *nasal catarrh*, extending to the throat, is treated with the 3 x trituration by Hale.

Specific Indications and Uses.—"Chronic eczema, dyspepsia, feeble nutrition, weakness, debility, profuse, acrid, nasal discharge, causing erosion where it comes in contact with the skin. Three to 5 grains, third trituration, 3 times a day" (Watkin's *Comp. of Ec. Med.*).

Arsenic and Its Compounds.—**ARSENUM**, *Arsenium*, *Arsenicum*, *Arsenic*. Symbol: As. Atomic Weight: 74.9. Specific gravity, 5.73 to 5.96. This is a metallic substance of bluish-white color, not unlike that of steel, with a great deal of brilliancy. It is odorless, but when heated emits a strong odor of garlic. It is the softest of all the metallic bodies, and is very brittle and easily reduced to powder. At 180° C. (356° F.) it sublimates without melting. It may be kept under water without alteration; but when exposed to the air it soon loses its luster, and often becomes black and falls into powder. It combines with oxygen in two proportions, forming compounds which possess acid properties; namely, *arsenous acid* and *arsenic acid*, both combining with bases, forming *arsenites* in the former, and *arsenates* in the latter case.

Arsenic exists free in small amounts, but is most abundant as arsenide of iron, nickel, or cobalt, and still more plentiful in the arsenic sulphides—*realgar* (As_2S_2) and *orpiment* (As_2S_3). It exists in large amounts in arsenical pyrites, or *mispickel* ($FeS_2 \cdot FeAs_2$). Native arsenic uncombined is often known as *flystone* (*cobaltum*). *Cobalt-glance* has the composition, $CoS_2 \cdot CoAs_2$, and *tin-white cobalt*, $CoAs_2$. From these ores, especially arsenical pyrites, metallic arsenic is obtained by sublimation and purified by resublimation with the addition of some powdered charcoal.

ARSINE, *Hydrogen arsenide* (AsH_3), *Arseniuretted hydrogen*.—This colorless, poisonous gas is produced when arsenic or arsenous acids or oxides, or their salts, are acted upon by hydrogen in a nascent condition. It is familiar as the gas generated in applying *Marsh's Test for Arsenic* (see *Acidum Arsenosum*). This gas has a strong odor of garlic, and when ignited burns with a bluish flame, evolving white, cloud-like vapors of arsenous oxide, at the same time liberating water. If, however, a cold plate of porcelain be held in the flame close to the orifice of the emission tube metallic arsenic will be deposited upon it as a mirror-like film. Glass or a plate may be used for the same test. Arseniuretted hydrogen has a specific gravity of 2.695.

REALGAR, *Red orpiment*, *Disulphide of arsenic* (As_2S_2).—This mineral sulphide of arsenic occurs in beautiful scales of an orange-red color. It is volatilized by heat. It may be artificially prepared by melting together 3 parts of sulphur and 5 parts of arsenic, when sulphur dioxide will be evolved. If ignited it produces a blue flame. A pyrotechnic mixture may be made of 2 parts of red orpiment, 7 parts of sulphur, and 25 parts of potassium nitrate, the latter, when mixed with red orpiment, causing it to give a white flame. This preparation is also used for signaling. It has been used as a pigment.

ORPIMENT, *Auripigmentum*, *Trisulphide*, or *Yellow sulphide of arsenic* (As_2S_3), crystallizes in monoclinic prisms of yellow color, and is the same substance as that obtained artificially when a solution of arsenous acid in water, acidulated with hydrochloric acid, is precipitated by hydrogen sulphide gas. It has been used as a pigment under the name of *King's yellow*, but its use is now abandoned, owing to its poisonous properties, as it contains a large percentage of arsenous acid. It is prepared commercially by subliming a mixture of 7 parts of powdered arsenic trioxide and 1 part of sulphur. Chrome yellow is now used in its stead (R. and S.). Mixed with a large quantity of slaked lime it acts as a depilatory. It is chiefly used in making pyrotechnic mixtures.

ARSENIOUS BROMIDE ($AsBr_3$).—This salt is produced by the union of arsenic and bromine through the intervention of carbon disulphide. It is a deliquescent, crystalline body, devoid of color, and has a distinctive and peculiar odor. It fuses at near 20° C. (68° F.), and begins to boil at 202° C. (428° F.). Its density is 3.86. In contact with water it is decomposed, producing bromide of hydrogen and trisulphide of arsenic. This remedy was employed in solution by Clemens for the treatment of *diabetes*.

Specific indications and uses.—"Choreic tendencies, asthma, anemia, soft, flabby skin. Ten to 20 drops (solution) in 4 fluid ounces of water; teaspoonful 3 times a day" (Watkin's *Comp. of Ec. Med.*).

ARSENIOUS CHLORIDE ($AsCl_3$).—An intensely poisonous, oily fluid, without color, produced by heating together and distilling arsenous acid and hydrochloric acid. It is volatile, and when dissolved in water is at once resolved into the acids used in preparing it, namely, arsenous and hydrochloric acids. Its boiling point is 134° C. (273.2° F.); its density, 2.206.

ARSENIC OXIDE (As_2O_3), *Arsenic pentoxide*, *Anhydrous arsenic acid*.—If arsenous acid be heated with an aqueous solution of nitric acid, arsenic acid (AsO_4H_3) is produced. If this solution be evaporated, and the residue heated to 100° C. (212° F.), *ortho-arsenic acid* (AsO_4H_2) is left. It occurs as a white, heavy, solid mass, which, by its deliquescence, is converted into a corrosive, oily-appearing fluid, really arsenic acid, in concentrated solution. *Ortho-arsenic acid* (AsO_4H_2), heated to a temperature of 180° C. (356° F.), loses water and forms *pyro-arsenic acid* ($As_2O_5H_2$). Upon further heating to a temperature of 200° C. (392° F.), water is again given off, resulting in the formation of *meta-arsenic acid* (AsO_3H_2), a crystalline mass. In this respect the analogy between arsenic and phosphorus is evident. Unlike phosphorus, however, meta-arsenic acid, upon further heating to a temperature just below red-heat, again loses

water and forms arsenic pentoxide. This, when subjected to a red heat, gives off oxygen and leaves arsenous oxide (As_2O_3). Water changes it into arsenic acid. *Meta-arsenic* and *pyro-arsenic acids* may also be converted into arsenic (ortho-arsenic) acid when brought in contact with water. This compound, while poisonous, is less so than the lower oxide. It, as well as arsenic acid, is consumed considerably, chiefly as an oxidizing chemical in the production of aniline red (see *Aniline Dyes*). Arsenic acid forms salts (arsenates) corresponding with those of phosphoric acid.

ARUM.—INDIAN TURNIP.

The partially dried corm of the *Arisæma triphyllum*, Torrey (*Arum triphyllum*, Linné).

Nat. Ord.—Araceæ.

COMMON NAMES: *Indian turnip*, *Jack-in-the-pulpit*, *Dragon-root*, *Wake-robin*.

ILLUSTRATIONS: Willdenow, *Sp. Plant* IV, 480, as *Arum triphyllum*; also as same in Bigelow, *Amer. Med. Bot.* I, 52; Johnson's *Med. Bot. of N. A.*, 263.

Botanical Source.—Indian turnip has a round, flattened, perennial, rhizome (cormus), the upper part of which is tunicated like the onion, the lower and larger portion tuberous and fleshy, giving off numerous long, white radicles in a circle, from its upper edge; the under side is covered with a dark, loose, wrinkled epidermis. The spathe is ovate, acuminate, convoluted into a tube at the bottom, flattened and bent over at the top like a hood, varying in color internally, being green, dark-purple, black, or variegated with pale-greenish stripes on a dark ground, supported by an erect, round, green, purple, or variegated scape, invested at the base by the petioles and their acute sheaths. The spadix, situated within the spathe, is club-shaped, shorter than the spathe, rounded at the end, green, purple, black, or variegated, contracted into a narrow neck at the base, where it is surrounded by the stamens or ovaries. In the fertile plants it is invested with roundish, crowded ovaries, each tipped with a stigma; in the barren its base is covered with conical, fleshy filaments, each bearing from 2 to 4 circular anthers. Plants which are perfectly monoecious, and which are the least common, have stamens below the ovaries. The upper portions of the spadix wither, together with the spathe, while the ovaries grow into a large, dense bunch of shining berries of a bright scarlet color. The leaves, generally one or two, are ternate and stand on long, sheathing footstalks. The leaflets are oval, mostly entire, acuminate, smooth, paler on the under side; becoming glaucous as the plant grows, the two lateral ones being somewhat rhomboidal.

Arisæma triphyllum.

Description and History.—The corm is subglobular, depressed, or turnip-shaped, from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches in diameter. The base is free, flat and corrugated, while the upper portion has a zone of rootlets surrounding the corm. Within it is milky-white, amylaceous, or mealy, while externally it is of a dark, brownish-gray color. It has no odor, and possesses an acrid, burning taste. When first dug it is fiercely acrid—too much so for internal employment; upon masticating it, it causes a persistent and intensely acrid impression upon the tongue, lips, and fauces, like that of a severe scald, with considerable prickling, and which is followed by slight inflammation and tenderness. Milk relieves this sensation, greatly modifying its intensity. It exerts no such influence upon the external skin, except upon long and continued application. The ordinary solvents, ether perhaps excepted, do not extract the acrid element, which is exceedingly volatile, the root rapidly losing its acrimony by age. It should always be used when partially dried. Its activity may be preserved for a year or more by burying the root in sand. This plant inhabits the American continent, in both hemispheres, being found in wet locations, and flowers from May to July. The whole plant is acrid, but the root is the only part employed.

Chemical Composition.—In addition to its acrid principle it contains a large proportion of starch; also, gum, albumen, saccharine matter, calcium and potas-

sium salts, and extractive. When the acrid property is driven off by heat, the root yields a pure, delicate, amylaceous matter, resembling the finest arrowroot, very white and nutritive. That raphides of oxalate of calcium give to the corn its acridity has been asserted by Weber (1891).

Action, Medical Uses, and Dosage.—(For action of the fresh root see above.) Acrid, expectorant, and diaphoretic. Recommended in *flatulence, croup, whooping-cough, stomatitis, asthma, chronic laryngitis, bronchitis, pains in the chest, colic, low stage of typhus*, and various affections connected with a cachectic state of the system. Externally it has been used in *scrofulous tumors, tinea capitis*, and other *cutaneous diseases*. Its action in the prostration of low fevers with wild delirium is due to its effects upon the cerebral centers. It is reputed useful in *cerebro-spinal fever* and *scarlatina*, when delirium is present, when the tongue is swollen, red, and painful, and the buccal membranes inflamed. *Chronic laryngitis*, or *minister's sore throat*, with sudden hoarseness and aphonia, is specifically influenced by arum. It is also useful in *ulceration of the larynx and pharynx*. It is a good remedy, internally and locally, for aggravated red *sore throat*. The powdered root may be given in 10-grain doses, increased, if required, to 20 or 30 grains, and repeated every 3 or 4 hours. It may be taken in sweetened mucilage, syrup, or honey. Specific arum, $\frac{1}{16}$ to 10 drops. Its specific effects are best obtained by minute doses of the specific arum — $\frac{1}{16}$ to $\frac{1}{2}$ drop doses.

Specific Indications and Uses.—Hoarseness and aphonia, with burning and constriction of the throat, and thin, ichorous, nasal discharge; intensely sore throat, with bleeding and fetor; a feeling of fullness or swelling of the mouth, throat, and tongue, the latter being red and sensitive.

Related Species.—*Arum maculatum*, Linné, *Cuckoo-pint*.—Europe. This plant is somewhat similar to Indian turnip, possessing the same chemical components, with the addition thereto of saponin, fixed oil, and resin. Large doses of it have produced inflammation of the bucco-cesophageo-gastric tract, and fatal effects are recorded from its use. In times of famine the peasants have used the prepared corn in making bread. Small amounts of a starchy material were at one time prepared from it on the Isle of Portland, England, and sold on the market as "*Portland sago*" or "*Portland arrowroot*." It was formerly official in the *Dublin Pharmacopæia*.

Colocasia antiquorum, Schott. (*Arum Colocasia [esculentum]*, Linné. *Caladium acre*, Robert Brown. *Caladium esculentum*, Ventenat). The Fijian "*Taro*." This plant is cultivated in the Levant for its leaves, which are eaten like spinach (*Treasury of Botany*). The root well cooked is eaten by the Fijis. They call it *taro* and prefer to eat it cold. The whites prefer it roasted and served hot. These roots are largely used in Japan for food, having been catalogued in a Japanese exhibit in London as "*Japanese potatoes*" (Maiden, *Nat. Plants of Australia*). Styptic and astringent. Tubers used in India as foenentations in *rheumatism*. A single application of the juice of a slightly roasted petiole checks *otorrhœa* in children (Dymock, *Mat. Med. Western India*). The same arrests arterial hemorrhage (*Pharin. India*). Cultivated in gardens in the United States for decorative effects.

Colocasia macrorrhiza, Schott. Tubers baked or roasted in cakes called *hakkin*, and used as food by the Queensland natives.

Typhonium Brownii, Schott. (*Arum orizense*, Robert Brown). New South Wales to North Australia. Used as food like the *Colocasia macrorrhiza*.

Richardia æthiopica, Kunth. (*Calla æthiopica*, Linné.) *Egyptian calla*. The starchy tuber of this ornamental plant has been used as food.

Rhaphidophora ritiensis, Seemann. Nat. Ord.: *Araceæ*. Fiji Islands. Source of *Tonga*, which is a mixture of leaves, bark, and fibrous wood sent to market tied up with cocoanut fiber. The stem of the tree is scraped to obtain the drug. It contains starch, raphides, potassium chloride, and *tongine*, a volatile alkaloid. Introduced by Ringer and Murrell as a remedy for *neuralgia*. The bark in the above mixture comes from a tree of another order (*Verbenacæ*) — the *Premna taitensis*, De Candolle. It contains fat, volatile oil, sugar, and pectin (Gerard).

ASAFETIDA (U. S. P.)—ASAFETIDA.

"A gum-resin obtained from the root of *Ferula fetida* (Bunge), Regel" — (U. S. P.). (*Ferula Narthex*, Boissier; *Scorodosma fetida*, Bunge; *Ferula asafetida*, Linné; *Narthex asafetida*, Falconer; *Ferula Scorodosma*, Bentley and Trimen).

Nat. Ord.—*Umbelliferae*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 127.

Botanical Source.—This plant has a perennial fusiform root, several inches in diameter, with a coarse, hairy summit, either simple like a parsnip, or with

one or more forks; its bark is wrinkled, blackish; its internal structure fleshy and white, containing a large amount of a thick, milky, fetid, alliaceous juice. The leaves are radical, springing up in the autumn, growing vigorously during the winter, withering at the close of spring. They are several in number, $1\frac{1}{2}$ feet long, shining, coriaceous like those of lovage, glaucous-green, pinnated, with pinnatifid segments whose lobes are oblong and obtuse; the petioles terete, and channeled only at the base. The stem is herbaceous, 8 or 10 feet high, and about 6 inches in circumference at the base; it is solid, smooth, and clothed with membranous sheaths. The general umbels have from 10 to 20 rays; the partial ones 5 or 6 flowers. The flowers are pale-yellow, succeeded by a flat, thin, reddish-brown fruit, like that of parsnip, only rather larger and darker, and slightly hairy or rough. The plant varies somewhat owing to its location and the character of the ground (L.—Falconer—Royle).

Fig. 31.

Ferula foetida, Bunge (*Narthex asafetida*, Falconer).

History.—This plant is indigenous to Persia and Thibet. It was personally examined and imperfectly delineated by Kämpfer, in 1687. According to Polak it is principally gathered in the country from Ispahan to Mahior, and that part which separates Abedeh and Murgab, and is much used as a culinary article, and to remove spasm. In several provinces it is planted in gardens to keep away destructive insects. The gum-resin is obtained by incisions into the upper part of the root, or by slicing it successively in small pieces; plants under four years are not made use of, as they yield but little, if any, of the juice. When the leaves begin to decay, the root-leaves and stem are twisted off close to the root, and the soil is removed from its crown. About 40 days afterward a thin slice is cut off transversely from its top, and a milky juice of a fetid, alliaceous odor gradually exudes. In about two days, or when this exudation has become hardened, it is scraped off, and another thin slice removed as before, from which juice again flows, and this process is repeated until no more juice can be obtained; while this collection is going on the root is constantly protected from the solar rays. The concrete juice from several plants are then put together, further hardened, and disposed of for home use or foreign exportation. Most of the gum used in medicine comes from Afghanistan and Persia. The purest gum is known by the vernacular, *hing*. According to Dymock the brown asafetida is produced by the *Ferula alliacea*, Boissier. The product principally found in our markets is that shipped from Bombay and known as *hingra*, a product largely admixed with stones and dirt. Dymock states that sliced potatoes have been used to adulterate asafetida.

Description.—This gum-resin is brought to America in packages of various weights, but seldom less than 50 or 60 pounds each. The *U. S. P.* describes it as occurring "in irregular masses composed of whitish tears, which are imbedded in a yellowish-gray or brownish-gray, sticky mass. The tears, when hard, break with a conchoidal fracture, showing a milk-white color, which changes gradually, on exposure, to pink, and finally to brown. It has a persistent, alliaceous odor, and a bitter, alliaceous, acrid taste. When triturated with water it yields a milk-white emulsion, which becomes yellow on the addition of ammonia water. It is partly soluble in ether, and at least 60 per cent of it should dissolve in alcohol"—(*U. S. P.*). Those masses should be selected which are clear, of a pale, reddish color, and variegated with a great number of white tears, and on burning they should not have an odor of pitch. Berzelius and Thomson give as its specific gravity, 1.327. Age hardens it and impairs its properties; it becomes pulverable at a diminished temperature, as in frosty weather; in warm weather it becomes soft and adheres to the pestle. Moderate heat softens it so far that it may be squeezed through a coarse cloth, and freed from impurities of a mechanical nature; a stronger heat causes it to froth, and at a red heat it burns with a white flame.

Rubbed with cold or warm water, the gum is dissolved, forming a smooth white or reddish, persistent emulsion, in which the resin and volatile oil are suspended. With rectified alcohol, which is its best menstruum, it forms a clear, yellowish-red tincture. Spirit dissolves the resin and oil, but is too feeble a solvent. Sulphuric ether dissolves the volatile oil and a portion of resin; solution of caustic potash dissolves it almost entirely, forming an emulsion when the alkali is neutralized; and solution of ammonia dissolves the gum and oil, with part of the resin. It readily unites with other resins, gum-resins, and wax; and is best preserved in bladders kept in tin boxes.

Chemical Composition.—Asafoetida contains volatile oil, resin soluble in ether, a tasteless resin insoluble in ether, various gums, sulphate of calcium, carbonate of calcium, oxide of iron, and alumina, malate of calcium, etc. The volatile oil may be obtained by distillation with water or alcohol; at first it is pale-green, but becomes yellowish-brown by age, is lighter than water, of a powerfully offensive odor, and a taste peculiar to the gum-resin; it contains sulphur (Zeise). In odor it closely resembles that of the persulphide of allyl, procured from oil of mustard. According to Schimmel & Co. (*Semi-Annual Report*, October, 1893) the gum-resin yields from 3.3 to 3.7 per cent of oil, having a specific gravity of 0.985, at 15° C. (59° F.), and an optical rotation of $-9^{\circ} 15'$; and according to Semmler's investigations (1891) it contains a terpene, probably *pinene*; also the sulphurous combinations, $C_{10}H_{14}S_2$ and $C_{11}H_{16}S_2$, and, beside other compounds, a body having the formula $(C_{10}H_{16}O)_n$. Fractionally distilled the volatile oil yields, at 300° C. (572° F.), a beautiful blue oil (*Pharmacographia*). The oil and the bitter resin are the active principles. The resin is but partially soluble in ether and is soluble in alcohol. It contains *ferulaic acid* ($C_{10}H_{16}O_4$), a substance crystallizing in iridescent, acicular crystals, having neither taste nor odor. The resin fused with alkali yields resorcin ($C_6H_4O_2$). A body named *umbelliferon* ($C_8H_6O_3$), as well as oils of various colors, may be obtained by dry distillation of the resin. Acetic, formic, malic, and valerianic acids have also been found in asafoetida. Sulphate of calcium has been found as an adulteration of this gum-resin, occurring in commercial samples sometimes to the extent of 50 per cent. The U. S. P. requirement (60 per cent soluble in alcohol) is not reached by asafoetida of commerce. Were the standard made 40 per cent, the drug would better conform to requirements (J. U. Lloyd in *Pharm. Review*, 1896).

Action, Medical Uses, and Dosage.—The odor of asafoetida is imparted to the breath, secretions, flatus, and gastric eructations. Its properties are stimulant, antispasmodic, expectorant, emmenagogue, and vermifuge (*Ed.*). Improper in inflammatory conditions of the system, but of marked value in purely functional nervous disorders, with excitability, and as a gastric stimulant in *gastro-intestinal atony*, with flatulence. It allays gastric irritation. Used in *croup*, *pertussis*, *hysteria*, *infantile convulsions*, *flatulent colic*, *chronic catarrh*, *chlorosis*, *spasmodic nervous diseases* of females, and, in combination with morphine and quinine, in *sick or nervous headache*. With resin of podophyllum and resin of cimicifuga, it is beneficial in *chorea*. Likewise efficient in *amenorrhœa* and *dysmenorrhœa*, and as an injection in *tympanitic abdomen*, *lumbricus*, and *ascarides*. In *hysteria* its effects are especially good, sometimes preventing the attack if given early, or if the disorder be already developed it tends to modify its force. In the tympanitic states of the bowels during *fevers*, or when only constipation exists, it is a prompt remedy. As an antispasmodic it holds a secondary place, probably acting best in those disorders arising from a disordered stomach. Minute doses are asserted to increase the mammary secretion. As a remedy for *bronchial cough*, dry, deep-seated and stubborn, a 2-grain pill every 3 hours will give quite positive results. Asafoetida is best adapted to cases exhibiting nervous depression, with more or less feebleness, and particularly if associated with gastric derangements with constipation, flatulence, and tardy or imperfect menstruation. Dose, in powder or pill, from 5 to 10 or 20 grains; of the tincture, from 30 drops to 2 fluid drachms. Asafoetida is also employed alone, or in combination, in the form of a suppository, or an enema.

Specific Indications and Uses.—Nervous irritation, with mental depression, headache, and dizziness; hysteroid conditions; convulsive disorders from purely functional wrongs of the stomach, gastro-intestinal irritation, with flatulence and palpitation of the heart; dry, deep, choking, bronchial cough.

ASARUM.—WILD GINGER.

The rhizome and rootlets of the *Asarum canadense*, Linné.

Nat. Ord.—Aristolochiaceæ.

COMMON NAMES: *Wild ginger*, *Indian ginger*, *Canada snakeroot*, and (improperly) *Coltsfoot*.

Botanical Source.—This American plant closely resembles the asarabacca of Europe (*A. Europæum*). It has a creeping, fleshy, somewhat jointed, yellowish rhizome, with rootlets. From it ascends a quite short stem, which is forked near the surface of the soil, and each branch bears a reniform leaf, downy on both sides, 3 or 4 inches by 3 or 5, the petiole of which is long, round, and hairy. Upon a pendulous, hairy peduncle, growing from the fork of the stem, is a solitary flower, having a very wooly calyx, consisting of 3 broad, concave, pointed leaflets, of a brownish, dull-purple or greenish color on the inside, at top and bottom, depending on the amount of light which the plant enjoys, terminated by a long, spreading, inflected point, with reflect sides. The corolla is wanting. The fruit is a coriaceous, 6-celled capsule.

Description.—Wild ginger occurs in commerce in irregularly 4-angled pieces, about 3 to 5 inches in length, and about $\frac{1}{2}$ inch in diameter. They are crooked, ash-brown, or purple-brown in color, break with a short fracture, are pulverable, and whitish internally. About every half inch exhibits nodes, to which thin rootlets are attached. The inner structure is pithy, surrounded by a broken zone of woody fibers, all enclosed in thick bark, which contains oil cells. The rootlets are traversed by a ligneous, central portion, covered with thick bark. It is fragrant, spicy, and slightly bitter.

History.—Wild ginger is a native of the United States, growing in woods and mountains, and in rich soil along roadsides, flowering in May and June. The whole herb has a fragrant odor, and a spicy, amarus taste. The root is the part used, and yields its active principles to alcohol, and partially to water by infusion. The oil is now used in the making of perfumes, and in various toilet waters.

Chemical Composition.—Asarum contains an acrid, bitter, reddish resin, a pale, spicy, aromatic, volatile oil, gum, chlorophyll, fat, starch, and various salts. It probably, also, contains an alkaloid, as Power obtained a body in very small quantities, which reacted with alkaloid-group reagents. The coloring matter (yellow), as Prof. Power has shown, appears to be the same as the *asarin* found by Graeger in asarabacca. The oil consists of *asarene* ($C_{10}H_{18}$), a neutral principle, *asarin* ($C_{12}H_{18}O_2$), *asarol* ($C_{10}H_{16}O$), and ethers of asarol—probably the acetic and valerianic—and is thought also to contain *methyl-eugenol*, a substance hitherto not observed in nature.

Action, Medical Uses, and Dosage.—*Asarum canadense* is a spicy, stimulating agent, causing perspiration, promoting expectoration, and possessing carminative properties. It may be advantageously added to tinctures and compounds to improve their flavor, and render them more stimulating. It is used in *colic* and other *painful affections* of the stomach and bowels where no inflammation exists, and in *chronic pulmonary affections*. It has been successfully used by Dr. J. R. Black in *dropsy*, with albumen in the urine. The warm infusion is an excellent agent to promote copious sweating, and may be substituted for Virginia snakeroot as a diaphoretic and in *debility*. Harsh, dry skin, with checked perspiration, in low *febrile* and *inflammatory affections*, not of the gastro-intestinal tract, and sudden *colds*, have been successfully treated with the warm infusion, which is also a prompt emmenagogue when *amenorrhœa* is due to recent colds. Dose of the powder, $\frac{1}{2}$ drachm; of the tincture, $\frac{1}{2}$ fluid drachm to 2 fluid drachms. Of the infusion (3ss to aqua Oj), freely; used also as an errhine.

Fig. 32.

*Asarum canadense*.

ASARUM EUROPÆUM.—ASARABACCA.

The rhizome and leaves of the *Asarum Europæum*, Linné.

Nat. Ord.—Aristolochiaceæ.

COMMON NAMES: *Asarabacca*, *Hazlewort*, *Wild nard*.

Botanical Source.—This plant has a creeping root or rhizome, entangled with numerous stout, branching fibers. The stems are very short, simple, round, herbaceous, pubescent, each bearing 2 dark-green, shining, reniform, obtuse, entire, somewhat downy leaves, which are opposite, 2 inches wide, on long, downy, foot-stalks; also, 1 drooping flower, not an inch long, fleshy, of a dusky-purple color, placed upon a short terminal peduncle. The calyx is campanulate, greenish at the base, divided into 3-pointed, purplish segments, which are erect and turned inward at their extremity. The corolla wanting. The fruit is a 6-celled, coriaceous capsule, crowned with the persistent calyx.

Description and History.—The root is ash-colored, 2 or 3 lines in thickness, 4-angled, contorted, rough; has a pepper-like odor, a biting, spicy taste, and yields an ash-colored powder. Its properties are taken up by water or alcohol; boiling evaporates and age impairs them. The leaves have virtues similar to those of the root; they have a very feeble odor, a taste like that of the root, with some bitterness, and produce a green powder, having a yellow tinge. *Asarabacca* is a European plant, growing in moist, hilly woods, and presenting a single, bell-shaped, dingy-brownish-red flower from May to August. The root and leaves are used in medicine, and when recent are quite acrid. They should always be carefully dried for preservation.

Chemical Composition.—Græger has found in the root volatile oil, *asarum camphor* ($C_{10}H_{16}O_2$) (*asaron*), *asarit*, *asarin*, tannic acid, resin, starch, extractive, gluten, albumen, various salts, etc.; in the herb, *asarin*, tannic acid, extractive, citric acid, chlorophyll, etc. (P.). The substances designated by Græger as *asarum camphor* and *asarit*, were subsequently shown to be identical in chemical composition, differing only in their physical properties, the former being at first an oily liquid, which afterwards crystallizes in scale or needles from an aqueous distillate, and the latter acicular crystals, precipitated from the same. *Asarin*, a yellow body, gives to this drug its bitterness. It is probably identical with the *cytisin* of Lassaigne and Fenuelle. The yield of oil is about 1.0 per cent. It has an odor resembling valerian, is yellow, viscid, and has a pungent, burning taste. According to Schimmel & Co. (*Semi-Annual Report*, October, 1893), its specific gravity, at 15° C. (59° F.), ranges from 1.046 to 1.068, and its known constituents are *asarone*, *pinene*, and *eugenol-methyl-ether*. The chemistry of *asarone* was investigated in detail by Rizza and Butlerow, in 1884 and 1888.

Action, Medical Uses, and Dosage.—*Asarabacca* produces nasal irritation, followed by free secretions, which flow persistently. It is emetic, cathartic, and errhine. Used principally as an errhine in certain affections of the brain, eyes, face, and throat, *toothache*, *ophthalmia*, and *paralysis of the mouth and tongue*. Internally it is a stimulant in doses of 10 or 12 grains; and an emetic in $\frac{1}{2}$ drachm or 1 drachm doses. It is said to be used in France by drunkards to produce vomiting.

Related Species.—*Asarum Sieboldii*, Miquel. This plant is the *to-sai-shin* of the Japanese. The rhizome is slender, stem-scarred, and has attached to it thick, tufty aggregations of long, light-brown rootlets. These are white and mealy internally, surrounding a yellow, woody cord. It has an aromatic fragrance, and the taste resembles the combined flavors of *sassafras* and *nutmegs*, followed by an irritating pungency. It grows in Japan.

ASCLEPIAS (U. S. P.)—ASOLEPIAS.

The root of *Asclepias tuberosa*, Linné"—(U. S. P.).

Nat. Ord.—Asclepiadææ.

COMMON NAMES: *Pleurisy root*, *Butterfly weed*, *Orange swallowwort*, *Wind root*, *Tuber root*.

ILLUSTRATIONS: Bigelow, *Am. Med. Bot.* II, 59; Barton, *Med. Bot.* I, 239.

Botanical Source.—*Asclepias* has a perennial, large, fleshy, branching, white, and sometimes fusiform-like root, from which numerous stems arise, growing from 1 to 3 feet high; these are erect, or more or less procumbent, round, hairy, green or red, growing in bunches from the root. The leaves are alternate, the lower ones pedunculated, the upper sessile. They vary from linear to oblong-lanceolate, are hairy, dark-green above, paler beneath, waved on the edge, and in the old plants sometimes revolute. The flowers are numerous, erect, of a beautifully bright orange color, and are arranged in terminal, rarely axillary, umbels, which are corymbose.

History.—Many of the asclepiadeæ have, from time to time, furnished the medical profession with important medicines. The order is largely represented in the tropics, but the North American genera are comparatively few. The most important plant bearing the name *asclepias* (derived from *Æsculapius*), to Eclectics at least, is the *Asclepias tuberosa*, or butterfly weed. It is perhaps best known to the profession, at least to the older physicians, as *pleurisy root*, a name indicating one of its most important applications. Though growing most abundantly in the South, it may be found as far north as Massachusetts, preferring gravelly and sandy soils. It blooms in June, July, and August, and when in flower forms one of the most conspicuous and handsomest features of a summer landscape. For miles along the railways clusters of the rich, deep orange flowers of the butterfly weed, as it is called, bedeck the fields, a sight perhaps more pleasant because it blooms when the majority of showy plants are less abundant. This plant differs from its congeners in being destitute of the milky juice common to most of them, such as the common milkweed (*Asclepias Cornuti*), and others. Several popular names have been given it, indicative either of its appearance or use, the most common of which are pleurisy root, butterfly weed, orange swallow-wort, silkweed, tuber root, wind root, white root, flux root, and Canada root. The official part is the root; it is spindle-shaped, of a light-brownish color on the outer surface, white, coarse, and striped within. When fresh it has a disagreeable, slightly acrimonic taste; when dried its taste is slightly bitter. Boiling water or alcohol extracts its virtues. The infusion is undoubtedly the most effective medicinal preparation. When the infusion can not be employed specific *asclepias* is next preferred.

Description.—"Root large and fusiform, dried in longitudinal or transverse sections, from 2 to 15 Cc. long ($\frac{1}{2}$ to 6 inches), and about 2 Cc. ($\frac{1}{2}$ inch) or more in thickness; the head knotty, and slightly but distinctly annulate, the remainder longitudinally wrinkled, externally orange-brown, internally whitish; tough, and having an uneven fracture; bark thin, and in two distinct layers, the inner one whitish; wood yellowish, with large, white, medullary rays. It is inodorous, and has a bitterish, somewhat acrid taste. When long kept it acquires a gray color"—(*U. S. P.*).

Chemical Composition.—Mr. Elam Rhoads found in this root gum, pectin, starch, albumen, gallic and gullo-tannic acids, lignin, salts, an odorous material of a fatty nature, two resinous bodies—one dissolving in ether, the other refusing to so dissolve—and a fixed oil. Mr. Rhoads also obtained a peculiar body having the taste of the drug, which may be thrown down from a strong infusion of the root by tannin. By decomposing with litharge and exhausting with boiling alcohol, decolorizing and evaporating the liquid, a yellowish-white powder is obtained, which is soluble in ether, alcohol, and less freely in water, from which it may be dissociated by tannin. Sulphuric acid colors it brown and nitric acid pink, finally becoming purple (Clabaugh). The above-mentioned principle was ascertained by Quackenbush (1889) to be a glucoside, and was obtained by

Fig. 33.

*Asclepias tuberosa.*

him in crystalline condition. He also detected a fluorescent body, but no tannin.

Action, Medical Uses, and Dosage.—Asclepias, or pleurisy root, was one of the most common of the indigenous medicines employed by the Eclectic fathers.

Fig. 34.

Fresh root of asclepias.

It was favorably written upon by most of the earlier writers on American medicinal plants. The drug has fallen into unmerited neglect, and could profitably be employed at the present day for purposes for which much more powerful, and sometimes dangerous, drugs are used. It has an extensive range of usefulness, being possessed of diaphoretic, diuretic, laxative, tonic, carminative, expectorant, and probably antispasmodic properties. Asclepias and coralorrhiza, are, *par excellence*, the diaphoretics of the Eclectic materia medica.

Like *crawley*, it is not stimulating, and may be used to promote diaphoresis, no matter how high the degree of fever. It differs from most diaphoretics in producing a true secretion from the skin that more nearly resembles the normal function of insensible perspiration than any other agent of its class. It increases largely the elimination of solid material to the exclusion of copious perspiration. *Crawley* increases both the solid and liquid transpiration. Asclepias may be indicated even though the patient be freely perspiring. While the liquid flow is copious it may be deficient in power to carry off the solid detritus, an act which the asclepias will perform, provided the indications for its use are present. While it is serviceable even where the temperature is high, it does its best work where the temperature is but moderately exalted, and when the skin is slightly moist, or inclined to moisture, and where the pulse is vibratile and not too rapid. If the pulse be rapid, weak, and small aconite will assist it; if rapidly bounding and strong, veratrum should be administered at the same time. Pleurisy root has a deservedly good reputation in respiratory diseases. It acts upon the mucous membrane of the pulmonary tract, augmenting the secretions and favoring easy expectoration. Besides its action on the respiratory mucous surfaces its action upon the skin as a true diaphoretic, establishing the insensible perspiration when the skin is dry and harsh, and correcting that weakness of the skin which allows the sweat to pour out too freely, renders it of value in the *colliquative sweating of phthisis*. As its popular name indicates, pleurisy root is of much value in treating *pleuritis*. Here it will greatly assist the action of *bryonia* and *aconite*, the latter being administered in the early stage, and *bryonia* and *asclepias* in alternation later. Not only is its action on serous membranes marked, as in the preceding disorder and in *pleurodynia*, but it is very effectual in *intercostal neuralgia* and *rheumatism*, as well as in *pericardial pains*. The chief action of asclepias is to lessen arterial tension, and acute diseases are those in which it is of most value. With the indicated sedative it is one of the best known agents in the early stage of *pneumonia* and *pleuro-pneumonia*, provided always the indications alluded to are present. Some cases will yield to asclepias alone, but this is not generally the case, as the drug plays more the rôle of an assistant than a leading remedy. It is a safe drug, for while it may not act as efficiently when not indicated, it may be said to never be contraindicated, so far as expecting any harm from its use is concerned. Hyperemic states of the breathing organs seem to call for asclepias. In *pneumonia*, as well as in *bronchitis*, it is best adapted to the acute stage, where the lesion seems to be extensive, taking in a large area of lung parenchyma and mucous tissues. Webster believes it best adapted to control vascular disturbances in the area supplied by the bronchial arteries, and suggests that by reserving it for this place we shall lessen its liability to confusion with other appropriate remedies. It undoubtedly acts upon the general circulatory apparatus, lowering arterial tension. In the convalescing stage of pneumonia, and other respiratory lesions, when suppression of the expectoration and dyspnoea threaten, small doses at frequent intervals will correct the trouble. In *dry asthma* with fever, but lack-

ing the spasmodic element, 5-drop doses of specific *asclepias* will do good service. As a remedy for dry and constricted *cough* it may be given in small amounts, preceded a half hour by specific *lobelia* in doses of 1 or 2 drops. In *catarrhal troubles* specific *asclepias*, well diluted, is useful as a local remedy when used early in the disease. It, as well as *euphrasia* and *matricaria* (*chamomilla*), is among our best drugs for snuffles, or *acute nasal catarrh of infants*. In *phthisis* it is valuable to alleviate the distressing cough and to allay irritability of the mucous surfaces, and is not without good effects on the circulation and the stomach, through its subtonic action. It is an excellent remedy for ordinary *colds*. It is, in fact, one of our best drugs for catarrhal conditions, whether of the pulmonary or gastro-intestinal tract, especially when produced by recent colds.

Stomach troubles, particularly those of children, are often markedly benefited by small doses of specific *asclepias*. A weakened stomach, accompanied with nervous impairment, or with catarrhal complications, rendering digestion difficult and painful, is often toned to do its work pleasantly under the use of small doses of *asclepias*. *Diarrhœa* and *dysentery*, when of catarrhal character and due to cold, are benefited by alternating with other indicated remedies, from 10 to 15 drops of specific *asclepias*, or the infusion may be freely employed. As a remedy for gastric disorders it is well adapted to children and weak individuals. *Headache* from disordered digestion has been cured with it, and for *flatulent colic* in young children: R Specific *asclepias*, gtt. x to xv; aqua, fl̄iv. Mix. Teaspoonful every 5 minutes. *Dioscorea* may also be administered with it in cases of flatus in adults and children. A pill composed of equal parts of alcoholic extracts of *asclepias*, *alertris*, and *dioscorea* will be found very beneficial in *flatulency*, *borborygmi*, and where persons are subject to *flatulent* and *bilious colic*. In some cases, especially of long standing, the addition of pulverized African ginger will much improve its efficacy. *Asclepias* is a remedy for *nervous irritability* of children, especially when due to gastric disturbances. The dry forms of *cutaneous affections* are benefited by it, especially where it is necessary to establish the true dermal secretions. It is likewise beneficial in this sense in those cases of *neuralgia* and *acute rheumatism*, accompanied with profuse sweating. It alters the character of the perspiration. In the *exanthematous fevers* it favors the eruptive process, and in *painful inflammations* gives some relief by its diaphoretic action. *Asclepias* has been used in *dropsy*, but we have better agents for that affection. It is not an active agent, yet on the whole, though apparently a feeble remedy, when indicated, it accomplishes a purpose which no other remedy in the *materia medica* fulfils. Dose of the powder, 20 grains to 1 drachm, 3 or 4 times a day; of a strong infusion (the best preparation), from 2 to 4 fluid ounces, 4 or 5 times a day, until perspiration is produced; specific *asclepias*, 1 to 60 drops; fluid extract, 1 to 60 drops.

Asclepidin, or *oleo-resin of asclepias*, is a dark, semi-liquid mass, and is prepared by evaporation or distillation of the saturated tincture in water, similar to the plan pursued for obtaining resin of *cimicifuga*. It was formerly used for all purposes to which the crude article is applied, in doses of from 1 to 5 grains, 3 or 4 times a day, or as indicated.

Specific Indications and Uses.—The specific indications for *asclepias*, according to Dr. J. M. Scudder are: "Pulse strong, vibratile; skin moist, pain acute, and seemingly dependent on motion." The skin may be hot and dry or inclined to moisture; the urine is scanty; the face flushed; vascular excitement is marked in the parts supplied by the bronchial arterioles; inflammation of serous tissues; gastro-intestinal. catarrhal troubles due to recent colds.

ASCLEPIAS CORNUTI.—MILKWEED.

The root of the *Asclepias Cornuti*, Decaisne (*Asclepias syriaca*, Linné).

Nat. Ord.—Asclepiadææ.

COMMON NAMES: Common milkweed, Silkweed, Wild cotton.

Botanical Source.—The common milkweed has a large, stout, simple, somewhat branched stem, growing from 2 to 5 feet high. Its leaves are ovate-elliptical, spreading, opposite, with short but distinct petioles, gradually acute, tomentose beneath. The flowers are fragrant, arranged in several axillary, subterminal,

nodding, dense, globose umbels, each of 20 or more flowers. The calyx segments are lanceolate. The corolla is pale or greenish-purple, reflexed, leaving the corona, which is of nearly the same hue, quite conspicuous. But few of the flowers prove fertile, producing oblong-pointed pods or follicles covered with sharp prickles, which contain a mass of long, silky fibers with seeds attached, and which fibers have been used for beds, pillows, and in the place of fur in manufacturing hats.

Description.—This rhizome grows from 1 to 6 feet in length, and is cut into transverse pieces or slices about $\frac{1}{2}$ inch or $\frac{3}{4}$ inch in diameter. The root is cylindrical, finely corrugated, tough, has a somewhat knotty appearance from stem-scars, or partially formed branches, and breaks with a short, splintered fracture. Externally it is grayish-brown; internally white. Its white bark is thick and surrounds a yellowish, porous, woody center, and contains lactiferous channels. It has scarcely any odor, but its taste is disagreeably bitter.

History and Chemical Composition.—This herb is indigenous to the United States, inhabiting rich soils, uncultivated fields, roadsides, etc., and bearing whitish-purple, or rather dull, pinkish-purple flowers from June to September. When wounded it emits a milky fluid, which contains water, wax-like fatty matter, gum, caoutchouc, sugar, various salts, etc. A crystalline, resinous substance, has been obtained from the juice of the *A. Cornuti*, to which the name of *asclepion* has been given. It is procured by boiling and then filtering the juice, and separating the *asclepion* from the filtrate by ether, from which it may be subsequently obtained by evaporation, and purified by several washings with pure ether. *Asclepion* thus obtained is a crystalline solid, without taste or smell, and is readily dissolved by spirits of turpentine, pure acetic acid, and sulphuric ether (C. List, 1849).

Tannin, gummy material, ash, and a small quantity of volatile oil were found in the root by Mr. W. L. Hinchman, in 1881, who also obtained, in an impure state, a bitter principle. A volatile principle of an acrid character is said to reside in the fresh root. Quackenbush obtained a crystalline glucoside similar to that which he obtained from pleurisy root, but failed to find tannin (*Amer. Jour. Pharm.*, 1889). Starch is present in the parenchymatous portion of the root.

Action, Medical Uses, and Dosage.—The root of this plant is tonic, diuretic, alterative, emmenagogue, purgative, and emetic; and given in large doses it is stimulant and anthelmintic. Dr. Richardson has attributed anodyne properties to it, but he must have had reference to some other plant. It has, however, recently been revived as a remedy for *muscular rheumatism*, some claiming it to be as effective as *macrotys*. It should be studied in this connection. It has been found useful in *amenorrhœa*, *dropsy*, *retention of urine*, *asthma*, *dyspepsia*, *cough*, *dyspnœa*, *constipation*, *primary syphilitic disease*, *worms*, *scrofulous* and *rheumatic disorders*. The action of the heart is augmented under its use. A very excellent fluid extract may be made from it as follows: To 16 troy ounces of the recently dried root, finely bruised, add 6 fluid ounces of ether and 4 fluid ounces of alcohol; form a tincture by slow percolation, and set it aside. Then thoroughly exhaust the root by percolation, with 6 fluid ounces of alcohol and a sufficient quantity of water; evaporate this last over a water-bath, add the first tincture, made with ether and alcohol, to it, and reduce by evaporation to 1 pint. An aromatic, bitter, red fluid extract is thus obtained, of which 1 fluid drachm is equal to 1 troy ounce of the crude root. The dose is from 10 drops to 1 fluid drachm; it may be taken in ginger syrup, lemon syrup, cinnamon water, or other pleasant vehicle, to cover its unpleasant taste. Dose of the powder, 10 to 20 grains; of the decoction, 2 to 4 fluid ounces; of the tincture, 10 to 60 minims.

ASOLEPIAS INCARNATA.—FLESH-COLORED ASCLEPIAS.

The root of the *Asclepias incarnata*, Linné.

Nat. Ord.—Asclepiadææ.

COMMON NAMES: *Flesh-colored asclepias*, *Swamp milkweed*, *Swamp silkweed*, *Rose-colored silkweed*, *White Indian hemp*.

Botanical Source.—Swamp milkweed has a smooth, erect stem, with 2 downy lines above and on the branches and peduncles, branching above, about 3

or 4 feet high. The leaves are opposite, oblong-lanceolate, acute, or pointed, obtuse at the base, on short petioles, and slightly tomentose. The flowers, which are red or reddish-purple and sweet-scented, are disposed in numerous umbels, which are crowded, erect, mostly terminal, and often in opposite pairs. The hoods of the crown are entire; the horns exserted and subulate. The leaves are from 4 to 7 inches long, and from $\frac{1}{2}$ inch to $1\frac{1}{2}$ inches wide; the umbels are from 2 to 6, on a peduncle 2 inches long, and consist of from 10 to 20 small flowers. There is a variety of this plant, the *Asclepias incarnata* var. *pulchra*, which is more hairy, with broader and shorter petioled leaves.

History.—This herb inhabits damp and wet grounds throughout the United States, and bears red flowers in July and August. On wounding the plant a milky juice exudes. The part used is the root; it varies in thickness from 1 to 6 lines, and is of a light-yellowish or brownish color. It imparts its properties to water.

Description.—The root is about $\frac{3}{4}$ to $\frac{1}{2}$ inch long, oblong, or unsymmetrically globular, hard, knotty, and has attached to it several rootlets 3 to 5 or more inches long. Externally the color is yellow-brown; internally nearly white. The bark is thin, surrounding a wood that is tough and white and has a thick pith. The rootlets are of a pale-brown color and composed about equally of a woody center and whitish bark. The root is nearly without odor and has a sweet, harsh, and finally amarous taste.

Chemical Composition.—The root contains starch, pectin, grape-sugar, albumen, a fixed and a volatile oil, the latter in small amount, two resins of an acrid character (J. Y. Taylor), and an unstable, amorphous, yellow glucoside, *asclepiadin*, whose physiological effects are similar to those of emetine (Gram, *Archiv. f. Exper. Path. und Pharm.* 19, page 389).

Action, Medical Uses, and Dosage.—Anthelmintic, for which purpose the powder may be used in doses of 10 to 20 grains, 3 times a day; or the decoction, 2 to 4 fluid ounces. It has been recommended in *rheumatic, asthmatic, catarrhal, and syphilitic affections*, and as a vermifuge. Said to produce vomiting and purging, but this is doubtful. It is undoubtedly a valuable agent, and worthy of further investigation. According to Frazer (*Birmingham Med. Review*, 1884) this agent is stomachic and a quick, powerful, and reliable diuretic. It acts upon the heart and circulatory system like foxglove, but without its gastro-intestinal disturbances. It is useful in *chronic mucous disease of the stomach* and in *erysipelatous affections*. The dose of the fluid extract, 15 to 60 minims; infusion (3ss to aqua Oj), $\frac{1}{2}$ to 1 fluid ounce; specific *asclepias incarnata*, 1 to 10 minims.

Specific Indications and Uses.—Chronic mucous diseases of the stomach; catarrhal discharges; leucorrhœa; entozoic affections.

Related Species.—*Asclepias curassavica*, Linné. Habitat: Central America, South America, and West Indies. *Bastard ipecacuanha*, known also in Central America as *ponchishuis* and *cancerillo*. It is also called *Bloodweed* and *Red head*. It is a perennial herb, with red (rarely white) flowers, and its smooth, shining seed-hairs are sometimes called *Vegetable silk*. This herb yields *asclepiadin*, a glucoside soluble in alcohol, but scarcely dissolving in ether, yielding to the latter *asclepin*, a derivative of the former. Among the effects of this drug Guimerais (1881) found it to impress the cardiac muscles and to dilate the larger arteries. Large doses (root 20 to 40 grains) are emetic; smaller doses are cathartic and anthelmintic.

Calotropis gigantea, R. Brown (*Asclepias gigantea*, Willdenow). Habitat: East Indies and South India; and *Calotropis procera*, R. Brown (*Calotropis Hamiltonii*, Wight) North India, West Asia, and Africa. Shrubs yielding *Mudar-bark*, which contains a bitter principle, an acrid, resinous body, and starch, caoutchouc, and resins. A crystalline body resembling *asclepin* was found in it by Waddell. The bark has a bitter, acrid, mucilaginous taste.

Mudar-bark (3 or 4 grains) is used as an alterative and tonic in India; in larger doses (20 to 40 grains) it is emetic and diaphoretic, increasing the action of the surface capillaries and absorbents. It is employed as a substitute for ipecac in *dysentery*; also in *leprosy, elephantiasis, rheumatism, dropsy, and syphilis*. Dose, 3 to 12 grains, 3 times a day. The dry juice is said to be used in India as an abortifacient and to destroy female babies.

Cynanchum Vincetoxicum, Persoon (*Vincetoxicum officinale*, Moench; *Asclepias Vincetoxicum*, Linné). Europe, where it is known as *White swallow-wort*. The root is employed, and when fresh has a valerian-like odor, which is practically dissipated on drying. It contains fat, essential oil, pectin, and *asclepin*, a resinous body shown by Gram to be a derivative of *asclepiadin*, the emetic glucoside. It is thought to be identical with the *vincetoxin* of Tanret. The bark has an acrid, sweet, and bitterish taste. Emetic, and in large amounts may induce fatal gastric inflammation. *Scrofulous and cutaneous disorders* have been treated with it.

ASEPSIN.—ASEPSIN.

The trade-name of a compound prepared from wintergreen oil.

FORMULA: $C_7H_5O_2Na$. MOLECULAR WEIGHT: 150.64.

History, Preparation, and Description.—Asepsin, so named by Prof. A. J. Howe as a trade-mark name, is a compound made of oil of wintergreen (*Oleum Gaultheriæ*), and introduced as a remedy under the above trade-name. This substance is a definite sodium compound of the above composition. It is a white, crystalline powder, nearly insoluble in cold alcohol, chloroform, and ether, but soluble in boiling alcohol and ether. It is perfectly and readily soluble in both cold and hot water. Asepsin has a sharp, sweetish taste, and the agreeable odor and flavor of oil of wintergreen. It has an alkaline reaction, and nearly all acids decompose it, producing wintergreen oil.

Action, Medical Uses, and Dosage.—Asepsin is one of the most important of the more recent introductions into medicine, and in the Eclectic school is the most extensively-employed agent for antiseptic purposes where putridity is to be overcome. Applied to the skin in solutions of greater or lesser density it imparts to the surface a sensation of slipperiness. If the skin be unbroken a sensation of warmth is very quickly produced by even a 10 per cent solution. Stronger solutions slightly redden the skin and impart a feeling of stiffness. Applied to the mucous tissues it acts energetically. It slightly liquefies albumen, differing thereby from carbolic and salicylic acids in not causing coagulation and consequent hardening of the tissues.

Taken internally asepsin imparts a feeling of warmth, and in doses of a grain or upwards causes an appreciable rise in the body temperature, and quickens respiratory action. The renal and cutaneous functions are also augmented by it. Large doses cause intense burning in the stomach, with dryness of the fauces, and these sensations may extend to the rectum after an evacuation. It does not appear to be readily absorbed, as most of it, as shown by its odor, passes through the bowels as methyl salicylate. However, small doses, well triturated with starch or milk sugar appear to be taken up by the blood, and may be detected in the urine by the test for salicylic acid, the odor of wintergreen, however, persisting. Pepsin, pancreatin, and other similar ferments are not affected by asepsin. On the contrary, minute doses encourage digestion.

Asepsin possesses decided antiputrefactive and antifermentative properties. When fermentation and putrefaction are brought about by the presence of formed ferments they are promptly arrested by the exhibition of asepsin. The remarkable preservative power of asepsin was well illustrated in the experiments conducted by Prof. Lyman Watkins, M. D. Comparative tests were made with distilled water, mercuric chloride solution, and solution of asepsin. Fish, beef, and mutton were immersed in these solutions, and kept in moderately warm situations. The preservative power of the asepsin solution proved greater than that of the others, the flesh being preserved about three times as long as by the bichloride solution (1 to 20,000). Not only did the asepsin retard decomposition, but checked the decomposition already proceeding in a piece of the flesh removed from one of the other solutions. Neither did it attack the flesh, which showed no change under the microscope, whereas that subjected to the action of corrosive sublimate exhibited a white film of coagulated albumen. It effectually checks alcoholic fermentation in cider (see below).

Therapeutically asepsin is an agent of great value. Internally exhibited it acts as a corrector and preventer of fermentation and putrefaction. Many have employed it in small doses as an intestinal antiseptic in *cholera infantum*, *dysentery*, and *typhoid fever*. The dose, however, should be but a fraction of a grain, lest an increase of temperature be provoked. Asepsin is exceedingly useful in *flatulent conditions* of the stomach and bowels. In minute doses it favors digestion, and may be employed where digestion is sluggish and the meal is followed by offensive ructus. In *gastro-intestinal disorders* it acts best after excessive acidity has been first modified by the indicated alkali. Though alkaline itself it is often insufficient to entirely overcome such conditions, hence its association with the carbon-

ates, as magnesia, and particularly with sodium bicarbonate. Fearn recommends a combination of the latter character prepared as follows: R Asepsin, grs. v to xv; sodium bicarbonate, ʒi. Triturate well. Dose, 1 to 3 grains. This, like asepsin alone, is indicated by the clean, white tongue, with pallor of the membranes, gastric fermentation, and flatulence and atony, associated with gaseous distension of the abdomen. A dusky coloration of the membranes also indicates asepsin. In *dyspeptic disorders*, Prof. McMillan associates with it pepsin or hydrastis, as indicated; it may also be combined with papoid, ingluvin, nux vomica, etc., and similar digestive ferments and tonics. When a cadaverous fetor contaminates the breath, we have added to its solution potassium chlorate; and with a dirty, pasty tongue, with a mawkish, unpleasant odor short of cadaveric, sodium sulphite. In many of the disorders in which asepsin may be exhibited internally it may be added to the solutions of other medicines, serving at the same time to prevent them from decomposition, especially in hot weather. Thus it may be given with nux vomica, hydrastis (with Lloyd's hydrastis it forms a precipitate), etc.; combined with resinous alcoholic preparations, such as podophyllum, macrotys, etc., it serves to make better mixtures, and seemingly renders them more efficient. This is particularly true of macrotys in *rheumatism*, the asepsin, like other methyl salicylates, undoubtedly possessing antirheumatic qualities. It must be remembered, however, that asepsin, on account of its strong alkalinity, should not be added to solutions containing considerable amounts of toxic alkaloids, as belladonna, aconite, gelsemium, etc., lest, by precipitation of these bases, the patient's life be endangered by getting a large dose of the deposited alkaloids when the last doses of medicine in the glass or bottle are administered. *Stomachic* and *intestinal dyspepsia* of catarrhal forms are benefited by asepsin, and it is one of the best agents to control that unpleasant rolling of gases in the bowels (*borborygmus*) so annoying to women. Asepsin may be administered in *gastric cancer* to overcome the stench; it is also useful in *gastric ulcer*. *Diarrhoea*, with fetid evacuations, is benefited by asepsin. Asepsin has also been used internally in *scarlatina* and *diphtheria*, chiefly for its stimulating and disinfecting action. Asepsin appears to be capable of restraining *passive hemorrhage*. Prof. R. L. Thomas (*Ec. Med. Jour.*, 1888, p. 71) reports a case of severe and alarming hemorrhage from a uterine fibroid, from which the patient was gradually becoming anemic and dropsical. Six weeks' treatment with R Asepsin, grs. x; aqua flʒiv; mix; teaspoonful every ½ or 1 hour during the hemorrhage, and 4 times a day during the interval, cured the patient.

As a local antiseptic asepsin has had a more extended use in the Eclectic school than any other topical agent of this class. Very dilute solutions act as a pleasant cleansing agent; solutions of 20 per cent or higher are mildly caustic, but do not leave a scar nor dry the secretions. *Wounds treated with asepsin or asepsin in hamamelis* heal kindly. Applied to *cancerous growths* its deodorant effects are remarkable. Applied to an extensive and foul cancer after death it removed the odor so effectually that no stench could be observed at the time of burial three days later. It is useful to assist in curing and in removing fetor from foul and intractable *scrofulous ulcers* and *buboes*; *offensive armpits* and *fetid feet* are deodorized by it. Applied to *burns* it controls the pain and promotes healing, with less tendency to cicatrization than by other forms of treatment. A cerate or ointment of it may be applied, having previously well-washed the parts with a moderately-strong solution of asepsin in water. An elegant dressing for *burns*, *scalds*, *cuts*, *abrasions*, *lacerations*, and *contusions* consists of a solution of 5 to 10 grains of asepsin in 1 fluid ounce of distilled hamamelis. In all *surgical operations* asepsin may be used in solution as a wash and applied in trituration, or solution as a dressing. Dr. A. P. Taylor employs a solution of 3 grains of asepsin to 1 ounce of water to wash out *thoracic abscesses*. Many *skin affections* requiring alkaline medication and strict cleanliness may be treated with a solution or ointment of asepsin. It is especially useful in *rhus poisoning*, *porrigo*, *chronic eczema*, and *crusta lactea*. A solution of asepsin, or combined with hamamelis, sodium sulphite, or potassium chlorate, is very effectual in the *angina of scarlatina*, and assists in removing the false membrane of *diphtheria*. *Vegetative growths* may be removed with a 20 per cent solution of asepsin. Cloths wetted with asepsin solution (7½ grains to aqua Oj) and applied to the breasts may abort *mammary abscess*, when irritable and chapped

nipples are a complication. Mixed with egg albumen it also forms a good application to *sore nipples*. To cure foul, indolent *tibial ulcers* Prof. John Fearn recommends the addition of 5 grains of asepsin to 1 ounce of ointment of *Umbellularia californica* (leaves, 8 ounces; petrolatum, 1 pound; cook until crisp, and strain), the parts having first been washed with a solution of asepsin. An ointment of asepsin has given excellent results in *pruritis ani*. Triturated with an equal amount of bismuth subnitrate and applied locally (associating with this the internal administration of apis, podophyllum, and hamamelis), it has cured a long-standing case of *piles* (Dr. W. P. Best, *Ec. Med. Jour.*, 1894).

Asepsin has a wide application in *gynecological and obstetrical practice*. For foul-smelling, acrid *leucorrhœa* a wash of asepsin forms an effectual treatment, and more especially if combined with borax. As a cleansing and deodorant application after *labor* it has no superior. An injection of hot asepsinated water, with or without the addition of borax or potassium chlorate, does excellent service in cleansing the parts of the foul discharges due to fragments of *retained placenta*, the womb being first curetted, and in removing offensive *lochial accumulations*. It has thus rendered excellent service after the birth of dead and decayed fetuses. *Gonorrhœa* in the female, as well as in the male, is well treated by a small portion of asepsin ($\frac{1}{4}$ grain) in about 4 fluid ounces of warm water or liquid alboline.

Asepsin is extensively employed in the treatment of *catarrhal disorders* of the nose and naso-parynx. Its agreeable odor, stimulant effects, and cleansing powers make it particularly desirable for this purpose. It may be used alone or in combination with other agents, generally in solution, in water, liquid alboline, or colorless hydrastis, as a douche or spray. It is particularly adapted to *ozena*. An ointment is sometimes used in mild cases. It is one of the few agents that gives decided relief in *periodical hyperæsthetic rhinitis* or *hay fever*. For this purpose the following ointment may be used to relieve the distressing irritation and consequent sneezing: R Asepsin, grs. vj; cocaine hydrochlorate, grs. j; petrolatum, \mathfrak{z} i. Mix. Sig. Apply to mucous membrane of the nose as needed. A solution of menthol and asepsin in liquid alboline is also effectual in this disorder.

A solution of asepsin is very useful as an ordinary gargle and mouth-wash to cleanse the parts of *foul accumulations*. For this purpose it is often desirable in *typhoid* and other *fevers*, and particularly for the insane, who are prone to allow particles of food to accumulate upon the teeth, which give rise to dental caries and offensive breath. Combined with chalk, orris-root, or charcoal it forms a useful dentifrice. F. I. Sumner, D. D. S. (paper before *Twenty-seventh Annual Meeting of Sixth District Dental Society of New York*), recommends solution of asepsin for *syrringing cavities* previous to treatment or filling. For removing *stains* from the enamel he employs the following with which to apply powdered pumice to the teeth: R Asepsin, \mathfrak{z} i; alcohol, \mathfrak{z} iv; glycerin, \mathfrak{z} xij. Mix by agitation. He also advises the foregoing *Liquid Asepsin* as preferable to other antiseptics, being non-injurious to the metallic surfaces, for disinfecting instruments and mouth-mirrors; the glycerin, by leaving a transparent film on the glass, also serves to prevent clouding of the mirror by the patient's breath. Sprinkling a little asepsin in the water before preparing plaster for impressions is also advised to modify the unpleasant flavor of the mass; *putrescent dental pulp* may be treated with asepsin, and kneaded with gutta-percha it may be utilized for root-filling. Its pleasant odor and flavor, and its freedom from poisonous and corrosive qualities, make it one of the best of antiseptics for dental operations.

Asepsin may be used in place of the more dangerous antiseptics in *ocular surgery*. For this purpose 1 grain of asepsin to 1 fluid ounce of distilled water is a desirable strength. It prevents purulent complications and keeps the traumatic surfaces in a healthy condition. The commoner local medicines (silver nitrate excepted) employed in ocular therapeutics may be dissolved in the above solution. It will prevent a sediment forming in cocaine solutions (W. P. Biles, *Ec. Med. Journ.*, 1896, p. 504). *Conjunctival inflammations*, and particularly *catarrhal* and *purulent forms of conjunctivitis*, are benefited by cleansing washes of asepsinated water.

Asepsin, as pointed out by Dr. Albert Saylor, is an excellent preservative of cider. The following mixture is advised for a barrel of cider (45 gallons). Take

of strong alcohol 10 fluid ounces; oil of sassafras, $\frac{1}{2}$ fluid ounce; asepsin, $\frac{3}{4}$ ounce. Mix in a bottle in the order named. If the cider be clear of pomace add at once; if not clear allow it to stand a day before adding the preservative. Such a cider Dr. Sayler advises in doses of 2 glasses a day in persons inclined to *muscular* and *arthritic rheumatism*, which treatment he claims is effectual as a preventative of these disorders.

The dose of asepsin for internal use ranges from a fraction of a grain to $\frac{1}{4}$, and rarely 1 grain. As a local application solutions varying from 1 to 20 per cent may be employed as circumstances warrant; ointments and liquid albolene solutions may be used of similar strengths. Of the compound powder of asepsin (grs. x to xv) and sodium bicarbonate (3i) the dose may range from 1 to 20 grains. A SOLUTION OF BORATED ASEPSIN, advised for internal and external use, is prepared by Prof. Fearn as follows: Take of asepsin, 3i; glycerin, fl3ii; sodii boras, 3i; aqua destillata, fl3vi. Place the asepsin in a mortar, and little by little add the glycerin, triturating until well mixed. Make a solution of the borax and distilled water, and lastly mix the two solutions by agitation. Besides the uses above mentioned this solution may be used as a spray or wash for *purulent conjunctivitis* and as a wash for *bladder affections*.

Specific Indications and Uses.—Fermentation and putrefaction; pale tongue, or dusky discoloration of throat and tongue; fermentative dyspepsia, with atony, flatulence, and colicky pain; abdominal tympanites; borborygmus, prune-juice evacuations; feeble capillary circulation, with tendency to breaking down of tissues; rhus poisoning, ulcerations, etc. A general antiseptic for surgical, gynecological, and obstetrical manipulations.

Preparations.—ASEPTANILIDE. Dr. B. K. Jones, of Kenton, Ohio, has formulated a combination of asepsin (5 grains) and acetanilid (1 ounce), which he regards as an excellent remedy for various forms of *headache*, and especially those characterized by sharp, lancinating pains. If taken early, before the stage of nausea ensues, it will abort *sick headache* and *sea-sickness*. Externally employed Dr. Jones declares it an admirable dry-dressing for *wounds*, etc. He suggests for this compound the name ASEPTANILIDE.

ASEPSIN SOAP.—This is a pure animal-fat (tallow) soap, into which is incorporated borax and asepsin. It comes in rounded, oblong cakes of a pearly, pale, bluish-white color, approaching to olive, and has a somewhat foliaceous appearance. It is not perfumed, but possesses a clear, tallow-like odor, pleasantly modified by the presence of the asepsin it contains. It is perfectly non-irritating, and is the only medicated soap exclusively of Eclectic pharmacy. Asepsin soap is used both as a medicated soap for skin affections and as a toilet soap. Originally intended only for professional use, the laity have learned that a soap possessed of its cleansing qualities, and which leaves no odor on the skin, and is unchangeable under atmospheric influences, is the most desirable soap for toilet purposes.

Asepsin soap may be employed with safety and benefit whenever soap is desired in surgical, obstetrical, and gynecological manipulations, and is unsurpassed as a general cosmetic soap, particularly for the toilet of infants. Perfectly unirritating, it may be used on the most delicate skin, and employed where the cutaneous surface is rough and dry and the sebaceous functions imperfect. It renders the skin soft and pliable. *Acne*, *comedones*, *milium*, *seborrhœa*, *herpes*, *impetigo*, *pruritic disorders*, and *parasitic, syphilitic*, and *ulcerative affections* are benefited when a part of the treatment consists of the application of this soap. It hastens desquamation after the *exanthemata*. It removes *dandruff*, *crusts*, and *greasiness of the scalp*. In dry, scaly forms of *eczema* its application forms an important part of the treatment, and excellent results have followed its use in *acute* and *chronic rhus poisoning*. For its medicinal effects a thick lather may be applied and left to dry upon the parts, or in some instances after remaining upon the skin for from 15 to 30 minutes the latter should be removed from the surface with hot or cold water, as indicated.

ASIMINA.—PAPAW.

The seed of *Asimina triloba*, Dunal (*Anona triloba*, Linné; *Orchidocarpum arietinum*, Michaux; *Porcelia triloba*, Persoon; *Uvaria triloba*, Torrey and Gray).

Nat. Ord.—Anonaceæ.

COMMON NAMES: *Papaw*, *Pawpaw*, *Asiminer* (Louisiana), *American custard-apple*.

ILLUSTRATION: Lloyd's *Drugs and Medicines of North America*, Vol. II, plate xxxiii.

Botanical Source.—This is a small and beautiful indigenous tree, growing from 10 to 20 feet high. The young shoots and expanding leaves are clothed with

Fig. 35.

Asimina triloba.

a rusty down, soon glabrous. The leaves are thin, smooth, entire, ovate-oblong, acuminate, 8 to 12 inches long, by 3 or 4 broad, tapering to very short petioles. The flowers are dull-purple, axillary, and solitary; the petals veiny, round-ovate, the outer ones orbicular, and three or four times as large as the calyx. The flowers appear early with the leaves (which are then small), and are about $1\frac{1}{2}$ inch wide. The fruit is a yellowish, ovoid-oblong, pulpy pod, 2 or 3 inches long by about 1 inch in diameter, fragrant, sweet, edible in autumn, and contains about 8 seeds (W.—G.).

History.—The papaw (sometimes improperly called the American custard-apple tree) is an inhabitant of the Middle, Southern, and Western States, growing in rich soil, and on the banks of streams, and flowering from March to June. The fruit is large and fleshy, and has an unpleasant odor, but when ripe and after frost, the pulp is sweet, luscious, and yellow, similar to custard; it is considered a healthy fruit, and is sedative and laxative. The seeds, which are the parts used, have a fetid odor, similar to stramonium; they are covered with a tough, hard, exterior coat, of a light-brownish color and smooth externally, lighter and wrinkled internally, inclosing a kernel of a whitish-

yellow color, compressed, deeply fissured on both sides, nearly inodorous, very faintly bitter and sweetish, and dry and branny when chewed, leaving a very persistent, faint, but rather unpleasant sensation of nausea. They are of various shapes, being flat, ovoid, nearly circular, or somewhat reniform, with a longitudinal furrow or depression along the center of each of the flat surfaces, and frequently a ridge or elevation instead of the furrow. They yield their properties to alcohol. This fruit must not be confounded with the *true papaw*, from the *Carica Papaya*, an American tropical plant, whose fruit is the true *custard-apple*.

Chemical Composition.—The only chemical investigation of papaw seeds that we are aware of has been made by Prof. J. U. Lloyd, who isolated therefrom an alkaloid exhibiting anodyne properties, and to which he gave the name *asiminine*. It occurs as a white, tasteless, and colorless, amorphous alkaloid. In water it is practically insoluble, though it freely dissolves in alcohol and ether, and less readily in chloroform and benzol. Its soluble salts, and most of them are freely soluble in water, are bitter. Diluted alkalis precipitate the alkaloid from such solutions. The hydrochlorate, the salt most available for medicinal use, forms beautiful crystalline squares, or

Fig. 36.

Crystals of hydrochlorate of asiminine from alcoholic solution.

“interlocked sections of cubes,” odorless, white, “at first sweetish, then bitter, leaving a bitter after-taste.” Crystalline laminae are the forms assumed by the sulphate. Nitric acid strikes with it a *carmine* red, quickly changing to deep-black purple. The reaction is delicate, and should be differentiated from morphine, in that its color is not *blood-red*, and that it deepens to purple, and finally to dark red. It does not become lighter in color, nor does it turn yellow when treated with nitric acid. All parts of the *asimina* tree yield a fetid, volatile oil, and bitter extractive was obtained from the bark (see Lloyd's *Drugs and Medicines of North America*, Vol. II, pp. 54, 55).

Action, Uses, and Dosage.—Emetic, for which purpose a saturated tincture of the bruised seeds is employed, in doses of from 10 to 60 drops. The bark is said to be a bitter tonic, and has been used as such in domestic practice. The medical properties of this agent have not been fully investigated.

ASPARAGUS.—ASPARAGUS.

The young shoots and roots of the *Asparagus officinalis*, Linné.

Nat. Ord.—Liliaceæ.

Botanical Source.—The asparagus is a perennial plant, with an erect, round, unarmed, very branching, herbaceous stem, from 2 to 4 feet high. The leaves are setaceous, flexible, filiform, and fasciculate, from $\frac{1}{2}$ to $1\frac{1}{2}$ inches long, and of a pale-green color. The flowers are axillary, small, and greenish in color, either solitary or in pairs, and are succeeded by handsome red berries, which are globose and three-celled, each cell containing 2 seeds.

History and Description.—This herb is indigenous to Europe, and is extensively cultivated there, as well as in the United States, as an article of diet. The root has a faintly saccharine flavor, but no odor, and is active only when in the recent state. It is a short rhizome, from $\frac{1}{2}$ to $\frac{3}{4}$ inch thick. Stem-scars mark its upper surface, while from beneath many long white roots are given off, which become longitudinally furrowed on drying. The fresh roots were formerly much more used than at present, though they are still used by the French. The young shoots, which are employed as an article of diet by many, have a disagreeable taste, which is removed by boiling with water.

Chemical Composition.—Vauquelin and Robiquet (1805) found in the juice, *asparagin* ($C_4H_8N_2O_2 \cdot H_2O$), which crystallizes in right rhombic prisms, is odorless, and without taste, and refuses to dissolve in alcohol and ether. The same principle is found in other plants, notably althea, in which it was found by Bacon in 1826; also mannit, oleoresin, wax, albumen, salts, etc.

In 1870 Reinsch discovered glucose in the berries and an orange-red coloring principle, sublimable and crystallizing as scales from ether, to which the name *spargancin* has been given. The seeds contain sugar, fixed oil, a fragrant resin, and a bitter body, *spargin*, capable of crystallization.

Action, Medical Uses, and Dosage.—Both the fresh roots and shoots act as diuretics, communicating an unpleasant odor to the urine. A syrup is prepared by adding sugar to the expressed juice, deprived of its albumen by heating and straining, or an extract may be prepared from them by evaporation of the juice to a semi-solid condition. The dose of the former is from 2 to 3 fluid ounces; of the latter, from 30 to 60 grains. They are said to cause copious diuresis, and are reputed very beneficial in repressing undue excitement of the circulatory system, and have been used with advantage in *enlargement of the heart, dropsy*, etc. It is said that asparagus shoots may produce irritation of the urinary mucous surfaces, attended with a morbid mucorrhœa.

ASPIDIUM (U. S. P.)—ASPIDIUM.

“The rhizome of *Dryopteris Filix-mas*, Schott, and of *Dryopteris marginalis*, Asa Gray”—(U. S. P.). The first is the *Aspidium Filix-mas* of Swartz and others, and the *Polypodium Filix-mas* of Linné. It has many other synonyms. The second is the *Aspidium marginale* of Willdenow.

Nat. Ord.—Filices.

COMMON NAMES: (1) *Male-fern*, (2) *Marginal shield-fern*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 300; Woodville's *Med. Bot.*, Pl. 271; Johnson's *Med. Bot. of N. A.*, Fig. 160 and Pl. ix.

Botanical Source.—Male-fern (*Dryopteris Filix-mas*) has a large, perennial, tufted, scaly rhizome, sending forth yearly several leaves, 3 or 4 feet high, erect, disposed in a circle, oval, lanceolate, acute, pinnate, bright-green, and leafy nearly to the bottom; their stalks and midribs having tough, brown, transparent scales throughout; divisions alternate, taper-pointed, and pinnate; the pinnæ or leaflets numerous, crowded, sessile, for the most part distinct, occasionally somewhat combined at the base, oblong, obtuse, crenate throughout, the lateral notches broadest and most shallow, the terminal ones more crowded and acute, without any terminal bristles; both sides smooth, destitute of glandular globules, but having a depression on the upper one over the insertion of each sorus. The sori are circular, tawny, arranged in simple, close, short rows, near the partial midrib,

scarcely occupying more than the lower half of each leaflet. The indusium is circular, durable, crenate, and tumid, with a cleft terminating in the central depression. The thecae are numerous, shining-brown, and prominent all round for a little beyond the indusium (W.—L.).

Dryopteris marginale differs from the preceding mainly in having its fruit dots or sori arranged upon the margins of the fronds, the latter being from 1 to 2 feet in length, of an ovate-oblong shape, and light-green color. The pinnæ are lance-shaped, with an almost sessile, broad base; the pinnules are crowded, and are oblong in outline, with an obtuse termination.

History and Description.—Male-fern is found growing in many parts of Europe, and likewise in various sections of the United States. It is also found in South America, Africa, Asia, from the Himalayas northward, and in the islands of Polynesia. The dried root or rhizome is the official part, which, divested of its leaf-stalks and radicles, is from 8 to 12 inches in length and 1 or 2 inches thick, compressed, tortuous, tuberculous, brown or dark-brown epidermis, yellowish, rarely reddish parenchyma, fragile, striated, almost inodorous, with a nauseous sweet taste, but at last becoming rancid, slightly astringent and bitter. The fibrous radicles are covered with brown, paleaceous scales (*Ed.*). The *U. S. P.* thus describes the official drug: "From 5 to 15 Cm. (2 to 6 inches) long, 10 to 25 Mm. ($\frac{3}{4}$ to 1 inch) in thickness, and, together with the closely imbricated, dark-brown, roundish, and slightly curved stipe-remnants, 50 to 75 Mm. (2 to 3 inches) in diameter; densely covered with brown, glossy, transparent, and soft, chaffy scales; internally pale green, rather spongy; vascular bundles about 10 (*Dryopteris Filix-mas*) or 6 (*Dryopteris marginalis*) in number, arranged in an interrupted circle; odor slight, but disagreeable; taste sweetish, acrid, somewhat bitter, astringent, and nauseous. The chaff, together with the dead portions of the rhizome and stipes, should be removed, and only such portions as have retained their green color should be used"—(*U. S. P.*). The fresh root is colored bluish-black by iodine, which is indicative of the presence of starch. From the first of June to the latter part of September is the proper time for collecting it—when it should be cleansed without being washed, then dried quickly in the shade and open air without heat. Select those parts which are greenish internally, immediately pulverize them, and keep in well-closed bottles. The powder is pale greenish-yellow, and has a peculiar earthy, disagreeable odor, and the same taste as the crude root (C.). In two years the best article becomes useless.

Chemical Composition.—According to Geiger male-fern contains green fat oil (composed, according to Luck, of glycerides of *filosmylic* and *filizotic acids*), green resin, uncrystallizable sugar, easily oxidizable tannic acid, gum, salts, starch, and lignin. In addition to these Bock found fixed and volatile oil, pectin, albumen, etc. According to Peschier, the fern-buds contain a volatile oil, brown resin, fat oil, solid fatty matter, green coloring principle, a reddish-brown principle, and extractive. Three acids have been found by Dr. C. Luck in the root; two from the root itself, named "*tannaspidic*" and "*pteritannic acids*" (soluble in ether), and one from its oil, termed "*filicic acid*." The latter has the formula, $C_{14}H_{10}O_6$ —according to Grabowski (1867) or $C_{13}H_{10}O_6$ (Luck) or $C_{14}H_{10}O_6$ (Daccommo, 1889). The first-named regards it as *dibutyl-phenylphloroglucin*, for at near the fusing point of potassium hydroxide the latter decomposes it into butyric acid and phloroglucin. An impure filicic acid constituted Pavesi's (1861) *aspidin*. Malin (1867) isolated but one tannin, and to it he gave the name *filitannic acid*. Protocatechuic acid and phloroglucin result when this acid is fused with caustic potash; and when boiled with diluted mineral acids it yields glucose and *filix-red* (impure tannaspidic acid of Luck). Daccommo (*Amer. Jour. Pharm.*, 1889) found a white wax-like body, having the composition $(C_{13}H_{12}O)_n$, filicic acid, tannin, glucose, filix-red, a green oil, a brick-red, and a black, plastic resin.

Marginal shield fern yields filicic acid and a tannin probably identical with that of male-fern (Patterson, 1875).

The oil may be obtained by digesting the powdered root in pure ether, filtering, and then distilling or evaporating the ether from the ethereal tincture. It is a thick black oil, having the taste and odor of the root, reddening vegetable blues, depositing stearin when left at rest, and yielding a little volatile oil when distilled from water. Alcohol partially dissolves it; it burns with a thick smoke, and is

composed, according to Peschier, of fat, resin, volatile oil, coloring matter, extractive, chloride of potassium and acetic acid.

Action, Medical Uses, and Dosage.—*Aspidium* was the secret tænicide of Madame Nouffer, and was purchased of her by the French King in 1775. The oleoresin has been shown to be poisonous, five fatal cases out of twenty being recorded (Katayama and Okamoto, 1892). Vomiting, purging, headache, dizziness, dyspnea, cold perspiration, cyanosis, disordered intellect, profound stupor, and convulsions are among its effects. In some cases amblyopia and permanent amaurosis have occurred, though the vision is generally restored.

Male-fern is used for the expulsion of the tapeworm. Bremser says it is an excellent remedy against the *Bothriocephalus latus*, but it is not so efficient against the *Tænia solium*, and Merat entertained a similar opinion. According to Peschier the best mode of administration is the ethereal oil or extract, of which 18 grains, or from 10 to 25 drops, may be given in the form of pill or emulsion at night and again in the morning; 2 hours after the administration of the last dose a purgative dose of castor oil is to be taken, and the worm is discharged dead, without any severe or unpleasant symptoms. Dose of the powder, 1 to 4 drachms; of the ethereal tincture of the buds, which is made by digesting 1 part of the buds in 8 parts of ether, 8 to 30 drops (see also *Oleoresina Aspidii*).

Related Species.—*Polypodium incanum*, Pursh. Said to be employed by Alabama negroes to prevent conception. It is a popular Southern remedy for *dysmenorrhæa*. Emmenagogue.

Aspidium rigidum, Swartz. Europe and Pacific coast range. Contains same constituents as *Filix-mas*, and in California is used like it as a popular tænicide.

Asplenium Filix-femina, Bernhardt. Reputed tænicide. The rhizome of *Asplenium thelypteroides*, Michaux. North America. Resembles the preceding.

Aspidium Athamanicum, Kunze. South Africa. The *inkomankomo* (*uncomocomo*) of the Kaffirs and *pannum* (*Rhizoma Pannæ*) of commerce. Tæniifuge. Contains *pannic acid*, a principle closely related to *filicic acid* (see Kürsten in *A. P. A. Proceedings*, 1892, p. 606).

Scolopendrium officinarum, Smith (*Asplenium Scolopendrium*, Linné). *Hart's-tongue*. A fern indigenous to Europe and America, whose leaves have a sweetish, mucilaginous, subastringent taste. An unpleasant oleaginous odor is emitted if the leaves be rubbed. They have been variously employed as a demulcent in disorders of the respiratory tract, as a deobstruent in affections of the abdominal contents, and as an astringent in excessive discharges and hemorrhages.

ASPIDOSPERMA (U. S. P.)—ASPIDOSPERMA.

"The bark of *Aspidosperma Quebracho-blanco*. Schlechtendal"—(U. S. P.).

Nat. Ord.—Apocynaceæ.

COMMON NAME: *Quebracho*.

Botanical Source.—This tree is a large evergreen, having pendant branchlets, bearing small elliptic-lanceolate, acutely-pointed leaves, which are opposite, or tri-verticillate, and subsessile. They have entire, stiff margins. The flowers are axillary, cymose, small, and yellow. The fruit is a ligneous capsule, containing seeds having broad wings.

History.—This tree is a native of Chili and the Argentine Republic. The variety furnishing the official drug has the lighter-colored wood, another variety having a dark wood. The former comes chiefly from the province of Salta, the latter from the province of Cordoba. The wood of this tree is exceedingly hard, and the name "*quebracho*" (from *quebrar hacho*, signifying "*breaking the axe*") is given it in its native habitat, and is equally applied to all trees having wood that is very hard. The drug was introduced into Europe, in 1878, by Schickedanz. The bark is used for tanning in some parts of South America. The bark having a thick, corky layer is preferred, and is collected from the older trees.

Description.—"In nearly flat pieces, about 1 to 3 Cm. ($\frac{1}{2}$ to 1 $\frac{1}{2}$ inches) thick; the outer surface yellowish-gray or brownish, deeply fissured; inner surface yellowish-brown or reddish-brown, distinctly striate; fracture displaying two sharply-defined strata, of about equal thickness, and both marked with numerous whitish dots and striæ arranged in tangential lines; the fracture of the outer, lighter-colored layer rather coarsely granular, and that of the darker-colored, inner layer short-splintery; inodorous; taste very bitter and slightly aromatic"—(U. S. P.).

Chemical Composition.—The wood of this tree yields no alkaloids. The barks, besides containing a small amount of tannin, lævogyre inosite, and another form of sugar, denominated *quebrachit*, yields at least six alkaloids, as follows:

ALKALOID.	Discovered and named by—	Form.	Melting point.	Solubility.	Reactions.	Other properties, etc.
ASPIDOSPERMINE, $C_{27}H_{35}N_3O_3$	Schickedanz; named by Fraude (1878).	Colorless, prismatic crystals.	205° C. (401° F.).	Readily in fixed oils and fats; partially in alcohol and ether; very sparingly in water (1 in about 6000); insoluble in glycerin.	Red with warm perchloric acid, blue with platinum chloride, brown changing to bright reddish purple with sulphuric acid and bichromate of potassium.	Aqueous solution bitter. It has weak basic properties; is less poisonous than the other alkaloids. Salts principally amorphous.
ASPIDOSPERMATINE, $C_{27}H_{35}N_3O_3$	O. Hesse.....	Crystalline.....	162° C. (324° F.).		Red with warm perchloric acid.	Has strong basic properties. Salts amorphous.
ASPIDOSAMINE, $C_{27}H_{35}N_3O_3$	O. Hesse.....	Amorphous.....	About 100° C. (212° F.).		Blue with sulphuric acid and potassium bichromate.	Strong basic properties; isomeric with <i>aspidospermatine</i> .
QUEBRACHINE, $C_{31}H_{39}N_3O_3$	O. Hesse.....	Colorless crystals, changing to yellow in the sunlight.	215° C. (419° F.).	Soluble in varying degrees in alcohol, chloroform, and ether.	Yellow with warm perchloric acid; colorless with H_2SO_4 , becoming blue at rest.	Salts crystalline.
HYPOQUEBRACHINE, $C_{31}H_{39}N_3O_3$	O. Hesse.....	Yellow, amorphous mass.	About 80° C. (176° F.).	Nearly insoluble in hot benzoin.	Cherry-red with iron perchloride.	Isomeric with <i>quebrachine</i> .
QUEBRACHAMINE.....	O. Hesse.....	Colorless, silky, acicular crystals.	142° C. (288° F.).	Freely in cold alcohol and ether; sparingly in chloroform and benzoin.	Not always present in the bark.

Action, Medical Uses, and Dosage.—Quebracho is said to be valued as an antiperiodic by the Chilians. Wounds are sometimes dressed with the fluid extract. But its chief value rests upon its property of controlling *dyspnœa*, when not due to organic changes. Some, however, contend that it is equally valuable when structural changes are present. It is valuable in both *cardiac* and *asthmatic dyspnœa*, as well as in *emphysematous states*. Being a stimulant to the pneumogastric it affects chiefly the cardiac and pulmonary plexuses, and is a remedy of marked value where there is evidence of imperfect oxygenation. The cases show a disturbed relation between the pulmonic circulation and the action of the heart. In *cardiac asthma* it is reputed one of the best remedies, and to relieve the distressing dyspnœa of *capillary bronchitis*, the latter stages of *phthisis*, advanced *bronchitis*, *asthmatic bronchitis*, and simple *asthma*, with insufficient cardiac power, it has been highly praised. Pure, uncomplicated asthma is not much benefited by it, but asthma associated with emphysema is very promptly met by it. The cough of *la grippe*, with marked dyspnœa, yields to it. Dose of the fluid extract, from 5 to 60 minims, in water, syrup, or syrup of tolu, every 2 or 3 hours; for specific uses, doses of 5 to 15 minims are preferred; of the tincture, 10 to 20 minims; of commercial aspidospermine, which is a mixture of the associated alkaloids, the dose varies from $\frac{1}{4}$ to $\frac{1}{2}$ grain.

Specific Indications and Uses.—Dyspnœa of functional origin; dyspnœa with emphysema, face pale, anxious, and livid, lips cyanotic; pulse small, soft, compressible, irregular, or intermittent; orthopnœa; cardiac palpitation with cough.

Related Drugs.—*Loxopterygium Lorentzii*, Grisebach. *Nat. Ord.*: Terebinthaceæ. The *quebracho colorado* of the Argentine Republic. The wood contains a large amount of tannin and a yellow coloring matter. Hesse obtained two alkaloids, both bitter in taste, one being unnamed and the other known as *loxopterygine*. The juice of the bark forms a resinous exudation not unlike kino, and is soluble in alcohol, wood alcohol, acetic acid, acetic ether, acetone, and boiling water (Arate). Has been used as a substitute for aspidosperma, but is weaker in action.

Iodina rhombifolia, Hooker and Arnott. *Nat. Ord.*: Aquifoliaceæ. *Quebracho flojo*. Used as above and often gathered with it.

Machserium fertile, Grisebach. *Nat. Ord.*: Leguminosæ. *Tipu tree*. Uses same as preceding species.

Croton pseudochina, Schlechtendal, Mexico. Source of *Copalchi-bark*, which is occasionally sold as quebracho bark.

ASTER PUNICEUS.—RED-STALKED ASTER.

The root of the *Aster puniceus*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Red-stalked aster*, *Cocash*, *Meadow scabish*, *Squaw-weed*.

Botanical Source.—The root of this plant is perennial and fibrous. It has a hispid stem, paniculate above, furrowed, generally red, or at least on the south side, stout and tall, growing from 3 to 6 feet in height. The leaves are oblong-lanceolate, amplexicaul, more or less auriculate at the base, sparingly serrate in the middle with appressed teeth, rough above, nearly smooth underneath and pointed; the lower leaves have remote serratures, are rough-edged, rough on the upper surface, and all acuminate and narrowed at the base. The involucre is loose and longer than the disk; the scales linear-lanceolate, long, revolute, nearly equal, in two rows. The flowers are large, showy, of a pale-purple or lilac-blue color, having from 30 to 60 long, narrow rays.

History and Description.—This plant is found growing in various parts of the United States, in swamps, ditches, along the borders of small streams, and sometimes in dry soils. It flowers from July to October. The radicles or fibers of the root are the parts used; they are about the size of a pipe-stem, having a pungent, aromatic odor and taste, with some bitterness and astringency. Water or alcohol extracts their active properties. This species has several varieties—*vimineus*, *glaber*, *firmus*, and *candidus*. The second variety and the *candidus* have white flowers.

Action, Medical Uses, and Dosage.—Stimulant and diaphoretic. The warm infusion may be used freely in *colds*, *rheumatism*, *nervous debility*, *headache*,

pains in the stomach, dizziness, and menstrual irregularities. This, together with *A. cordifolius*, has been compared in value with valerian. Infusion (3ss to aqua Oj) freely.

Related Species.—*Aster sativus*, Aiton; *Rheumatic-weed*, *Sampson snake-root*, *Star flower*, etc., resembles the above plant, having lanceolate, subclasping leaves, tapering to the apex; margin rough; stem branching from its base, erect, hispid; branchlets pilose; involucre scaly; scales lax, linear, acute, equal. Flowers middle-sized, blue. It is found more abundantly west of the Alleghany Mountains, and is recommended as an antispasmodic and alterative. Principally used in the cure of rheumatism in the form of infusion or tincture; recommended, however, in hysteria, chorea, epilepsy, spasms, irregular menstruation, etc., internally; and used both externally and internally in many cutaneous diseases, the eruption occasioned by the poison rhua, and in the bites of venomous snakes. Dose of the infusion, 1 to 4 fluid ounces; of a saturated tincture, ½ drachm to 2 drachms. This plant deserves further investigation.

Aster cordifolius, Linné. *Heart-leaved aster*. United States. According to Rafinesque (*Med. Flora*, II, 198), "an excellent aromatic nervine, in many cases preferable to valerian." It is also reputed antispasmodic. The root is the part used. A decoction has been used in rheumatism.

Aster Novæ-Angliæ, Linné. *New England aster*. United States. A beautiful plant, especially when cultivated. It has rose-purple, occasionally white flowers. Used in skin eruptions and valuable for poisoning by poison sumach (Rafinesque, on authority of Dr. Lawrence).

Sericarpus tortifolius, Nees (*Aster tortifolius*, Michaux). *White-tipped aster*, *Mouse ear*. Fine barrens of the United States. Summit usually covered with insects (Forcher). Diuretic.

ATROPINA (U. S. P.)—ATROPINE.

FORMULA: $C_{17}H_{23}NO_3$. MOLECULAR WEIGHT: 288.38.

SYNONYM: *Atropia*.

"An alkaloid obtained from belladonna. As it occurs in commerce it is always accompanied by a small proportion of hyoscyamine extracted along with it, from which it can not be readily separated"—(U. S. P.).

Preparation.—An easy process for the preparation of atropine is as follows: One pound of the dry leaves of belladonna are to be boiled in distilled water sufficient to cover them for 2 hours, and the decoction strained off through a coarse cloth into a large precipitating jar. The leaves are again boiled in a second water and the decoctions mixed, to which 2 drachms of strong sulphuric acid are now added; the vegetable albumen is precipitated, and the clear liquor is drawn off with a siphon to a filter. A clear, sherry-colored solution comes through, which is either decomposed by passing gaseous ammonia through it, or by adding commercial carbonate of ammonium. In either case the color becomes changed to black, and crystals of atropine are slowly formed. At the expiration of a day or so the supernatant liquor may be drawn off with a siphon, and the crystals thrown on a filter to dry. To decolorize them, about 1 ounce of spirit of ammonia may be poured on the filter, which washes away most of the coloring matter, leaving the crystals moderately white. Purify by dissolving in boiling alcohol and recrystallizing.

Bouchardat states that by dissolving crude atropine in acidulated water, and then adding an alkaline carbonate to neutralize the acid, a deposit of resinous matter occurs at first, succeeded by a pulverulent precipitate, which is alkaline; this is atropine (though by some has been considered as a distinct substance), and has sometimes received the name of *belladonnine*.

Description and Tests.—The Pharmacopœia thus describes atropine: "White, acicular crystals, or a more or less amorphous, white powder, without odor, having a bitter, acrid taste, and gradually assuming a yellowish tint on exposure to air. Soluble at 15° C. (59° F.) in 130 parts of water, 8 parts of alcohol, 16 parts of ether, 4 parts of chloroform, and about 50 parts of glycerin. At about 108° C. (226.4° F.) it melts, forming a colorless liquid; at about 140° C. (284° F.) it begins to give off white, acrid fumes, and, when ignited, it is consumed without leaving a residue. It has a markedly alkaline reaction; its saturated aqueous solution acquires a pink color upon the addition of a drop of phenolphthalein T.S. If a small quantity of atropine, or of one of its salts, be heated with a few cubic centimeters of concentrated sulphuric acid, a peculiar odor recalling that of a mixture of rose, orange-flower, and melilot will become noticeable. On now gradually adding minute fragments of potassium dichromate the odor will change to that of oil of bitter almond, the rose odor disappearing as more dichromate is added. Atropine and its salts are decomposed by prolonged contact with sodium or potas-

sium hydrate, and if heated with either of them evolve ammonia. On dissolving a small quantity (about 0.1 Gm.) of atropine in 2 Cc. of alcohol, and adding an equal volume of mercuric chloride T.S.; a yellow precipitate, which soon turns red, is produced. On adding concentrated sulphuric acid to atropine no color should be produced (absence of readily carbonizable, organic impurities), nor should any color be developed by the subsequent addition of nitric acid (absence of and difference from morphine). The aqueous solution of atropine, or of any of its salts, is not precipitated by platinic chloride T.S. (difference from most other alkaloids). With gold chloride T.S. it gives a precipitate which, when recrystallized from boiling water acidulated with hydrochloric acid, is deposited on cooling, in minute crystals, forming a yellow, lusterless powder on drying (difference from and absence of more than a small proportion of hyoscyamine)—(U.S.P.).

The test above referred to, regarding the variety of odors produced as directed, is, beside the physiological (mydriatic) test, probably the most striking and reliable test for this substance. Manganese binoxide and potassium bichromate do not produce, with a sulphuric acid solution of atropine, a blue or purple color, thus showing the difference between this substance and *strychnine*. Its salts dissolve in water and alcohol, but are not soluble in chloroform and ether.

Chemical Composition.—The principal alkaloids contained in *Atropa Belladonna*, as atropine, hyoscyamine, hyoscyne, and belladonnine, also atropamine, are substances which bear a close chemical relationship to one another, being partly isomeric and capable of being transformed into one another, *e. g.*, hyoscyamine into atropine (Schuette, 1891; O. Hesse, 1894).

Atropine and *hyoscyamine*, both of the formula, $C_{17}H_{21}NO_3$, are capable of being resolved into the alkaloid *tropine* ($C_8H_{13}NO$) and *tropic acid* ($C_9H_9O_3$) by treatment with baryta-water, while *hyoscyne*, under these conditions, is split into *pseudotropine* ($C_8H_{13}NO$), melting at $106^\circ C.$ ($232.2^\circ F.$), and *tropic acid*.

If in these processes concentrated hydrochloric acid is employed *atropic acid* ($C_9H_9O_3$) and its polymer, *isatropic acid* ($C_{18}H_{21}O_6$) are formed, besides *tropic acid*. These reactions were first established by Kraut, in 1863, and Lossen, in 1866, and subsequently studied in detail by Ladenburg and other investigators. *Tropine* was found to be a pyridine derivative, *viz.*: *oxy-ethyl-methyl tetra hydropyridine* ($C_8H_{13}N.[C_2H_4OH].CH_3$). It is a strong, tertiary base, forming hygroscopic crystals, which melt at $62^\circ C.$ ($143.6^\circ F.$) and boil at $229^\circ C.$ ($445^\circ F.$). They are easily soluble in alcohol and water; also soluble in ether. Heated with fuming hydrochloric acid to $180^\circ C.$ ($356^\circ F.$) or acted upon by sulphuric acid and glacial acetic acid, the base *tropidine*, containing 1 molecule less of water, is formed, having the composition $C_8H_9(C_2H_5)N.CH_3$, boiling at $162^\circ C.$ ($323.6^\circ F.$), and resembling coniine in odor. In 1880 Ladenburg recognized *tropic acid* to be A-phenyl-B-oxypropionic acid ($CH_3OH.CHC_6H_5.COOH$). It is soluble in alcohol and ether, to some extent in water, from which solvent it crystallizes in needles or plates, melting at from 117° to $118^\circ C.$ (242.6° to $246.2^\circ F.$). Ladenburg, in 1884, succeeded in obtaining atropine by synthesis from its products of decomposition by evaporating a mixture of *tropic acid* and *tropine* with hydrochloric acid. By substituting other aromatic acids for *tropic acid* Ladenburg, in 1884, made known a series of synthetical alkaloids, to which he gave the name *tropines*, of this series *tropine* being the common basic constituent. *Homatropine* ($C_{17}H_{21}NO_3$) he obtained by the action of *tropine* upon *mandelic acid* ($C_6H_5.CHOH.COOH$) in the presence of hydrochloric acid. (For the chemistry of belladonna alkaloids, also see *Belladonna*.)

Action and Uses.—(See *Atropinæ Sulphas*.)

ATROPINÆ SULPHAS (U. S. P.)—ATROPINE SULPHATE.

FORMULA: $(C_{17}H_{21}NO_3)_2H_2SO_4$. MOLECULAR WEIGHT: 674.58.

SYNONYM: *Sulphate of atropia*.

Preparation.—Sulphate of atropine may be made by dissolving 80 grains of atropine in 18 fluid drachms of pure ether, and then, adding to this, drop by drop, a mixture of 3 grains of sulphuric acid, and $\frac{1}{2}$ fluid drachm of alcohol (specific gravity, 0.817), which forms a milky fluid, continuing the addition of the

mixture to saturation of the atropine. Then set the liquid aside, and when there is no further precipitate pour off the supernatant ether, and allow the residue to evaporate spontaneously to dryness (M. Ch. Maitre). In this process all the fluids used should be free from water, and the whole manipulation should be conducted in a cool place; the ether will hold any excess of acid or alkali, which, however, may be neutralized by adding a little more atropine or acid, as required.

Description.—Atropine sulphate is in the form of “a white, indistinctly crystalline powder, without odor, having a very bitter, nauseating taste, and permanent in the air. Soluble at 15° C. (59° F.) in 0.4 part of water, 6.2 parts of alcohol, 2270 parts of ether, or 694 parts of chloroform. At 187° C. (309° F.) the salt melts, forming a brownish-yellow liquid. When ignited it chars, emits acrid vapors, and is completely consumed. The salt is neutral to litmus paper. On adding sodium carbonate T.S. to a concentrated aqueous solution of the salt a white precipitate is obtained, which should respond to the reactions and tests given under Atropine (see *Atropina*). The aqueous solution of the salt yields, with barium chloride T.S., a white precipitate, insoluble in hydrochloric acid”—(U. S. P.). Atropine sulphate or its solution should strongly dilate the pupil when applied to the eye. This salt is soluble in about 3 parts of glycerin.

Action and Toxicology.—The action of belladonna and its chief alkaloids is practically identical, except in degree and rapidity. The first effect of very small doses is to cause dryness and constriction in the throat, with possibly slightly disordered vision and unpleasant sensations in the head, with vertigo and confusion of ideas. Larger doses occasion mydriasis, with dimness of sight, quickened breathing, frontal headache, with mild delirium, and in some individuals a flushing of the surface with a rash closely resembling that of scarlatina, though lacking the punctations of that eruption, and rarely causing desquamation. If toxic doses be taken these symptoms are intensified. Dimness, or total loss of sight, and extreme pupillary dilatation, with brilliant, *staring* eyes, headache, and a peculiar delirium ensue. The latter consists of fancies and illusions, hallucinations, and other phantasmagoria, with laughter and gayety, or the cerebral disturbance may lead to violent and furious delirium, with fighting propensities. The respiration is decidedly increased, as well as the frequency of the pulse, which is now hard and small, and the body temperature rises from $\frac{1}{2}^{\circ}$ to 1° F. The latter falls, however, when vaso-motor paresis takes place. These symptoms are followed by a well-marked second, or paralytic stage, with muscular weakness, and incoordination and motor paralysis, though sensation is not lost, but is, in a measure, diminished. Stupor, collapse, with feeble pulse, cold surface, and shallow, weak respiration supervene, and death takes place by exhaustion of the powers upon which the circulation and respiration depend, asphyxia preponderating as a cause of death. Narcotism never occurs, and convulsions rarely. It will be observed that full medicinal doses cause a febrile state, while toxic doses paralyze. The rapidity of the heart's action is due first to stimulation of the sympathetic cardiac ganglia, and secondarily, to paralysis of the terminal filaments of the vagus—a state of increased motor activity with decreased inhibitory power. The capillaries are contracted, but in poisonous doses dilated, allowing a fall of blood-pressure, and being due to paralysis of muscular layers of the vascular coats. Owing to vaso-motor paresis, the temperature falls from toxic doses. Atropine causes mydriasis when taken internally by being carried in the blood-current directly to the eye and there acting, as when locally applied, by causing paralysis of the terminals of the oculo-motor nerve, and it is thought also by stimulating peripheral filaments of the sympathetic. Small doses of atropine, while probably causing primary dryness of the gastro-intestinal tract, subsequently induce secretion, as is shown by the slight laxative effects of it and belladonna. It also increases tissue waste, and is eliminated almost wholly by the kidneys; and the urine so charged is said to be capable of dilating the pupil of another subject. The voluntary muscles are but little or not at all affected by atropine. A livid or cyanotic countenance is seldom observed in poisoning by atropine. After death the heart, lungs, and brain are found to be overcharged with blood. The treatment in atropine poisoning is the same as for belladonna poisoning. One-half grain killed a middle-aged man, death singularly being delayed until the sixth day; 1 grain hypodermatically proved fatal to another (see *Belladonna*).

Medical Uses and Dosage.—As a general medicinal agent atropine may be used in cases requiring belladonna, governing the dose accordingly. Such uses will be those named under belladonna. However, it does not fully represent the parent drug. There are certain cases, however, in which atropine will be preferred; in some on account of its special adaptability; in others for its prompter action. It is a powerful stimulant to the vaso-motor centers and to the capillary circulation. It has at least four well-defined fields of action, viz.: to relieve purely nervous pain; to relieve painful spasm of the involuntary muscles; to arrest excessive secretion of saliva, perspiration, and milk; and as a mydriatic. In various forms of neuralgia, where the pain originates in some nervous disorder it acts magically. Thus it is useful, in the order named, in *intercostal, trigeminal, and sciatic neuralgia*. It often fails in the latter, and the dose must be large ($\frac{1}{16}$ to $\frac{1}{8}$ grain). In *neuralgia of the stomach, ovaries, uterus*, and in other *visceral neuroses* it is an efficient remedy. In most instances it should be subcutaneously employed. By combining it with morphine when this is subcutaneously injected (say $\frac{1}{4}$ of a grain of atropine) it prevents the faintness, nausea, and tendency to retching occasionally produced by the morphine alone.

Atropine sulphate, in from 2 to 4 per cent warm solution, has been instilled into the ear for the relief of pain in *earache, non-suppurative otitis media*, and in *diffused inflammation of the aural canal*. Atropine is specifically antagonistic to excessive secretions of saliva and sweat, hence it is of much value in *ptyalism* and in the *colliquative sweats of phthisis, hectic* and other conditions of *debility*. The dose should be about $\frac{1}{16}$ grain. The value of both belladonna and atropine is well established as remedies to check the *mammary secretions*. Hence it is used both locally and internally. Atropine sulphate gives prompt relief to *spasm of the sphincters and tubular organs of the body*.

It is chiefly in ophthalmic practice that atropine has gained laurels. It has, however, been objected to on account of the conjunctival irritation and oedema, as well as the dangerous ocular tension sometimes produced, which may imperil the safety of the eye. More recently it has been replaced, to a considerable extent, by homatropine, which is said to be free from some of the disadvantages attending the use of the former.

Sulphate of atropine in solution is preferred to any other salt of this alkaloid for *paralyzing the power of accommodation*, and for *dilating the pupil of the eye*, whenever such dilatation is required; but for this purpose the salt must be pure and perfectly free from acid or alcohol, else it is apt to occasion more or less irritation. That made according to the preceding formula with ether will be found advisable. The habit of ordering a solution of atropine, to which a few drops of sulphuric acid are to be added, is objectionable on the above account, when it is designed for application to the eye. An atropine gelatin has been made for the purpose of dilating the pupil, and which is preferred by some oculists to the solution. It consists of a thin layer of gelatin, with which has been mixed some sulphate of atropine. This layer is marked out into discs or squares, each one of which contains about $\frac{1}{16}$ of a grain of sulphate of atropine. One of these discs placed upon the eye, between the ball and the lid, dissolves rapidly and causes dilatation. When it is desired to paralyze the power of accommodation it is prepared of greater strength (see also *Lamellæ Atropinæ—Br.*). It is largely used where inspection of the interior of the globe is sought, and in such operations as *cataract*, etc. It is a very valuable agent, but may do irreparable injury if inappropriately used. *Glaucoma* always contraindicates it, and in old people more or less danger attends its use, and even glaucoma may result from it. It is also contraindicated in *phlyctenular keratitis* after subsidence of the acute phases; in *marginal corneal ulcers*; in *keratitis* with superficial vascularity, and in all cases of *over-tension of the ocular globe*. On the other hand, it is the remedy in *iritis*, from start to finish, and in *central perforating corneal ulcers* it should be used sufficiently strong and often to insure continuous ciliary paralysis, thereby insuring full dilatation of the pupil, and in the latter instance preventing the iris from adhering to the ulcerated cornea. After operations for *cataract, iritis*, as a complication, is averted by the use of atropine, and it should be employed also in *deep, interstitial keratitis*. *Intermittent strabismus* and consequent *eye-strain*, as well as *chorea* from eye-strain, have been corrected by this drug, followed by the selection of the proper lenses.

In the *acute stage of phlyctenular keratitis* it may be employed to check the flow of tears and sensitiveness to light, discontinuing the drug as soon as the active inflammation has been subdued. Haziness of the cornea in *ophthalmia neonatorum* is the danger signal in this trouble, and the prompt use of atropine sulphate will prevent involvement of the corneal and deeper structures of the eye. As an eye remedy it may be used as the exigencies of the case demand. Foltz uses, R Atropine sulphate, grs. ss to grs. xvi; water, add fl̄i, the stronger solutions to be used by the physician himself. A solution not stronger than 4 grains to the ounce is dispensed, to be used by the patient 3 times a day. Dilatation is produced in 10 or 15 minutes, and usually persists for 3 or 4 days.

Both atropine and belladonna are antagonistic to *opium poisoning*, and have been used as strong as $\frac{1}{2}$ grain every hour for 5 hours. It is also antagonistic to *eserine* and *pilocarpine*, and has been successfully used in *strychnine poisoning* and *chloroform* and *ether narcosis*. Frazer used it ($\frac{1}{16}$ to $\frac{1}{8}$ grain) with morphine sulphate ($\frac{1}{8}$ to $\frac{1}{2}$ grain) hypodermatically before anæsthetizing with chloroform, claiming that it lessens the excitement, takes less chloroform, and longer sustains the action of the latter. Sulphate of atropine ($\frac{1}{16}$ grain) placed directly upon the sensitive pulp of a tooth is said to promptly check the pain, and a solution has been applied to *cancerous ulcers* to allay pain. Sulphate of atropine, on account of its greater solubility, is preferred to atropine itself, and both are given in the same-sized doses, $\frac{1}{16}$ to $\frac{1}{8}$ grain, the larger doses only in extreme cases, as in narcotic poisoning. The solutions should be fresh, as they are apt to develop fungoid growths, with decomposition of the alkaloid. An ointment containing 3 grains of atropine sulphate rubbed upon an ulcer of the neck is said to have produced death in 2 hours.

Sulphate of atropine is generally used in solution in hypodermatic injection, the quantity injected at a time varying from $\frac{1}{8}$ to $\frac{1}{16}$ of a grain of the salt. The solution may be made by dissolving 1 grain of the sulphate in 4 fluid drachms of distilled water; 4 minims of this contain $\frac{1}{8}$ of a grain of the salt; the amount to commence with is 2 minims, which may be cautiously increased to 3 or 4 minims.

Dr. A. Fleming preferred the following solution of atropine for internal use: Take of atropine, 1 grain; distilled water, 5 drachms. Dissolve thoroughly with the aid of a few drops of diluted hydrochloric acid, and add of rectified spirit sufficient to make 10 drachms. This solution keeps well, is of uniform strength, and is much safer and more efficient than some other preparations of belladonna. Ten minims contain $\frac{1}{8}$ of a grain of atropine, which is the commencing dose for an adult; it should be given in a little water, once daily, at bed-time, and on an empty stomach. The dose may be increased daily by 2 or 4 minims until some of the physiological effects are slightly produced, as dry throat, dilated pupil, and dim sight. For children under 1 year the dose is 1 minim; of 2 years, 2 minims; of three years, 3 minims, and so on up to ten years, when 10 minims may be given. It is, however, too dangerous, as an internal medicine, for children, minute doses of belladonna being preferable. Atropine should never be given in pill form, lest from slow or deficient solution it may accumulate in the stomach or bowels, giving rise to severe atropism.

Related Salts of Atropine. — **ATROPINÆ VALERIANAS.** *Valerianate of atropine* may be made by dissolving a sufficient quantity of monohydrated valerianic acid in a sufficient quantity of pure ether, saturating this solution with atropine, and allowing the liquid to spontaneously evaporate. The salt is deposited in the form of light, white scales, consisting of a mass of small crystals, which is very soluble in water, less so in alcohol or ether, which fuses at 32.2° C. (90° F.) and becomes yellow by exposure to light and air.

M. Michea recommended the valerianate of atropine in *spasmodic or convulsive diseases*, in doses of a milligramme per day for an adult, on commencing its use; he considered it superior to either valerian or belladonna, on account of its small dose and its certainty of action. It is also recommended in various *chronic nervous complaints*. The dose is $\frac{1}{16}$ to $\frac{1}{8}$ of a grain, repeated 2 or 3 times a day.

ATROPINÆ SALICYLAS. — *Salicylate of atropine* forms in deliquescent, non-crystalline, colloidal masses, soluble in water and alcohol, and must be kept in securely-stoppered bottles. It may be prepared by taking a little more than 2 parts (288 grains) of atropine and 1 part of salicylic acid (137 grains) and dissolving them in water (20 ounces), and gently evaporating the solution. When pure it is reputed to act more efficiently and with greater rapidity than sulphate of atropine. The dose is the same as for the latter salt.

ATROPINÆ SANTONICUM. — *Atropine santonate* is formed by the union of atropine and santonitic acid. It forms an amorphous powder unaffected by atmospheric moisture, but dissolves

with facility in water, forming a solution which, if kept in amber-colored vials (prevents formation of photo-santonin acid), undergoes no change, hence its advantage over the other salts of atropine. Another advantage is that it is said to be perfectly unirritating.

For *Scopoline* see *Related Products*, under *Belladonna*; see also *Homatropine hydrobromate*.

Related Species and Principles.—*Ephedra vulgaris*. Japan. A plant of the order *Gentianeae*, from which Nagai of Tokio isolated the alkaloid *ephedrine* ($C_{10}H_{15}NO$). The latter body produces death in the lower animals by both cardiac and respiratory paralysis. It is a local mydriatic, producing, in 10 per cent solution, an incomplete dilatation of the pupil in from $\frac{1}{2}$ to 1 hour, the normal condition being regained in from 8 to 20 hours. The accommodation is scarcely affected. It is not likely to come into general use.

Ephedra monotachya, Linné.—Root and branches used in Siberia in *syphilis* and *gout*. The alkaloid, according to Kobert, is non-toxic and non-mydriatic, and therefore unlike *ephedrine*. This view is supported by P. Spehr (*Amer. Jour. Pharm.*, 1892), who finds the alkaloid to be distinct with the composition $C_{12}H_{19}NO$, while that of *ephedrine* is $C_{10}H_{15}NO$.

Ephedra antisiphilitica, C. A. Meyer.—*Mormon tea*, *Mountain rush*, *Whore-house tea*, *Brigham weed*. Nevada. Used in *gonorrhoea* in doses of 1 to 2 fluid drachms of the fluid extract. The medicinal activity depends, in the opinion of Loew, upon a tannin.

GLDITCHINE.—Dr. Lautenbach (1878) found this alkaloid in the *Gleditschia triacanthos* and *Gleditschia ferox*. The same alkaloid was afterward introduced under the name *stenocarpine* before it was known to be the product of *G. triacanthos*. The former name was then restored. The alkaloid was introduced as a local anæsthetic and mydriatic. A solution at one time upon the market was shown to contain cocaine in considerable amounts, besides some atropine or a similar mydriatic, since which *gleditchine* has fallen into disrepute.

TETRAHYDRO-B-NAPHTHYLAMINE ($C_{10}H_9H_4.NH_2$).—An extraordinarily powerful local mydriatic, said to be even more powerful than atropine. A 1 to 5 per cent solution is used (Filehne).

AURANTII AMARI CORTEX (U. S. P.)—BITTER ORANGE PEEL.

"The rind of the fruit of *Citrus vulgaris*, Risso"—(U. S. P.) (*Citrus Aurantium*, var. *amara*, Linné; *Citrus Bigaradia*, Duhamel).

Nat. Ord.—Rutaceæ.

COMMON NAMES: Bitter orange, Bigarade orange, Seville orange.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 50.

Botanical Source.—The bitter orange tree is scarcely distinguishable botanically from the sweet orange tree (see *Aurantii Dulcis Cortex*), except in its leaves, fruit, and flowers. The leaf stalk of the bitter orange is more broadly winged, and the fruit itself of deeper hue of red, having a rougher rind, and a bitter, sour juice. Added to these characteristics all portions of the bitter orange emit a greater fragrance than the same parts of the sweet variety. By some botanists this tree is regarded merely as a variety of the *Citrus Aurantium* of Linné (see *Aurantii Dulcis Cortex*).

Description.—I. THE RIND (*Aurantii amari cortex*). The U. S. P. describes bitter orange peel as consisting of "narrow, thin bands, or in quarters; epidermis of a dark, brownish-green color, glandular, and with very little of the spongy, white, inner layer adhering to it; it has a fragrant odor, and an aromatic, bitter taste"—(U. S. P.). (For further information regarding bitter orange, see *Aurantii Dulcis Cortex*.) It is official in *Extractum Aurantii Amari Fluidum* and in *Tinctura Aurantii Amari* of the U. S. P.

II. THE FRUIT (*Fructus aurantii*), when ripe, is about the shape and size of the common sweet orange, is darker in color, rougher, and has a white parenchyma beneath the rind, and the juice of the pulp is bitter and sour. Orangettes (*petit grains*) are the unripe fruits which drop from the trees, and are considerably used on the continent under the name of *orange berries*. They vary from $\frac{1}{2}$ to $\frac{3}{4}$ inch in diameter, are of a greenish or brown-black color, closely wrinkled, and pleasantly aromatic both in taste and odor.

III. THE LEAVES (*Folia aurantii*).—These are borne on a jointed, broadly-winged petiole, and are smooth, oblong-ovate or ovate, nearly entire, or having a slightly crenated margin. They are aromatic and have pellucid oil-glands scattered throughout the blade.

Chemical Composition.—A bitter crystalline body was isolated in 1828 by Lebreton and named *hesperidin*. It exists in the white parenchymatous tissues of both the orange and lemon rind, but is found in greatest abundance in the unripe Seville orange. It occurs, when purified, in white, acicular crystals, practically insoluble in water, even when hot. (1 in 5000 of boiling water). It

dissolves in boiling acetic acid and in alcohol, but refuses to dissolve in ether, fats, essential oils, and benzol. Treated with diluted acids it is split into grape-sugar and *hesperetin*, insoluble in alcohol. *Hesperidin* fuses at 245°C . (473°F .); *hesperetin* at 223°C . (433.4°F .). A substance analogous to tannin, gum, resin, albumen, fixed oil, and an essential oil (see *Oleum Aurantii Corticis*) have also been found in the rind.

The juice of the orange consists chiefly of sugar, mucilage, and citric acid. Tanret (1886) found in bitter orange peel a bitter, acrid resin, a crystallizable, tasteless acid having the formula $\text{C}_{44}\text{H}_{20}\text{O}_{16}$, *hesperidin*, an isomeric glucoside (*isohesperidin*, $\text{C}_{44}\text{H}_{20}\text{O}_{16} \cdot 5\text{H}_2\text{O}$) and another glucoside (*aurantiamarin*), to which he attributes the bitterness of the rind on account of its solubility in water.

Action and Medical Uses.—(See *Aurantii Dulcis Cortex*.)

AURANTII DULCIS CORTEX (U. S. P.)—SWEET ORANGE PEEL.

"The rind of the fresh fruit of *Citrus Aurantium*, Linné"—(U. S. P.) (*Citrus dulcis*, Link).

Nat. Ord.—Rutaceæ.

COMMON NAMES: *Sweet orange*, *Portugal orange*, *China orange*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 51.

Botanical Source.—*Citrus Aurantium* is a middle-sized evergreen tree, with an arborescent stem, covered with bark of a greenish-brown color, having axillary

Fig. 37.

Citrus Aurantium.

spines on the branches. The leaves are alternate, ovate-oblong, acute, slightly serrulated or entire, shining green, the stalk more or less winged. The flowers are large, white, rendering the atmosphere around very fragrant; the calyx urceolate and 5-cleft: the petals 5, oblong; the stamens 20 or even more; the filaments compressed at the base, more or less united there, and polyadelphous; the anthers oblong and yellow. The ovary is many-celled. The fruit is roundish, golden-yellow or tawny, and several-celled, with a fleshy, juicy pulp; the seeds white and several. The cysts in the rind are convex (L.).

Description, History, and Chemical Composition.—The orange is a native of Asia, and is cultivated in the southern parts of Europe and America and in the West Indies. Its varieties are numerous. The fruit likewise varies in its character, that of the *C.*

Aurantium, the China orange, being sweet, while that of the *C. vulgaris*, the Seville orange, is acid and slightly bitter. The ordinary commercial oranges are subvarieties of the sweet orange, and usually take their names from the country where grown, or the shipping ports from which they are sent out. Some varieties are seedless, as *St. Michael's orange*, and generally the *Navel orange* of Brazil; another variety having a reddish pulp is known as the *Blood orange* or *Maltese orange*. The *Mandarin orange* differs considerably from the common orange, and on account of its delightful fragrance and flavor the name *Citrus deliciosa* has been proposed for it by those who regard it as a distinct species.

The leaves of the orange are studded with vesicles containing volatile oil, and have a bitter, aromatic taste, and when rubbed between the fingers are very redolent. They, together with the young twigs, yield by distillation an oil termed *essence de petit grain*. The original oil bearing this name was distilled from orange berries. It does not differ chemically from orange-oil, though it has a different odor. An infusion of the leaves is sometimes employed as a gently-stimulant diaphoretic. The flowers have a delicious fragrance, which is imparted to the surrounding atmosphere, but which is lost by drying; those of the bitter orange are considered the most delicate. They owe their aroma to an essential oil, which may be obtained by distillation; it is termed *oil of neroli*, and is much used in perfumery. An *orange flower water* is prepared in Italy and France, which is quite pale, has a rich odor of the flowers, and a bitterish, aromatic taste; it is employed

for the purposes of perfumery, although reputed to possess antispasmodic virtues. The peculiar fragrance of the flowers may be preserved for a long time by beating them into a pulp with one-fourth their weight of common salt. The juice of the orange consists chiefly of sugar, mucilage, and citric acid. The outer rind of the mature fruit is the official part, the inner being destitute of useful properties, and the two should always be separated from each other when drying the rind for medicinal purposes, as the spongy, inner rind is apt to occasion moldiness from its absorbing moisture from the air. Orange-peel has a deep orange color, a grateful aroma, and a pleasantly bitter taste, the Seville variety being more bitter than any other. It contains a volatile oil in visible vesicles, mostly lost in drying, a saccharine principle, *hesperidin*, and a ligneous fiber, agreeing in composition with bitter orange peel, though containing a lesser amount of the bitter principle. The fresh rind, grated and expressed, will yield the volatile oil, or it may be obtained by distilling the fresh rind with water. Water or alcohol takes up the sensible properties of the rind. The finest orange oil, which must not be confounded with the oil of neroli, is obtained from Portugal, and is prepared from the rind of the sweet orange. It has a pale straw tint and a rich fragrance of the rind. It is imported in tinned copper cans, and is much used in perfumery and for other purposes. On exposure it spoils rapidly, acquiring a turpentine odor. When about the size of a pea or cherry, the bitter fruit is sold under the name of *oranges*, that variety coming from the isle of Curaçao being known as *Curaçao oranges*; and the small ones are sometimes used to maintain the discharge from issues. The U. S. P. describes the official drug as "closely resembling bitter orange peel, but having an orange-yellow color. It has a sweetish, fragrant odor, and an aromatic, slightly bitter taste." It is used in the preparation of *Syrupus Aurantii* and *Tinctura Aurantii Dulcis* of the U. S. Pharmacopæia.

Test.—A test to distinguish orange peel from lemon peel was recently proposed by E. G. Clayton. It consists in moistening the rind with strong hydrochloric acid. The orange peel is stated to acquire a rich, dark-green tint, while lemon peel assumes at most a dingy, yellowish-brown color (*Amer. Jour. Pharm.*, 1894).

Action, Medical Uses, and Dosage.—Orange peel is aromatic and slightly tonic, but is seldom used except to cover the taste of disagreeable medicines or to lessen their tendency to nausea, and for these purposes it is frequently added to bitter tinctures, infusions, etc., as quassia, Peruvian bark, etc.; though care should be taken not to subject it to long boiling on account of its oil, which will thus be dissipated. As a tonic the rind of the Seville orange is preferred; its dose in substance is from 30 to 60 grains 3 times a day. Large quantities of it have caused violent colic, convulsions, and even death. The juice of the orange is not only a light refrigerant article of diet, but has a direct beneficial medicinal influence in several diseases; as in all fevers and exanthematous diseases, where acids are craved, and the patient's tongue is coated deep-red, brown, black, or any intermediate color; in such cases its free use may be allowed with advantage; it is also useful as an antiscorbutic in *scurvy*. In administering the juice the membranous portion should always be carefully rejected (see also *Aurantii Flores*).

AURANTII FLORES.—ORANGE FLOWERS.

The fresh flowers, partially expanded, of *Citrus Aurantium*, Linné, and *Citrus vulgaris*, Risso.

Nat. Ord.—Rutaceæ.

Description.—Orange flowers are composed of a small, cotyloid, 5-parted calyx and 5 white, fleshy, oblong, obtuse petals, which are dotted here and there with glands. They are about $\frac{1}{2}$ inch in length. The filaments of the stamens, which are about 20 in number, are united below into bundles (3, sometimes more). The ovary, which is globular, rests on a disk, and is surmounted with a round style, capped with a globe-like stigma. The odor of orange flowers is exceedingly and pleasantly fragrant, the bitter variety possessing this quality more than the sweet orange. They have an aromatic, bitterish taste. When dried the petals are of a pale, brown-white color. The flowers may be preserved for some time by adding

to them half their quantity (by weight) of common salt, and pressing them into a jar, which should then be securely closed and kept in a cool, dark situation.

Chemical Composition.—Orange flowers contain an essential oil (see *Oleum Aurantii Florum*), acetic acid, gum, salts, and bitter extractive (Boullay, 1828); the bitterness of the latter is thought to be due to *hesperidin* (see *Aurantii Amari Cortex*).

Action, Medical Uses, and Dosage.—Orange flowers are used in the preparation of orange-flower water, which may be employed as a vehicle for the administration of medicines. It is slightly stimulant to the nervous apparatus, and is said to have proved beneficial, in doses of 1 or 2 fluid ounces, in *chorea*, *hysteria*, *epilepsy*, and many other *nervous disorders*.

AURI ET SODII CHLORIDUM (U. S. P.)—GOLD AND SODIUM CHLORIDE.

"A mixture of equal parts, by weight, of dry gold chloride ($\text{AuCl}_3=302.81$) and sodium chloride ($\text{NaCl}=58.37$). It should be kept in well-stoppered vials"—(U. S. P.).

SYNONYM: *Chloride of gold and sodium.*

Preparation.—1. Dissolve 4 parts of gold in nitro-hydrochloric acid, evaporate the solution to dryness, and treat the dried mass with 8 times its weight of distilled water containing in solution 1 part of well-dried, common salt. Evaporate the solution nearly to dryness, stirring all the time with a glass rod (Figuiet). 2. Dissolve 85 parts, by weight, of chloride of gold (auric trichloride) and 16 parts of chloride of sodium in a small quantity of water; evaporate the solution by a gentle heat until a pellicle forms, and then put aside to crystallize. As prepared by the French from proper proportions of solutions of auric trichloride and sodium chloride, and evaporated to crystallization, it forms in yellowish-red, permanent rhombic crystals of the composition $\text{NaCl} \cdot \text{AuCl}_3 \cdot 2\text{H}_2\text{O}$. In this country it is most generally prepared by dissolving equal weights of gold chloride and sodium chloride and evaporating to dryness.

Description and Tests.—The crystallized double salt is in the form of prismatic, quadrangular, and elongated crystals, of a very bright-yellow color, permanent in the air, unless they contain uncombined trichloride, when they are slightly deliquescent. They are soluble in water. When heated they give out water, and then melt, and at a red heat give out chlorine; but it requires a very long-continued application of heat to drive off the whole of the chlorine. The salt more generally employed is that of the U. S. *Pharmacopœia*, which should agree with the following description and tests: "An orange-yellow powder, odorless, having a saline and metallic taste, and slightly deliquescent in damp air. The compound is very soluble in water, and at least one-half of it should be soluble in cold alcohol. When exposed to a red heat it is decomposed, and metallic gold is separated. A fragment of the compound imparts a persistent, intensely-yellow color to a non-luminous flame. Its aqueous solution has a slightly acid reaction, and yields, with silver nitrate T.S., a white precipitate insoluble in nitric acid. On bringing a glass rod, dipped into ammonia water, close to a portion of the compound, no white fumes should make their appearance (absence of free acid). If 0.5 Gm. of gold and sodium chloride be dissolved in 50 Cc. of water in a porcelain capsule, the solution acidulated with 5 Cc. of diluted sulphuric acid, and, after the addition of 1 Gm. of pure oxalic acid, heated for about 2 hours on a water-bath, a precipitate of metallic gold will be obtained, which, when washed, dried, and ignited, should weigh not less than 0.15 Gm. (corresponding to at least 30 per cent of metallic gold). The filtrate from the precipitated gold should not be affected by hydrogen sulphide T.S., nor, after being supersaturated with ammonia water, by ammonium sulphide T.S. (absence of metallic impurities)"—(U. S. P.). Of all the preparations of gold, this is the most to be relied upon. When taken into the system, being a soluble salt, it is excreted and passed off by the skin and kidneys, principally the latter. It is incompatible with most vegetable and mineral acids, earths, most vegetable juices, and the oxides or salts of other metals. The simpler the form in which it is prepared for administration, the less liability will there be of its decomposition.

Action, Medical Uses, and Dosage.—The salts of gold closely resemble those of mercury in their effects upon the human system. The chloride of gold is caustic, and even more poisonous than corrosive sublimate. An erethism, not unlike the fever of mercurialism, is said to be produced by its long-continued use, and the sexual functions are said to be stimulated by gold preparations. Bromide of gold is twenty or more times as powerful as the commonly employed bromides. The chloride of gold and sodium has been found by Bartholow to have a marked action when long continued in causing a waste of connective tissue, a fact taken advantage of in certain diseases characterized by an over-abundance or over-production of that tissue.

Among the effects of auric preparations are the following: Small medicinal doses promote the appetite and digestion, but their long-continued use induces constipation. Full doses occasion gastric irritability, nausea, and anorexia. Long continued they produce a fever (auric fever) with colligative sweats, marked diuresis, and ptialism, differing, however, from mercurial ptialism in not producing tenderness or ulceration of the gums. The mind becomes active under auric medication, and may be excited, followed by cheerfulness. Among the earliest uses of gold we find it principally a remedy for mental disorders. Increased sexual desire in the male, with erections, amounting sometimes to priapism, takes place, while both sexual desire and the menstrual function are augmented in the female. The preparations are chiefly eliminated by the kidneys, though to some extent by the skin and bowels. Over-doses of the gold salts are to be treated with the same antidotes as for the mercury compounds.

Gold was formerly employed in the form of the triturated leaf in many of the conditions in which the so-called double chloride is now employed. The chloride of gold and sodium in small medicinal doses is endowed with general stimulant and diuretic properties, acting also as an energetic alterative. It has been highly recommended in primary and secondary *syphilis*, *scrofulous* and *herpetic affections*, *goitre*, *scirrhus tumors*, *ophthalmic affections*, *dropsy*, etc. It is principally used among Eclectic physicians as an antisymphilitic, and as such it is of decided efficacy. In four cases where some of the virus from chancres had accidentally lodged in the eye, producing symptoms threatening a loss of that organ, I saved the eyes by bathing them several times a day, with a wash made by dissolving 7 grains of the chloride of gold and sodium in a fluid ounce of distilled water, likewise using the salt internally (J. King). The cases in which gold and sodium chloride acts favorably are those showing a moderately red tongue and fair surface-circulation in *secondary syphilis*, *glandular affections*, and in certain *chronic skin diseases*. The tongue is contracted more than ordinarily, and the symptoms are secondary or tertiary. When *chancres* and *buboes* are present they are indolent and of the non-sensitive variety. The dose should be small— $\frac{1}{16}$ to $\frac{1}{8}$ grain in pill.

Of recent years gold and sodium chloride has been quite extensively used in certain *mental disorders* and *bone diseases*. This use has been borrowed from homœopathy, and the strength of preparations used is the 3 x to 6 x triturations. A keynote for the use of the drug in these attenuations seems to be a melancholic state of mind, with despondency and desire for death or disposition to suicide. These indications are all the more strengthened if the individual be one whose system is shattered with syphilis. Thus this salt, as well as the arsenate of gold, has been used in the *chronic headaches* dependent upon *syphilitic periostitis*, *ozena*, and *bone necrosis*, especially in *caries of the nasal bones*, for which it appears to have a selective affinity. From the earliest times gold has been known as an efficient remedy for *hypochondriasis*, and this action has been put to good use by homœopaths. The mental and nervous disorders in which it may be employed are *insanity* from sexual excesses, *melancholia*, with suicidal mania, and *hypochondriasis*, due to disorders of the testes or liver. *Chronic bone-pains*, *pericranial* and *periosteal pain*, and *neuralgia* are cases for it, particularly when a syphilitic taint is present. Where the neuralgic element is strong the arsenate is preferred. Diseased states arising from the abuse of mercury, as in *ulceration of the throat*, are to be treated with this drug.

That gold and sodium chloride would increase waste of connective tissue led Bartholow and others to employ it, where it was desired to prevent the over-

production of that tissue—*hyperplasia* in any organ. Thus it has been used in *chronic interstitial nephritis*, and other like affections, in $\frac{1}{10}$ grain doses. *Uterine* and *ovarian indurations* are reduced by it (3 x trituration). *Chronic sexual disorders*, with involvement of the structures, are thought to be benefited by its use. Among these troubles are *erotomania*, *nocturnal pollutions*, *premature emissions*, and *sexual irritability*, as well as *testicular atrophy* after *epididymitis* and *sarcocoele*.

In ophthalmic and aural practice it is said to be efficient where the iodides are not well received. *Caries of the orbit* of scrofulous nature, *deep keratitis* from hereditary syphilis, and the *iritis* and *keratitis* of acquired syphilis are disorders in which it is of service (Foltz). Dose, $\frac{1}{10}$ grain. In ear diseases Foltz finds it of value in such cases as depend upon *hereditary syphilis*, but of little value in acquired syphilis. He claims brilliant success from its use in *suppurative otitis media*, where caries is a prominent feature. Dose, $\frac{1}{10}$ to $\frac{1}{5}$ grain every 4 hours. (For the further use of this drug in minute doses, see Webster's *Dynamical Therapeutics*.)

The dose of gold and sodium chloride internally is from $\frac{1}{2}$ to $\frac{1}{10}$ of a grain, which may be given in pill form or in solution, thus: Dissolve 2 grains of chloride of gold and sodium in a fluid ounce of water, of which the dose is 10 or 15 drops every 2 or 3 hours. For pills mix 2 grains of the salt of gold with 1 drachm of powdered starch, lycopodium, or orris root, and form into a pill mass with a sufficient quantity of gum Arabic in solution; divide into 40 pills, each of which contains $\frac{1}{20}$ of a grain of the gold salt. Or it may be given in powder made by rubbing together 1 grain of the salt with 1 drachm of white sugar, or sugar of milk, and dividing into 12, 15, or 20 powders, according to the dose required. It has, however, been given in doses of from $\frac{1}{4}$ to $\frac{1}{2}$ grain, 3 times a day, and without any unpleasant consequences; but when such doses are prescribed its action should be carefully watched, and its administration be suspended for a time. Its effects upon the system in over-doses, or when the patient contracts cold while under its influence, are said to be equally as severe and dangerous as those following the use of corrosive sublimate, under the same circumstances. The 3 x and 6 x triturations are given in 2 or 3-grain doses 3 or 4 times a day. Externally it may be applied to scrofulous and syphilitic *ulcers* in solution, or made into an ointment with prepared lard, in the proportion of 7 or 9 grains to the ounce of water or lard.

Specific Indications and Uses.—Tongue contracted and redder than usual, syphilis, especially in secondary and tertiary stages, and in the hereditary form; non-sensitive and indolent buboes and chancres ($\frac{1}{10}$ to $\frac{1}{2}$ grain). Melancholia, with suicidal propensity, depressed spirits, hypochondriasis, and troubles associated with these symptoms; syphilitic caries (3 x trituration).

Gold and Its Compounds.—AURUM. Symbol, Au. Atomic weight, 196.2. Gold is the chief of the precious metals, as well as being the most ductile of metallic substances. It is the only element having a bright-yellow hue, and is named from its lustrous, shining color. It is found naturally in the earth free and combined. It exists in sea water, and is occasionally met with as an amalgam. *Moss gold* is native gold, the crystals of which are so arranged as to resemble golden threads. Gold is obtained in the mining districts by agitating the crushed earthy material with water, whereby the heavier gold falls to the bottom, and is then dissolved from the mineral admixtures by agitation with mercury. The amalgam thus obtained is then distilled, whereby the mercury passes over and the gold remains behind. Of late years advantage is taken of the solubility of gold in potassium cyanide to extract gold from poor ores. Such ores could not be worked at all by the old process. Some idea of the ductility of gold may be gathered from the following statement from Lloyd's *Chemistry*, that when hammered "280,000 thicknesses of gold-leaf will only occupy 1 inch in thickness, and 1 grain of gold will gild 2 miles of silver wire."

Gold may be so finely attenuated that the precipitate will remain suspended in water, even though its density is much greater than that of the latter. According to Matthiessen its specific gravity is 19.265. It is wholly unaffected by oxygen or water, nitric and the other concentrated mineral acids should have no action on it, nor should ammonia tarnish it. Nitro-hydrochloric acid (*aqua regia*), however, dissolves it readily and completely, nascent chlorine being the agent which accomplishes its solution. Pure gold is too soft for coin and trinkets, hence it is generally alloyed with copper or silver, the former imparting to the alloy a reddish tint, while the latter occasions a pale-yellow hue. With mercury it forms an amalgam. In making and selling jewelry the term *carat* is employed, pure gold being represented by "24 carat"—an "18 carat" gold, for example, meaning an alloy of 18 parts of gold and 6 parts of copper or silver. The chief salt of gold used in medicine is the chloride in the combination of gold and sodium chloride.

AURUM FOLIATUM.—*Gold-leaf* is a transparent, bluish or greenish film, used sometimes as a *pill-coating*.

AURI PULVIS.—*Pulverized or powdered gold*. This may be made by triturating until lustreless a quantity of gold-leaf with some gritty substance like milk-sugar, or other hard crystalline substance which is soluble. The gold is washed with water.

AURI ET AMMONII CHLORIDUM.—*Gold-ammonium chloride*. This salt resembles auric chloride, and is made by dissolving in water equal amounts of gold chloride and ammonium chloride, hydrochloric acid being added to acidulate the solution; and finally evaporating to dryness.

AURI CHLORIDUM.—*Auric trichloride, Chloride of gold* (AuCl_3). Dissolve gold coin in nitro-hydrochloric acid, evaporate to dryness, dissolve the residue in water, and pour the solution into an excess of ferrous sulphate. Metallic gold is thrown down as a black precipitate. Wash the precipitate well, dissolve in nitro-hydrochloric acid, and evaporate to dryness. Dissolve the residue in a little water, and again evaporate to dryness and place the product at once in well-stoppered bottles. This salt in mass is dark-red, but yellowish-red when powdered. It should have no greenish tinge, and should dissolve completely in water, alcohol, and ether (see Lloyd's *Chemistry*, p. 346). With solution of stannous chloride it forms "purple of Cassius," a deep, brownish-purple precipitate. Auric chloride is used in testing for alkaloids, with which it forms insoluble precipitates.

AURI OXIDUM $\text{Au}(\text{OH})_3$.—*Gold hydroxide, Auric acid* (so-called). A very dark, almost black-brown powder. This may be prepared by strongly alkalizing with caustic potash a cold solution of auric chloride, and precipitating the solution with barium chloride. Aurate of barium results, and this, when treated with diluted nitric acid, leaves its barium in solution, and pure oxide of gold remains (M. L. Figuier). It may also be obtained by precipitating a solution of chloride of gold with magnesium oxide or zinc oxide, the precipitate being washed on a filter successively with diluted nitric acid and water. This does not give so large a yield as the preceding process.

AURI CYANIDUM.—*Cyanide of gold*. A tasteless, odorless, lemon-yellow salt, prepared by adding to pure gold chloride in solution an equal quantity, by weight, of pure cyanide of potassium in aqueous solution. Should too much of the latter salt be employed a darker precipitate, which is not desirable, would be formed. This salt contains 75 per cent of metallic gold (Figuier's process). *Auro-potassium cyanide*, in colorless, plate-like crystals, may be produced by employing a strong, hot solution of cyanide of potassium in excess. It effloresces and becomes white on exposure to the air. It contains gold amounting to 55 per cent.

AURI IODIDUM.—*Iodide of gold* (AuI_3). A deep-green powder, made by precipitating gold chloride from solution with iodide of potassium, taking the precaution not to have an excess of the potassium salt. Wash well with water and carefully dry the compound. When exposed to the atmosphere it liberates iodine, being successively converted into *aurous iodide* (AuI) and metallic gold. Potassium iodide solution dissolves it.

AURUM BROMIDUM.—*Gold bromide* is recommended by Hale (*Hom. News*) as a remedy for *somnambulism* in children, with *night terrors*, the child starting upon a run as if pursued. Third \times trituration in 2 grain doses 3 times a day, the last at bedtime. The specific indications, according to Watkins (*Comp. of Ec. Med.*), are nervousness and apprehension, night terrors, sleep-walking, epilepsy. Two grains of 3 \times trituration every 3 hours.

AVENA SATIVA.—COMMON OAT.

The seed of the *Avena sativa*, Linné, and a farina prepared therefrom.

Nat. Ord.—Graminaceæ.

Botanical Source.—*Avena sativa*, or the common oat, has a smooth stem, from 2 to 4 feet high, with linear-lanceolate, veined, rough leaves, with loose, striate sheaths; the stipules are lacerate; the panicle equal and loose; the spikelets pedunculate, pendulous, 2-flowered, both flowers being perfect, the lower one mostly awned; the paleæ are somewhat cartilaginous, closely embracing the caryopsis; the root is fibrous and annual.

History.—Oats have been noticed by the ancient Greek and Roman writers; at present they are cultivated in nearly all northern temperate latitudes. Their native country is unknown, though they are stated to be indigenous in Sicily and in a certain Chilian island. When the seed is stripped of all its teguments, including its innermost, silky, fibrous covering it constitutes *groats*; and when this is ground into fine meal or flour it is called *prepared groats*. When the seed is kiln-dried, stripped of its husk and delicate outer skin, and then coarsely ground it constitutes the oatmeal of Scotland, a common, farinaceous article of food for laboring people and children (C.). Many forms of "rolled oats" are now a general article of commerce, forming excellent cereal foods. Oats are largely cultivated in America as food for horses and cattle. American oatmeal is said to be inferior to the foreign preparations.

Chemical Composition.—Vogel found oats to contain 66 per cent of meal and 34 per cent of husk; the dried meal consists of starch, 59; saccharo-mucilaginous extract, 10.75; albumen, 4.3; oleaginous matter, 2; ligneous fiber and moisture, 24 (T.—C.). Other analyses have been made, which vary from the above in quantity and elements, showing oats to consist of a large proportion of starch, some sugar, gum, oil, albumen, gluten, a nitrogenous body, epidermis, alkaline salts, etc. M. Payen found oats to contain starch, 60.59 parts; gluten and other azotized matters, 14.39; dextrin, glucose, or congenerous substances, 9.25; fatty matters, 5.50; cellulose, 7.06; silica, phosphates of calcium, magnesium, and soluble salts of potassium and sodium, 3.25 (P.). A large proportion of the nitrogenous material consists of *avenin*, a body containing a large proportion of nitrogen to a small amount of oxygen (about 17 to 1). With solvents it behaves much like *legumin*, which it resembles. It may be obtained from oatmeal by treating the latter, at a low temperature, with a dilute solution of caustic potash, decanting the clear liquid and precipitating the impure *avenin* by means of acetic acid. To purify it wash it first with diluted alcohol; then, with concentrated alcohol, dissolve again in a dilute solution of potassium hydroxide, and treat again with acetic acid, when *avenin* will be precipitated (Kreusler).

Oatmeal.—*AVENÆ FARINA*. Oatmeal is odorless, or has but little odor, is not so white as wheat flour, and has a somewhat bitterish taste. Particles of the integument may be observed in it, and it contains the gluten of the oat. Its starch-cells are polyhedral, having a checkered appearance, and are usually aggregated into ovoid or subspherical masses, easily separable under pressure. It is insoluble in alcohol, ether, and the oils; but the first two remove an oleo-resinous matter from it. Water removes its nourishing principles when boiled with it.

Action, Medical Uses, and Dosage.—I. *AVENÆ FARINA*. Oatmeal is nutritive and demulcent. Good in *habitual constipation*, but not in *dyspepsia* accompanied with acidity of the stomach. In the form of gruel, either salted or seasoned with sugar, honey, or the pulp of fruit, it is an agreeable nutritive during *convalescence from acute diseases*, in the *puerperal state* and in some *chronic diseases*. Oatmeal made into a cake with water, baked and browned like coffee, then pulverized and made into a coffee, or infusion, forms a drink which will allay nausea and check vomiting in a majority of cases when all other means fail, and used thus is very useful in *diarrhœa*, *dysentery*, *cholera morbus*, and *irritable conditions of the stomach*. One ounce of oatmeal in 2 quarts of water, boiled down to 1 quart and then strained, forms a very nutritive gruel. It may be rendered more palatable by the addition of vegetable acids, aromatics, sugar, prunes, raisins, etc.

II. *AVENA SATIVA*.—This plant is a nerve-tonic, stimulant, and antispasmodic. It ranks among the most important restoratives for conditions depending upon *nervous prostration*, and for the *nervous exhaustion* consequent upon *typhoid* and other low fevers, and the accidental disorders arising from these complaints, as *weak heart*, *spermatorrhœa*, *insomnia*, etc. In *enfeebled states of the heart muscle* it acts as a good tonic to improve the energy of the organ, and is recommended by Prof. Webster to prevent *relapsing cardiac rheumatism*. In this condition it is not thought to be specially antirheumatic, but rather to strengthen that debility upon which the rheumatic diathesis depends, so that the patient is less subject to atmospheric and other impressions. In *spermatorrhœa* it is adapted to those cases of debility following *adynamic diseases*, or in simple *spermatorrhœa* when not due to self-abuse. The atonic state gives rise to a nervous erethism or an enervated condition favorable to nocturnal losses. In cases depending wholly or partially upon prostatic irritation it is of less value, but aids *staphisagria*, *sabal*, *salix nigra* aments, and other indicated remedies. *Spasmodic conditions of the neck of the bladder* are said to be relieved by it.

A few years ago it was much lauded as a remedy to assist the morphine-consumer to throw off the habit, and to sustain the nervous system while undergoing that ordeal. We have, however, found it to exert but little good in this direction. A strong tincture may be prepared by crushing or pounding to a pulp the entire oat-plant when the grain is "in the milk," covering with strong alcohol and allowing it to macerate 14 days. The dose is from 10 to 30 drops in hot water; specific *avena*, 1 to 20 drops every 2 or 3 hours; Keith's concentrated tincture, 1 to 25 drops. This remedy was introduced by B. Keith & Co.

Specific Indications and Uses.—Nerve tonic, stimulant, and antispasmodic. Spasmodic and nervous disorders, with exhaustion; cardiac weakness; nervous debility of convalescence; spermatorrhœa from the nervous erethism of debility; tensive articular swellings.

AZEDARACH.—AZEDARACH.

The bark of the root of *Melia Azedarach*, Linné.

Nat. Ord.—Meliaceæ.

COMMON NAMES: *Pride of India, Pride of China, Bead-tree, Indian lilac, African lilac, and Persian lilac*, a name properly belonging to *Syringa persica*.

Botanical Source.—This elegant tree, attains the height of 30 or 40 feet, with a trunk about 1½ feet in diameter, and divaricate branches. The bark is rough. The leaves are alternate and unequally bipinnate; the leaflets opposite, ovate, acute, serrated, sometimes incised, and in pairs with an odd one. Lilac-colored flowers are borne in terminal panicles, on axillary peduncles. The corolla consists of 5 petals, patent, pale-pink inside, deep-lilac outside; the calyx is 5-parted. Stamens with tube 10-cleft at top, deep-violet; anthers yellow. Ovary 5-celled; stigma 5-lobed; style columnar. The fruit is a drupe the size of a small olive, with one 5-celled, bony nut; the cells are 1-seeded (L.).

History.—This tree, although a native of several Asiatic countries, is cultivated in the warm climates of Europe and America; it does not grow to any extent north of Virginia, and flowers early during the spring. Its name of *Bead-tree* was derived from the use to which its hard nuts are put in Roman Catholic countries, viz.: for making rosaries. The recent bark of the root is the most active part for medicinal purposes. It has a disagreeably bitter taste, and a very unpleasant odor, and imparts its properties to water at 100° C. (212° F.), and to weak alcohol. A fluid extract might possibly be prepared from it for general use. Quite a quantity of alcohol may be obtained from the berries by fermentation. This drug was early used by the Arabs and Persians. In the East the flowers and leaves are used locally to cure nervous headache, and a poultice of the flowers is employed to destroy lice and cure scalp eruptions. The fruit, though poisonous, is given in scrofula and leprosy (Dymock, *Mat. Med. Western India*).

Description.—The commercial bark comes in curved or irregular pieces, or quills, which break with a somewhat fibrous fracture. They vary considerably in length and thickness; are reddish-brown externally, with irregular ridges running lengthwise, of a blackish color. The inner surface also has longitudinal markings, and is either whitish or light-brown in color. It has a sweetish, succeeded by nauseous, bitter taste, and is without odor. The bark of old roots has a thick, corky layer, of a rust-color, which must be removed if a good article is desired. It has scarcely any taste.

Chemical Composition.—Jacobs, in 1879, obtained the bitter resinous constituent of this bark, of a yellow-white color. It dissolves readily in alcohol, chloroform, and ether, and is but partially soluble in carbon bisulphide, turpentine, benzin, and water; scarcely at all in the last three. Its other constituents are thought to be similar to those of the *Azadirachta indica* (see below).

Action, Medical Uses, and Dosage.—The bark is anthelmintic, and in large doses narcotic and emetic. Kollock states that if gathered in the spring of the year, during the ascent of the sap, it will cause narcotic symptoms resembling those occasioned sometimes by spigelia. Among the effects of over-doses are dizziness, dimness of vision, confusion of the mind, tendency to syncope, vomiting, stertorous respiration, coma, pupillary dilatation, cold perspiration, and catharsis. It is useful in *worm fevers* and in *infantile remittents*, in which, although worms are absent, yet the symptoms are similar to those accompanying the presence of worms. Dose of the powdered bark, 20 grains; of the decoction (which is the best form for administration, 2 ounces of the bark to 1 pint of water, and boiled to ½ pint), 1 tablespoonful every 1, 2, or 3 hours till the desired effect obtains; a purgative should follow its employment. The fruit is somewhat saccharine, and is said to be an active anthelmintic; its pulp has been used in an ointment for destroying lice and other ectozoa, as well as in the treatment of scald-head and other

diseases of the skin. By expressing the nuts an oil may be obtained which is said to possess anthelmintic properties, and to be useful as a local application to rheumatic affections, cramps, obstinate ulcers, etc. As an anthelmintic it has attained considerable reputation in our Southern States, where the bark may be obtained fresh.

Related Species.—*Melia Azadirachta*, Linné (*Azadirachta indica*, Jussieu). *Nim tree of India*, where it is cultivated extensively for medicinal use. The bark is a bitter, astringent tonic. The leaves are used in glandular enlargements, pustular, cutaneous diseases, and their juice as an anthelmintic. The fermented sap of the tree is employed as a stomachic. It is regarded reverentially by the superstitious natives, who believe that syphilis is cured by waving a nim branch in the air, and that the insane are cured by passing through an opening formed by reunion of the extremities of the parts of a cleft limb, or trunk of the tree. Hove found a decoction of the leaves useful in liver disorders and intermittents. The drug is official in the *Pharmacopœia of India* (see Dymock, *Mat. Med. of Western India*).

Margosa bark (*Nim bark*), as this drug is called, contains a substance considered as an alkaloid by Cornish (1856) and to which he gave the name *margosine*. It has a bitter taste, and was obtained only in exceedingly small amounts as a "double salt of margosine and soda," taking the form of long, white, acicular crystals (*Pharmacographia*). The composition of margosine and of *margosic acid*, obtained by the same experimenter from a bitter oil contained in the seeds, is unknown. Broughton (*Pharm. Jour.*, 1873) believed the bitter principle to reside in an amorphous resin having the formula $C_{25}H_{36}O_{11}$. He also obtained a crystalline principle of unknown character, which he, however, thought to be a fatty body, a view not participated in by Flückiger on account of its high melting point, 175° C. (347° F.) (*Pharmacographia*).

Melia dubia, Cav. India. The dried fruit is used by the poorer classes as a remedy for colic, the half of a fruit very effectually relieving the pain. The green fruit, with sulphur and curds, is employed in *scabies* (Dymock).

Soymida febrifuga, Jussieu (*Swietenia febrifuga*, Willdenow). *Nat. Ord.*: *Meliaceæ*. This is the *Rohuna* or *Rohun tree* of Hindustan, and is known on the Coromandel coast of India as *Redwood tree*, and is the only known species of the genus. The bark is very bitter and astringent, and was recommended by Roxburgh as a substitute for cinchona. It was admitted into the *Edinburgh Pharmacopœia* in 1803, and in 1807 into the *Dublin Pharmacopœia*. It is used as a tonic and also as an antiperiodic; but, according to Ainslie, if given beyond the extent of 4 or 5 drachms in 24 hours will derange the nervous system and occasion vertigo and subsequent stupor. It is said to have been employed in India with success in the treatment of *gangrene* (?); and in Great Britain as an astringent, and in the treatment of *typhus fever*. Waring, who has employed it, considers it to be a bitter tonic and not a febrifuge.

Swietenia Mahogani, Linné. *Mahogany tree*. West Indies, Mexico, and the American tropical region. Yields the well-known wood, mahogany. Bark bitter and astringent; contains catechin.

Kaya senegalensis, Guillemin et Perrottet. Bark and wood similar to preceding; contains an alkaloid (Caventou). Used in Africa in *intermittents*.

Carapa guianensis, Aublet, and *Carapa Touloucouna*, Guillemin et Perrottet. Bark anthelmintic; seeds yield crab, kundah, or callicoonah oil, which is non-volatile and bitter.

BALSAMUM PERUVIANUM (U. S. P.)—BALSAM OF PERU.

"A balsam obtained from *Toluisfera Pareiræ* (Royle), Baillon"—(U. S. P.). *Myrosperrum of Sonsonate*, Pareira; *Myrosperrum Pareiræ*, Royle; *Myrozydon Pareiræ*, Klotzsch; *Toluisfera Balsamum* var. Baillon.

Nat. Ord.—*Leguminosæ*.

COMMON NAMES: (Tree) *Peru balsam tree*; (Balsam) *Balsam of Peru*.

ILLUSTRATIONS: Köhler, *Med. Pflanzen Atlas*; Bentley and Trimen, *Med. Plants*, 83.

Botanical Source.—A beautiful tree much resembling the *Toluisfera Balsamum*, Miller, growing to a height of about 50 feet, the ramifications of its branches beginning low at a distance of from 7 to 10 feet from the ground and having both a spreading and ascending tendency. The young branches are covered with a smooth, gray, or purplish bark, beset with yellowish or white penticels. The alternate, petioled leaves are odd-pinnate, with from 7 to 11 leaflets. The leaf-stem, somewhat thickened at the base, and the base of the leaves are beset with a dense growth of very stout, yellow, reverse hairs. The leaflets are about 3 inches long and half as wide, lanceolate-ovate, rounded at base, pointed (the point being sometimes twisted), undulate, and folded at the edge. They are finely veined, and within the venation of the leaf-substance there occur more or less rounded or oblong, oil receptacles, transparent when held up to the light. The mid-rib is very prominent on the under-surface of the leaf. The flowers are numerous,

hermaphrodite, and long-peduncled, in slender racemes. The fruit is an oblan-ceolate, indehiscent legume, about 2 to 4 inches long, and contains one seed, the mesocarp of which exhibits balsam receptacles, especially two oblong vittæ upon each side.

History and Collection.—Until recent years it has generally been believed that the tree yielding Peru balsam was the *Myroxylon Peruiferum* of Linné filius, a tree growing along the western coast of South America and in Brazil. Pareira (1850), however, showed that another species produced it, and provisionally named that species the *Myrospermum of Sonsonate*. Some authors, like Baillon, Carson, Ruiz, and others, regard the trees furnishing the balsams of Peru and Tolu as identical. Others, however, regard them as entirely distinct from each other. Flückiger and Hanbury, in *Pharmacographia*, make the following distinctions:

“**M. TOLUIFERA:** Trunk tall and bare, branching at 40 to 60 feet from the ground, and forming a roundish crown of foliage. Calyx rather tubular. Racemes dense, 3 to 4½ inches long. Legume scarcely narrowed towards the stalk end.”

“**M. PAREIRÆ:** Trunk throwing off ascending branches at 6 to 10 feet from the ground. Calyx widely cup-shaped, shallow. Racemes loose, 6 to 7 inches long. Legumes much narrowed toward the stalk-end.”

The Peru balsam tree inhabits the coast region of San Salvador in Central America. While the trees are found singly or in clusters in the forests, they are generally owned by certain individuals who control the collection of the balsam, which is done by the natives. The trees are in the sections known as the Indian Reservation Lands of the Balsam Coast. The flowers are said to be so fragrant as to be smelled at a long distance, even before one is in sight of the trees.

Dr. Charles Dorat, of Sonsonate, in a letter to Mr. Daniel Hanbury, gives the following account of the collection of Balsam of Peru:

“Early in the month of November or December, or after the last rains, the balsam trees are beaten on four sides of their stems with the back of an ax, a hammer, or other blunt instrument until the bark is loosened, four intermediate strips being left untouched that the tree may not be injured for the next year. Five or six days after men with resinous torches or bundles of lighted wood apply heat to the beaten bark, which becomes charred. It is left eight days, during which the burnt pieces of bark either fall or are taken off. As soon as they perceive that the bare places are moist with the exuding balsam, which takes place in a few days, pieces of rag (of any kind or color) are placed so as entirely to cover the bare wood. As these become saturated with the balsam, which is of a light-yellowish color, they are collected and thrown into an earthenware boiler, three-quarters filled with water, and stirred and boiled gently until the rags appear nearly clean, and the now dark and heavy balsam sinks to the bottom. Fresh rags belonging to the same owner are continually being put into the boiler until sun-down, when the fire is extinguished; when cold the water in the boiler is poured off, and the impure balsam set aside. During this process the rags that appear to have been cleared of balsam are taken out of the boiler at different times and given to a man to be pressed, by which means much balsam is still obtained. The press consists of a small open bag about 14 inches long, made of stout rope fixed together with twine, open at the middle and looped at both ends to receive two sticks. The rags are placed inside, and the whole is twisted round by means of the sticks and the balsam thus squeezed out. A washerwoman wringing out a wet cloth fairly represents the process. The balsam thus procured is added to that in the boiler. The next day the cold balsam is weighed and put into *tecomates* or gourds of different sizes and sent to market” (extract from *Reprint, with additions from Pharm. Jour. and Trans.*, Dec., 1863, article on *Peru Balsam*, by Daniel Hanbury).

Balsam of Peru is so-called because it originally went to Europe from Peruvian ports, and was thought to be a product of the Peruvian tree above mentioned. It now enters commerce from Acapulco either in earthenware jars or in metal drums. The balsam of our markets is not constant in quality or appearance.

Description.—Balsam of Peru is “a liquid having a syrupy consistence, free from stringiness or stickiness, of a brownish-black color in bulk, reddish-brown

and transparent in thin layers, of an agreeable vanilla-like, somewhat smoky odor, and a bitter taste, leaving a persistent after-taste. On exposure to air it does not become hard. Specific gravity: 1.135 to 1.150 at 15° C. (59° F.). Miscible, in all proportions, with absolute alcohol, chloroform, or glacial acetic acid; only partially soluble in ether or benzin. It is completely soluble in 5 parts of alcohol. Water agitated with a portion of the balsam reddens blue litmus paper"—(U. S. P.). It is inflammable, burning with a fuliginous flame, and giving out an aromatic odor. It is miscible with water by means of mucilage.

Tests.—"If 1 Cc. of carbon disulphide be mixed with 3 Cc. of the balsam, contained in a dry test-tube, a clear liquid will result. On now adding 8 more Cc. of carbon disulphide and agitating the resinous constituent of the balsam (amounting to about 15 per cent) will adhere to the walls of the tube, and the liquid portion will be clear, of a tint not deeper than light-brownish, and not more than faintly fluorescent (absence of gurjun balsam). If 2 Cc. of the balsam be vigorously shaken in a dry test-tube with 8 Cc. of benzin, so that the balsam may be spread over the walls of the tube, and the liquid then immediately poured off, the balsam should remain adherent to the walls for some minutes and subside slowly, while the liquid (which should be filtered if turbid) should be colorless or only faintly yellow, and should deposit no sediment on standing (absence of appreciable quantities of storax, turpentine, copaiba, etc.). If 10 drops of the balsam be triturated in a small mortar with 20 drops of sulphuric acid, a tough, homogeneous, brownish-red mass will result, which, when washed with cold water, should, after a few minutes, be converted into a brittle, resinous mass (absence of fixed oils). On distilling water with a portion of the balsam no essential oil should pass over"—(U. S. P.). G. L. Ulex (*Jour. Pharm. and Trans.*, Vol. XII, p. 549, from *Archiv. der Pharmacie*, Jan., 1853) gives the following mode of detecting the purity of balsam of Peru: "To detect copaiba balsam, the substance is to be heated in a small tube retort until a few drops of a yellow, oily liquid have passed over, which takes place at a temperature of 190° C. (374° F.). This distillate is acid and soon deposits crystals of cinnamic acid. If the balsam was pure it solidifies completely, but when adulterated with copaiba the crystals float in copaiba oil. The distillate is then to be saturated with caustic potash, and the solution of cinnamate removed by means of blotting paper. The drops of oil which are then left mix quietly with iodine if the balsam was pure, but cause an immediate explosion if copaiba was present in it." Mr. W. J. Jenks gives the following simple method for detecting the *true* balsam of Peru from the false or adulterated: Place a drop or two of the article on the tongue, if it be true balsam it produces a liquid, diffused impression; if the false (a solution of resin), the resin is deposited on the tongue and on the back of the teeth" (*Amer. Jour. Pharm.*, 1867, p. 7).

Chemical Composition.—The chief constituent of this balsam appears to be *cinnamein* (*benzylic cinnamate*) ($C_9H_9[C_6H_5]O_2$). This, when treated with concentrated caustic alkalis, is resolved into *benzylic alcohol* (C_7H_9O) and *cinnamic acid*. The melting point of artificially-prepared cinnamein (Grimaux) is 39° C. (102.2° F.). Upon boiling it suffers decomposition.

According to the analyses of Kraut (1869) and Kachler (1870) the balsam contains, besides cinnamein, benzylic benzoate, benzoic and cinnamic acids, resin, and a small portion of benzylic alcohol, besides *stilbene*, found by Kraut alone. The resin (about 32 to 38 per cent) obtained as a residue by treatment with carbon disulphide is a "black, brittle, amorphous mass, having no longer the specific odor of the balsam" (*Pharmacographia*). By fusion with caustic potash Kachler (1869) obtained from it proto-catechuic acid; by destructive distillation toluol, styrol, and benzoic acid. *Benzylic benzoate* ($C_7H_9[C_6H_5]O_2$) is an oily, colorless substance, which boils near 340° C. (644° F.) and forms crystals at a much reduced temperature. *Benzylic alcohol* (*benzalcohol*) (C_7H_9O) is probably the so-called *peruvian* of Frémy in a purified condition. It is a colorless oil, feebly aromatic, boils at 204° C. (399.2° F.), and is not so light as water. It may be resolved into bitter almond oil, and subsequently into benzoic acid, by means of oxidizers. *Stilbene* is in the form of scales of a pearly luster, or in prismatic crystals, fusible, and boiling near 340° C. (674° F.). Its composition is $C_{14}H_{12}$. *Cinnamein* (*benzylic cinnamate*) is a brownish, aromatic fluid before purification and colorless when pure. It constitutes about 60 per cent of Peru balsam (Kachler). It is oily,

feebly and agreeably odorous, and to the taste sharp and aromatic. The difficulty of distilling it, even with superheated steam of 300°C . (572°F .) or above, renders its extraction by this method less easy than by evaporation from carbon disulphide (Flückiger). Its density is near 1.095. It is the body called by Stolze *Peru balsam oil*. The leaves of *Myroxylon Pareiræ* yield a fragrant oil (*Pharmacographia*). Vanillin was isolated from Peru balsam by E. Schmidt, in 1885. Delafontaine, in 1870, found *cinnamyl cinnamate* (*styracin*) ($\text{C}_9\text{H}_7\text{COO} [\text{C}_9\text{H}_7]$).

Action, Medical Uses, and Dosage.—This agent in medicinal doses occasions some cutaneous heat, increases the rapidity of the circulation, and augments the renal secretion, with irritation of the kidneys. Large doses, by producing gastro-intestinal irritation, may cause diarrhoea and vomiting. It should not be employed in febrile states. Balsam of Peru possesses expectorant and stimulating properties, acting more especially on mucous tissues, lessening their secretions when profuse. It is useful in all chronic affections of mucous tissues, as in *catarrh*, *gonorrhœa*, *mucous inflammation of the stomach and bowels*, *chronic diarrhoea* and *dysentery*, *leucorrhœa*, etc. Externally it forms an excellent application to *obstinate ulcers*, *wounds*, *ringworm of the scalp*, *eczema*, and other *cutaneous affections*. It may be applied alone, or in ointment made by melting it with an equal part, by weight, of tallow. It is much employed in Germany to destroy the *itch insect* and its eggs. After a warm bath the whole body is rubbed three times a day with 40 drops of the balsam. This is done for two days when the scabies is cured. It is considered antiseptic, and has recently been applied locally to *tuberculous ulcers*, involving the bones, larynx, and skin. Wounds are readily healed by it in parts lacking vitality. *Chilblains*, *sore nipples*, *pruritus vulvæ*, and *senile pruritus* are said to be promptly relieved by it. The dose is from 10 to 30 drops, and is best given diffused in water by means of sugar and the yolk of egg, or gum Arabic, or in alcoholic solution dispensed in glycerin. Used in ointment with beef's marrow, 1 ounce, sulphate of quinine 10 grains, balsam Peru 1 drachm, it forms an excellent tonic and stimulant preparation for *alopecia*.

Related Species.—*Myroxylon Peruvianum*, Linné filius (*Myroxylon pedicellatum*, Klotzsch; *Toluifera Peruviana*, Baillon). This is the tree that was formerly supposed to yield balsam of Peru. It is a large tree, with a thick, straight, smooth trunk; a coarse, gray, compact, heavy, granulated bark, of a pale, straw color, filled with resin, which, according to its quantity, changes the color to citron, yellow, red, or dark-chestnut; smell and taste grateful, balsamic, aromatic; leaves pinnated; leaflets alternate, of 2, 3, 4, or even 5 pairs, ovate-lanceolate, acute, coriaceous, somewhat emarginate at the apex, shining above, hairy on the underside, marked with transparent spots, terminal one the same size as the others; flowers in axillary racemes longer than the leaves; calyx campanulate, nearly equally 5-toothed, with the odd tooth remote from the others; petals 5, white; upper reflexed, broad, roundish, emarginate; the other four distinct, linear-lanceolate, reflexed, spreading; stamens 10, distinct, spreading, shorter than the petals; anthers mucronate; samaras pendulous, straw-colored, pedicellate, linear-oblong, about 2 inches in length, compressed, membranous, except at the apex, which is obliquely rounded, clavate, 1-celled, 1-seeded; seed reniform, lying in yellow liquid balsam, which hardens into resin (L).

The *Myroxylon Peruvianum* is common to the forests of Peru in low, warm, sunny situations near the river Marañon, and in other portions of South America, as New Granada, Brazil, Ecuador, and Bolivia, flowering from July to October. The resin, obtained in small quantities, resembles Peru balsam, except that it is harder and of a deeper-red tint. No crystals could be detected in it when pressed between two warm glass-plates (*Pharmacographia*). Its density is 1.031. It has an astringent, feebly-pungent, balsamic taste. With sulphuric acid it yields a sticky, grease-like mass, and not a brittle resinous body like Peru balsam. Both castor oil and alcohol dissolve it in any quantity, forming solutions which are clear.

BALSAMO BLANCO ("Balsamito" or "Balsamo católico or Virgin balsam") (*Pharmacographia*).—There is likewise a variety of Peruvian balsam of a pale-yellowish color, syrupy, becoming crystalline, highly fragrant (odor of melilot), and of a bitterish, acrid, somewhat aromatic taste. It is called *White Peruvian balsam*, and is obtained by expressing the fruit. It is of very fine quality, but is not prepared for market. Prismatic crystals of *myroxocarpin* ($\text{C}_{24}\text{H}_{36}\text{O}_3$), a neutral resin, were obtained from it by Stenhouse, in 1850. Dorat (letter to Hanbury) states that "from the flowers there is distilled a most delicious and fragrant *aguardiente*, far superior to any brandy." When dried this balsam constitutes the *Dry Peruvian balsam* or *Indian opobalsamum*, and is of a reddish, pulverizable, resinoid character. The fruit infused in rum is used for several medicinal purposes by the natives, also under the name of *balsamito*.

RESINOUS EXUDATE.—The *Myroxylon Pareiræ* exudes a natural resin, which, according to Dorat and others, is not aromatic, and which Attfield declares to be devoid of cinnamic acid. The latter found it to contain resin, uncrystallizable and feebly acid, 77.4; gum, similar to gum acacia, 17.1; limpid, fragrant, colorless, volatile oil and water, about 4.0; woody fiber, 1.5. It has no relation to the balsam, though obtained from the same tree.

BALSAMUM TOLUTANUM (U. S. P.)—BALSAM OF TOLU.

"A balsam obtained from *Toluiifera Balsamum*, Linné" (U. S. P.) (*Myroxylon Toluiifera*, Kunth; *Myrospermum Toluiiferum*, Richard; *Toluiifera Balsamum*, Miller).
Nat. Ord.—Leguminosæ.

COMMON NAMES: (Balsam) *Balsam of Tolu*, *Tolu balsam*; (tree) *Tolu balsam tree*.

ILLUSTRATIONS: Köhler, *Med. Pflanzen*; Bentley and Trimen, *Med. Plants*, p. 84.

Botanical Source.—This tree very closely resembles that yielding balsam of Peru. The trunk is tall and bare, and at about 40 to 60 feet from the ground throws out its branches, producing a rounded crown of foliage. The younger tree the larger the foliage of obovate leaflets, older trees suffering from the drainage of balsam. The flowers are borne in dense, axillary racemes, 3 to 4½ inches long, and the calyx tube is rather tubular. The fruit is an oblong, linear legume, scarcely narrowed at its base. The tree, which is an evergreen, rises to a height of 70 or 80 feet.

History.—As with the preceding article, so with the present, it has been involved in considerable obscurity, it formerly being uncertain whether the same trees which yield balsam of Peru furnished likewise that of Tolu. Some, notably Baillon, consider that the two balsams are derived from the same species, and that the method of gathering, etc., causes their dissimilarity. It is, we believe, now quite definitely settled that entirely distinct species furnish the two balsams. The *Toluiifera Balsamum*, which is undoubtedly the one species from which tolu is obtained, is found in many parts of South America, especially on the elevated plains and mountains near Carthagena, Tolu, and in the Magdalena province of Columbia. The balsam is said to be obtained by incisions made into the tree, from which it flows into wax (formerly) vessels placed for the purpose, and in which it solidifies. For the mode of procuring balsam of Tolu, see a paper by Mr. John Weir (*Lond. Pharm. Jour.*, 1864, and *Amer. Jour. Pharm.*, 1864, p. 449), summarized as follows by the authors of the *Pharmacographia*: "The balsam tree has an average height of 70 feet, with a straight trunk, generally rising to a height of 40 feet before it branches. The balsam is collected by cutting in the bark two deep, sloping notches, meeting at their lower ends in a sharp angle. Below this V-shaped cut the bark and wood is a little hollowed out, and a calabash of the size and shape of a deep tea-cup is fixed. This arrangement is repeated, so that as many as 20 calabashes may be seen on various parts of the same trunk. When the lower part has been too much wounded to give space for any fresh incisions, a rude scaffold is sometimes erected, and a new series of notches made higher up. The balsam-gatherer goes from time to time round the trees with a pair of bags of hide, slung over the back of a donkey, and empties into them the contents of the calabashes. In these bags the balsam is sent down to the ports, where it is transferred to the cylindrical tins in which it reaches Europe. The bleeding of the trees goes on for at least 8 months of the year, causing them ultimately to become much exhausted and thin in foliage" (*Pharmacographia*, 2d ed., p. 203).

Description and Tests.—Balsam of Tolu is imported from Carthagena in tin, earthen, and other vessels. When first received in this country it is soft and adhesive. As described by the U. S. P. it is "a yellowish-brown, semifluid or nearly solid mass, becoming more brittle when exposed to cold, transparent in thin layers, having an agreeable odor recalling that of vanilla, but distinct from it, and a mild, aromatic taste. Readily and completely soluble in alcohol, the solution showing an acid reaction with litmus paper. Also completely soluble in chloroform and in solutions of the fixed alkalies; almost completely soluble in ether, but nearly insoluble in water, benzin, or carbon disulphide"—(U. S. P.). It softens when chewed, melts when heated, and when burned evolves a fragrant odor.

Chemical Composition.—According to Frémy, Tolu balsam consists of cinnamoin, cinnamic acid, and resin, and the balsam resinifies to a crystalline mass with greater facility than the balsam of Peru. About 8 parts of volatile oil are obtained from 4000 parts of tolu by distillation with water; this oil contains *tolene* ($C_{10}H_8$), which is thin, colorless, and volatile, and has an acrid, hot taste and

a pleasant odor. Its density is 0.858. Oxygen is rapidly absorbed by this body. Benzoic acid, cinnamic acid, benzylic benzoate, and benzylic cinnamate are present in balsam of Tolu, the latter in larger proportion (Busse). *Vanillin* was also found in this balsam (E. Schmidt). Guibourt states that as the balsam solidifies its odor becomes more feeble, but its quantity of cinnamic acid is augmented, which is probably owing to the action of the atmosphere upon its oil effecting a chemical change. According to E. Kopp, the solid, resinous portion of the balsam consists of two resins which have the composition of hydroxides of styracin (see *Balsam of Peru*), one easily and the other difficultly soluble in alcohol. Deville, however, maintained that there is but one resinous body. Upon dry distillation, beside the above-mentioned acids and ethers, balsam of Tolu yields a hydrocarbon termed toluol (C_7H_8), styrol, and phenol. *Toluol*, or *toluene* (C_7H_8), is the body found among the products when wood, certain resins, and other vegetable substances are submitted to destructive distillation. It is likewise found in coal tar. Chemically it is *methyl-benzene* ($C_6H_5.CH_3$ or C_7H_8). It is a powerfully refractive, oily liquid devoid of color, and has a benzol-like odor. It boils at $111^\circ C.$ ($231.8^\circ F.$), and refuses to congeal at $-20^\circ C.$ ($-40^\circ F.$). Its density is 0.86.

Balsam of Tolu is scarcely soluble in the essential oils (*Pharmacographia*), but water at $100^\circ C.$ ($212^\circ F.$) takes up its *cinnamic acid*. It yields very little volatile oil when distilled with water, and if the distillation be continued its acid sublimes. Mr. Hatchett found that when he dissolved it in the smallest possible quantity of liquor potassæ, it completely lost its own odor and assumed a most fragrant smell, somewhat resembling that of the clove-pink (T.). "When balsam of Tolu is pressed between two warm plates of glass, so as to obtain it in a thin, even layer, and then examined with a lens, it exhibits an abundance of crystals of cinnamic acid" (*Pharmacographia*). Acetone and glacial acetic acid easily dissolve it, and it is insoluble in benzene. G. L. Ulex (*Pharm. Jour. and Trans.*, p. 550, Vol. XII, from *Archiv. der Pharmacie*, Jan., 1853) gives the following mode of testing the purity of balsam of Tolu: "Pure Tolu balsam, heated in sulphuric acid, dissolves without any disengagement of sulphurous acid, yielding a cherry-red liquid; when, however, colophony, with which it is frequently adulterated, is present, the substance blackens, swells up, and disengages much sulphurous acid." The same is true of turpentine. "Carbon disulphide, aided by a gentle heat, removes from the balsam scarcely anything but some of its cinnamic and benzoic acids. On decanting and evaporating the disulphide no substance having the properties of *resin* should remain"—(*U. S. P.*). Recently efforts have been made to distinguish between the different balsams, including Tolu and Peru balsams, and to recognize admixtures of resin, etc., by determining the saturation-power of the balsams for alkalies, and by similar methods (Kremel and Dieterich).

Action, Medical Uses, and Dosage.—Balsam of Tolu, like that of Peru, is a stimulant, tonic, and expectorant, and may be used as a substitute for it in *chronic catarrhs*, and other *pulmonary affections* not actively inflammatory in their character. It is usually preferred on account of its more agreeable flavor, and for which it is often added to cough-mixtures. The balsam, dissolved in ether, and the vapor therefrom inhaled, is reputed beneficial in *coughs* and *bronchial affections* of long standing. Two parts of Tolu, 3 of almond oil, 4 of gum Arabic, and 16 of rose water, make an excellent liniment for *excoriated nipples*. The dose is from 10 to 30 grains, frequently repeated, and given in tincture, syrup, or similar to balsam of Peru.

Related Species.—*Myroxylon punctatum*, Klotzsch (*Toluisera punctata*, Baillon; *Myropermum balsamiferum*, Ruiz et Pavon). This species grows in the northern portion of South America, and is known to the Peruvians as *Quino-quino*. Bentley, Trimen, and Flückiger, among others, regard it as identical with *Toluisera Balsamum*, Miller.

Bowdichia major.—Yields the hard, yellow, bitter bark, *Sucupira*; contains an alkaloid possessing mydriatic power (Petit). The Brazilians employ the bark in *rheumatism* and *fevers*.

BAPTISIA.—WILD INDIGO.

The root and leaves of *Baptisia tinctoria*, Robert Brown (*Sophora tinctoria*, Linné; *Podalyria tinctoria*, Michaux).

Vat. Ord.—Leguminosæ.

COMMON NAMES: *Wild indigo*, *Indigo weed*.

Botanical Source.—Wild indigo is a perennial plant having a stem from 2 to 3 feet high, glabrous and branching, yellowish-green in color, and studded with small black dots. The leaves are subsessile, 3-foliate-palmate; the leaflets small, roundish, or obovate, acute at base, very obtuse at apex, bluish-green in color, and turn black on drying. The stipules are setaceous and caducous. The flowers are bright yellow, few, and borne in small, loose, terminal racemes. The calyx is 4 or 5-toothed. Petals 5, stamens 10, and distinct. The fruit is a subglobose, bluish-black pod the size of a pea, on a stalk longer than the calyx, and contains several seeds.

Fig. 38.

Baptisia tinctoria.

History.—Wild indigo is an indigenous perennial, having the appearance of a shrub, growing all over the United States in woods and on hillsides. It thrives best on dry, poor soils, being seldom met with in alluviums and rich, loamy soils. In New England the young shoots, like asparagus and poke, are eaten for greens, and like the latter, if too far advanced in growth, act as a drastic cathartic. The plant blooms from June to September, and yields a blue dye, not unlike, but inferior, to indigo. Baptisia is familiarly known as wild indigo, indigo weed, horsefly weed, yellow broom, clover broom, rattle bush, and yellow indigo. The name baptisia is derived from the Greek *bapto* or *baptizo* (to dye, to color), the plant having formerly been used as a coloring agent.

Owing to the great number of antiseptic remedies that have been presented to the profession within the last few years, wild indigo, the favorite drug of this class with the early Eclectics, has fallen into unmerited neglect. Baptisia was mentioned early in the present century by Dr. James Thacher, in his *Dispensatory*, as a local remedy for gangrenous and other ill-conditioned sores due to debilitated conditions of the body. Still it received but little attention until the "Eclectic fathers," in their studies of indigenous plants, pronounced it a valuable drug. In the *Western Medical Reformer* for 1846, Prof. John King highly recommended it for its alterative and antiseptic properties. Prior to this (1837) it was used by Eclectic physicians in diarrhoea with offensive discharges and typhus (?) fever, scarlatina maligna and putrid sore throat.

Description.—Baptisia presents a root-head, giving off knotted branches, and numerous bent or curved roots about 18 to 20 inches in length and from $\frac{1}{4}$ to $\frac{1}{2}$ inch in thickness. Externally the bark is rather scaly or dotted with wart-like excrescences, and is brown in color. The root breaks with a tough, fibrous fracture, displaying a whitish interior. The bark is thick; the corky layer thick and brown; the woody portion strong and porous. The root is inodorous, and of a nauseous, somewhat acrid taste; its virtues appear to reside chiefly in the bark. Both the root and leaves are medicinal. When the whole plant or any portion of it is dried it becomes black, and yields a blue dye, inferior to indigo. Alcohol or water will take up its active properties; also chloroform, ether, and glycerin.

Chemical Composition.—Mr. B. L. Smedley found in the root gum, albumen, starch, a yellowish resin, and a crystalline substance, which he believed to be probably a new alkaloid (*Amer. Jour. Pharm.*, 1862, p. 310). This supposed alkaloid was, however, asserted by Mr. J. A. Weaver to be a calcium salt. Both Weaver (1871) and Dr. F. V. Greene (1879) found an alkaloid the chloride of which possessed a nauseous, acrid taste. This alkaloid, *baptisine* (*baptitoxine*), will not dissolve in chloroform, benzol, or benzin, but it is soluble in water, ether, and alcohol. It has an acrid taste, and is said to be actively poisonous. Later investigations by Von Schroeder (1885) show the existence of three active constituents in baptisia root. One of them is the above *baptisine*, to which he gives the name *baptitoxine*. The others are two glucosids, *baptisin* and *baptin*. The former is bitter, does not dissolve in water, and is indifferent, so far as its activity is concerned.

The other (*baptin*) is in the form of soluble, acicular crystals, and is laxative and cathartic. The glucosid *baptisin* should not be confounded with the "Eclectic concentration," BAPTISIN, described below. The active principles of baptisia root were recently investigated, in detail, by Dr. K. Gorter (*Arch. der Pharm.*, 1897). He isolated *baptisin*, a non-bitter and (to frogs) non-poisonous glucosid of the formula, $C_{12}H_{22}O_{11} + 9H_2O$, capable of splitting with diluted sulphuric acid into sugar and *baptigenin* ($C_{11}H_{19}O_6$). Baptisin melts at $240^{\circ}C.$ ($464^{\circ}F.$); is difficultly soluble in water and dilute alcohol; when cold easily soluble in glacial acetic acid. He furthermore isolated the alkaloid *baptitoxine*, which he found identical with *cytisine* ($C_{11}H_{14}N_2O$), the alkaloid of the unripe seeds of Laburnum (*Cytisus Laburnum*). Previously (1895) Plugge established the identity of Von Schroeder's baptitoxine, which he obtained from the seeds of baptisia with *cytisine*, hence *ulexine*, *sophorine*, *baptitoxine*, and *cytisine* all denote one and the same substance.

Action, Medical Uses, and Dosage.—To the taste baptisia is somewhat bitter, subacid, and subastringent. It increases the secretions of the glandular apparatus of the gastro-intestinal tract. Large doses are dangerous, acting as an emeto-cathartic. Sometimes this action is so violent as to produce gastro-enteritis. Large doses have caused an excessive flow of viscid saliva, ulceration of the pharynx, insomnia, restlessness, and ocular disturbances. It produces soft, mushy stools, accompanied by a sensation of soreness of the whole body. Small doses act as a laxative. Baptisia is an active and efficient hepatic, stimulating the liver and causing an increased biliary secretion. It loses much of its activity when dried or boiled. It is asserted that *baptitoxine* increases the respiratory movements, and in toxic doses kills by asphyxiation through paralysis of the respiratory centers.

Therapeutically baptisia is indicated in pathological conditions characterized by feeble vitality with tendency to disintegration of tissue. The keynote of this drug is *sepsis*, accompanied by dark or purplish discoloration of skin and mucous membranes. The appearance of the face is swollen, dusky, and expressionless—has the appearance of having been long exposed to cold. It is not the remedy for acute disease characterized by great activity, but rather for cases showing marked capillary feebleness, with tendency to ulceration—a condition of atony.

Baptisia was first employed as a dressing for all kinds of *ulcerations*, *malignant ulcers*, *sore mouth*, mercurial or otherwise, especially when accompanied by foul breath, loss of appetite, and general gastric disturbance. *Sore nipples*, *erysipelatosus*, *scrofulous*, and *syphilitic ulcers* were treated with a decoction of wild indigo. The greater the tendency to mortification, the more highly the remedy was valued. It controls irritable and painful *ulcers*, lessens their foul discharges, and overcomes putrescency.

Baptisia is of marked value in many forms of *malignant sore throat*. The dusky, leaden-colored, faucial ulcerations of *scarlatina* and *tonsillitis* point to this drug. *Diphtheria*, with swollen and enfeebled mucous membranes, with free secretion, appearing either dusky or blanched, and accompanied by sloughing, calls for baptisia. While the infusion is undoubtedly the best preparation of baptisia, it can not always be employed, for the dried plant is almost worthless, and the fresh herb not always easily procured. We depend upon specific baptisia, giving it internally in small doses, and applying it locally, diluted with water. *Putrid ulcerations* of the mucous membranes of the nasal passages are benefited by baptisia. The offensive breath, with turgidity of tissue, will indicate the drug.

All *typhoid conditions*, marked by the dusky appearance of skin and mucous tissues, are promptly benefited by this agent. *Typhoid dysentery*, with stools like "prune juice or meat washings," or dark, tar-like, fetid discharges, mixed with decomposed blood, yields to its kindly action. *Typhoid fever* with persistent diarrhoea, *typhoid pneumonia*, *typho-malarial fever*, as well as common *continued fever*, with the usual indications, call for baptisia. It is said to be valuable in *variola* and *cerebro-spinal meningitis*. In the *sore throat of variola* it is of great utility. *Septicæmia* following retained fragments of placenta after abortion has been promptly checked by this drug. In *fetid leucorrhœa* and *ulceration of cervix uteri*, especially with muco-purulent discharges, a douche of baptisia will be found beneficial. It acts as a gentle excitant and local tonic to the vessels implicated in the ulcerative process. It has been employed with good results in atonic varieties of

acute rheumatism. In *fetid discharges from the ears, etc.*, the infusion will be found efficient, if injected into the parts with a suitable syringe. The leaves applied in fomentations have discussed *tumors and swelling of the female breast, resembling scirrhus.* Webster suggests baptisia in *mania, dementia, and melancholia*, with stupor, in conditions characterized by drowsiness in typhoid states. Baptisia is an old and tried remedy, but will still repay further study.

Dose of the decoction—made by boiling 1 ounce of the powdered bark in 2 pints of water down to 1 pint—1 tablespoonful every 1, 2, or 4 hours, as required; if it purge, produce nausea, or a disagreeable relaxation of the nervous system lessen the dose, or omit its use entirely for a time; of the alcoholic extract, 1 to 4 grains every 2, 3, or 4 hours. The usual form of administration is as follows: *R Specific baptisia, gtt. xx; aqua, fl̄iiv. Mix. Sig.: Teaspoonful every ½ or 1 hour.* Indicated remedies may be given with or alternated with the above. Locally an infusion of the recent plant; or, *R Specific baptisia, fl̄ss; aqua, Oi. Mix. Sig.: Apply 2 or 3 times daily.* An ointment: *R Specific baptisia, fl̄gi; vaseline, ʒi. Mix. Sig.: Apply locally to inflamed tumors, chancres, buboes, and ulcers.*

Specific Indications and Uses.—The indications will be found to be *fulness of tissue*, with dusky, leaden, purplish, or livid discoloration; tendency to ulceration and decay; sepsis; typhoid conditions; enfeebled capillary circulation; color of skin effaced by pressure and returns slowly; patient's face swollen and bluish, appearing like one having been frozen, or long exposed to cold, fetid discharges, with atony, and gangrene.

Related Species.—*Baptisia alba*, Robert Brown. *Prairie indigo.* Plains of western United States and in rich soil from Virginia to Florida. This species has white flowers, and is said to possess similar properties to the *Baptisia tinctoria*, for which it has been used as a substitute.

Castella Nicholsonii.—Contains a resinous body named by Putegnat *amargosin*. Reputed antiseptic.

Derivative.—BAPTISIN, prepared similarly to aletrin, was once supposed to be the active principle of the plant, but it is a mixture containing a greater or less proportion of the active principles of baptisia. Baptisin is of a yellowish-brown color, a strong odor, similar to that of the powdered root, and of a rather bitter, not very disagreeable taste, persistent in its character. It is partially soluble in alcohol, but gives a precipitate on standing. "I have found it to exert a powerful influence on the glandular system in doses of from ¼ to ½ grain; if given in large doses it produces a very disagreeable prostration of the whole system. It is also an excellent application to *gangrenous and erysipelatous ulcerations, and malignant and fetid ulcerations of the cervix uteri.* Combined with extract of leptandra, resin of podophyllum, quinine, or resin of cimicifuga, in diseases where these agents are indicated, it will be found valuable in *typhus and typhoid fevers, dysentery, and all diseases of a typhoid character, when administered internally*" (Prof. King, in *Amer. Disp.*, 15th ed.).

BARI DIOXIDUM (U. S. P.)—BARIUM DIOXIDE.

FORMULA: BaO_2 . MOLECULAR WEIGHT: 168.82.

SYNONYM: *Barium peroxide.*

"Commercial, anhydrous barium dioxide. It should be kept in well-closed vessels"—(U. S. P.).

Preparation.—This preparation is formed when baryta (barium monoxide, BaO) is heated to redness in a current of dry oxygen. It usually contains silica, lime, and iron oxide, which substances consequently exist as impurities in peroxide of hydrogen prepared from commercial barium dioxide. Therefore, aside from other considerations, it is better to use hydrated dioxide of barium to prepare this compound (see below).

Description.—"A heavy, grayish-white, or pale yellowish-white, amorphous, coarse powder, odorless and tasteless. When exposed to the air it slowly attracts moisture and carbon dioxide, and is gradually decomposed. Almost insoluble in cold water, with which, however, it forms a definite hydrate, and to which it imparts a decidedly alkaline reaction. Hydrochloric, phosphoric, and most other mineral acids, decompose it, producing the corresponding barium salts and hydrogen dioxide, which remains in solution for a considerable time, if the reaction has taken place in the cold, and an excess of the acid is present. When heated to a

bright-red heat barium dioxide fuses, loses oxygen, and is reduced to barium oxide. Barium dioxide should be dissolved by diluted hydrochloric or phosphoric acid without leaving more than a trace of residue"—(U. S. P.).

Tests.—"If 2.11 Gm. of barium dioxide be dissolved as completely as possible in ice-cold water to the volume of 25 Cc., with the aid of 7.5 Cc. of phosphoric acid, and 5 Cc. of this solution (corresponding to 0.422 Gm. of the dioxide) be measured off for assay, it should require not less than 40 Cc. of decinormal potassium permanganate V.S. to impart to the liquid a permanent pink tint, corresponding to not less than 80 per cent of pure barium dioxide (each cubic centimeter of the volumetric solution indicating 2 per cent of the latter)"—(U. S. P.).

Uses.—This salt is used for preparing the official solution of dioxide (peroxide) of hydrogen.

Barium and Its Compounds.—**BARIUM.** Symbol: Ba. Atomic Weight: 136.8. Barium is the metallic basis of the alkaline earth *baryta* (barium monoxide, BaO). It occurs, in nature, in the form of *heavy spar* (barium sulphate, BaSO₄) and as *witherite* (barium carbonate, BaCO₃), from which minerals it is chiefly obtained. It was isolated by Sir Humphrey Davy in 1808. It is also contained, to some extent, in certain mineral waters and in sea-water, feldspathic rocks, some silicates, and several manganese ores. It is a solid metal of a lustrous, silvery color, melts at a temperature below redness, and is not volatilized by a heat capable of melting plate glass, but at that temperature it acts violently upon the glass, probably decomposing its alkali. Exposed to the air it rapidly tarnishes, absorbs oxygen, and is converted into baryta or barytes. It sinks rapidly in water, decomposes it with great rapidity, hydrogen being evolved, and is converted into baryta. When strongly pressed it becomes flat and appears to be both ductile and malleable. All of the soluble barium salts are powerfully poisonous. They are antidoted by sulphate of sodium (Glauber's salt), sulphate of magnesium (Epsom salts), and sulphate of aluminum.

HYDRATED DIOXIDE OF BARIUM (BaO₂ + 8H₂O) is made as follows: Add powdered barium dioxide gradually to diluted hydrochloric acid until the acid is nearly neutralized; cool, filter, and add cautiously baryta-water until the silica and metallic oxides cease to separate and the white hydrated barium dioxide appears; then filter and add concentrated baryta-water until a precipitate ceases to form. Collect the precipitate upon a filtering-paper, wash with cold water, and preserve in well-corked bottles. It is used for the preparation of hydrogen dioxide, but otherwise is not employed in medicine.

BARIUM HYDROXIDUM.—*Barium hydrate* (Ba[OH]₂). Molecular Weight: 170.82. *Barium hydrate*, also called *heavy earth*, "*terra ponderosa*," is hydroxide of barium, and is formed when barium has been put into water. It was discovered, in 1774, by Scheele. It may be procured from the native sulphate of barium or ponderous spar, by mixing this in very fine powder with one-eighth its weight of powdered charcoal, keeping it at a red-heat for some time in a crucible; dissolving the sulphide of barium thus formed in nitric acid, filtering the solution, which is a nitrate of barium, sulphur being deposited, and slowly evaporating the filtered liquid till it crystallizes. Place the crystals of nitrate of barium in a crucible, and drive off the nitric acid by a strong heat gradually applied, whereby caustic baryta (BaO) is formed. Caustic baryta is a grayish-white, porous body, having an acrid, alkaline taste, no smell, an alkaline reaction, and when taken into the stomach proves a most violent poison. Its specific gravity is 4.5. In the air it attracts moisture, swells with heat, and falls to a white powder. It slakes with water like quicklime, forming the above hydrate; and water dissolves .06 part its weight of barium hydroxide, forming the test reagent for sulphuric and carbonic acids, known by the name of *baryta-water*. It forms several salts used in medicine and pharmacy. It should not effervesce upon the addition of acids.

BARIUM CARBONAS (BaCO₃). Molecular Weight: 196.85. *Carbonate of barium*, *Baryta carbonica*. Also called *witherite* after Withering, who first found it native in 1783, though previously examined by Bergmann. It is found in Hungary, Sicily, Siberia, Neuberg in Styria, etc., but occurs in considerable quantity in veins along with lead ore in different parts of England, and is found also in Scotland and in the Scandinavian Peninsula. It may be prepared artificially by exposing baryta-water to the air, or by passing carbonic acid gas into it; in either case the carbonate precipitates in the state of a white powder. The native carbonate occurs in masses, stalactitic, and crystallized in six-sided prisms formed by the intersection of three primary, right-rhombic prisms. It is poisonous, has no sensible taste, and when native has the specific gravity, 4.331; when artificial it scarcely exceeds from 4.23 to 4.30. Cold water dissolves $\frac{1}{111}$ part, and boiling water $\frac{1}{111}$ part of this salt; it is unalterable in the air, and when exposed to a blow-pipe heat it fuses, evolving much light, losing carbonic acid gas, and presenting the appearance of white enamel. It is dissolved or acted upon by the mineral acids with effervescence. Its principal use is in the preparation of barium chloride. It was formerly employed in *parasitic skin diseases*. Weakness of the legs, paralysis, and death have been produced by it. Webster declares it is a superior remedy for *acute parenchymatous tonsillitis*, to control the vascular disturbance and avert the formation of pus. Used early he claims it is abortive; less valuable in chronic cases. Homœopathic dilution (6 x), in 5 to 10-drop doses every 3 hours, in acute cases; 3 or 4 times a day, in chronic cases. *Specific Indications:* Scudder's indications are, "Weight and pressure about the pubes; scanty menstruation; very sensitive to cold; 2 x to 6 x trituration, $\frac{1}{4}$ to 1 grain."

BARI CHLORIDUM ($\text{BaCl}_2 + 2\text{H}_2\text{O}$). Molecular Weight: 243.5. *Chloride of barium.* This salt is easily obtained by dissolving carbonate of barium in diluted hydrochloric acid, evaporating the solution, so that on cooling crystals may form. Or it may be prepared by mixing powdered sulphate of barium with one-fourth its weight of charcoal, heating the mixture in a covered crucible for three hours at a low, white heat, powdering the product, stirring it well with 15 parts of water, boiling, filtering, and adding to the filtered liquor hydrochloric acid in small portions at a time until effervescence ceases, and the solution is neutral to test paper; again filter, evaporate, and set aside for crystallization. In this latter process be careful not to inhale any of the hydrogen sulphide gas which escapes on the addition of the hydrochloric acid. Chloride of barium forms transparent, right-rhombic, tabular crystals, generally flattened at the corners, odorless, of an unpleasant, sharp, amarus taste, permanent in the air, soluble in $2\frac{1}{2}$ parts of cold and $1\frac{1}{2}$ of boiling water, insoluble in strong alcohol, and of specific gravity, 3.06. When heated they lose their water of crystallization, and at a red heat fuse to a clear liquid. If the salt attracts moisture from the air it contains chloride of calcium; this is proved by shaking the finely-powdered salt with absolute alcohol, which dissolves any chloride of calcium or strontium present, filtering, evaporating the filtrate, treating the residue with water, and then with diluted sulphuric acid; a precipitate denotes strontium; this is filtered off, and after saturating the filtrate with ammonia, oxalate of ammonium is added, and any turbidity caused by it is due to calcium salts. The solution of chloride of barium must be so thoroughly precipitated by sulphuric acid as to yield no residue on evaporation; should there be a permanent one on heating, it is due to impurities. A blue precipitate with ferrocyanide of potassium denotes iron; with ammonia a white precipitate, disappearing on the addition of sal ammoniac, denotes magnesia, the chloride of which, like that of calcium, deliquesces in the air, and may also be a cause of the moisture of the chloride of barium. A blue color caused by the ammonia arises from copper. Chloride of barium is incompatible with the alkaline and metallic sulphates, the phosphates and carbonates. In large doses this salt is a violent poison, affecting the nervous system chiefly. Vomiting and purging, with abdominal pain, collapse, with extremely weak and thready pulse, labored breathing, with effusion into the bronchiae, muscular weakness, coma, and death, preceded by convulsions, are the toxic phenomena. In small doses it is said to be useful in *scrofula*, *dropsy*, *scirrhus affections*, *bronchocoele*, etc. It is used in solution, both externally and internally, 1 part of the chloride being dissolved in 8 parts of distilled water, and administered in doses of 10 drops, 2 or 3 times a day, gradually and carefully increased until nausea or giddiness is experienced. It has been used as a lotion in *herpetic eruptions*, and as a collyrium in *scrofulous ophthalmia* but its external use must be conducted with caution, as it is easily absorbed. It has lately (1889) been proposed as a heart stimulant, to increasing force, rhythm, and volume of the circulation. The dose for this purpose is $\frac{1}{4}$ grain. When taken in poisonous doses its antidotes are the sulphates, as sulphate of magnesium, with a free use of well or spring water, and evacuating the stomach as soon as possible, together with other treatment indicated by the symptoms present.

Chloride of barium, in solution, is employed as a test for sulphuric acid or the sulphates in solution, with which it forms a white precipitate of sulphate of barium (see *Test Solutions*), insoluble in mineral acids, except strong sulphuric acid.

Liquor Barii Chloridum of the U. S. P. (1870), was prepared by dissolving 1 troy ounce of barium chloride in 3 fluid ounces of distilled water (see *Test Solutions*).

Specific Indications and Uses.—Prof. Scudder (*Spec. Med.*) says of barium chloride: "In its action upon the economy this remedy has some resemblance to arsenic, and is indicated by an inelastic, dirty skin, enlarged lymphatics, and feeble respiration. It has been employed as a remedy in *cancer*, *scrofula*, and *scrofulous phthisis*. It has been deemed of especial value in *scrofulous inflammation of eyes, ears, and testes*." A teaspoonful of the dilution of 10 drops of the U. S. P. (1870) solution in 4 fluid ounces of water may be given every 3 or 4 hours, or 2 or 3 grains of the 3 x trituration may be employed.

BARI NITRAS ($\text{Ba}(\text{NO}_3)_2$). Molecular Weight: 260.58. *Nitrate of barium.*—This salt was known immediately after the discovery of baryta, and may be prepared by dissolving native carbonate of barium in nitric acid; or by decomposing sulphide of barium by means of nitric acid, filtering, evaporating, and crystallizing. It crystallizes in transparent, permanent octahedra and tetrahedra, is odorless, of a pungent and slightly bitter taste, soluble in 14 parts of water at 15.5°C . (60°F .), in 3 parts of boiling water, and slightly soluble in alcohol. Heat fuses it, with decrepitation; a strong heat drives off the nitric acid, and leaves pure barium monoxide. Firework makers use it to communicate a beautiful, green tinge to flame. It is employed in chemistry and pharmacy, in solution, as a test for sulphuric acid and sulphates, instead of the chloride of barium, when it is considered desirable to avoid the presence of a metallic chloride. The solution is made by dissolving one part of the nitrate in 20 parts of distilled water, and keeping the solution in well-closed bottles.

BARI IODIDUM ($\text{BaI}_2 + 2\text{H}_2\text{O}$). Molecular Weight: 425.88. *Iodide of barium.*—This salt may be obtained by dissolving carbonate of barium in hydriodic acid or by Magendie's formula: Take iodine, 100 parts; iron filings, 30 parts; water a sufficient quantity; form an iodide of iron, to which add a solution of barium hydroxide, 1 part, in distilled water, 20 parts, and continue it as long as a precipitate occurs; heat for a few seconds, filter the solution, concentrate by evaporation, and crystallize. It crystallizes in fine, acicular prisms, which are very soluble in water, and but feebly deliquescent. When long exposed to the air, a portion of the hydriodic acid is decomposed and dissipated, carbonate of barium is formed, and hydriodate of barium, colored by iodine, may be dissolved by water. It is a violent poison, requiring great caution in its use. Jahn recommended it as a powerful alterative, resolvent, and liqueficient, in *scrofulous enlargements*, *hypertrophy*, etc. The dose is $\frac{1}{2}$ of a grain, very cautiously

increased to 1 grain, 3 times daily, dissolved in distilled water. As an application to *scrofulous tumors*, Blett recommended an ointment, made by triturating 2 grains of the iodide of barium with $\frac{1}{4}$ ounce of lard; applied by friction. *Specific Indications and Uses:* Tonsillar enlargement; scrofulous lymphatic enlargements, scrofulous ophthalmia, with swelling of meibomian glands (Webster); testicular swelling and indurations; 3 x trituration, 2 or 3 grains, 3 times a day.

BARII BROMIDUM ($\text{BaBr}_2 + 2\text{H}_2\text{O}$). Molecular Weight: 332.34. *Bromide of barium.*—This salt occurs in rhombic, plate-like crystals, colorless, having an unpleasant taste, and dissolving freely in both alcohol and water. It is prepared from a hydrobromic acid solution of barium carbonate.

BARII SULPHAS (BaSO_4). Molecular Weight: 232.62. *Sulphate of barium, Heavy spar.*—This salt was discovered by Scheele in 1774; its nature was first ascertained by Assessor Gahn. It occurs in considerable quantity, chiefly in veins, and very frequently accompanies galena and gray copper ore; it is also frequently prepared artificially. It often occurs in right-rhombic prisms. Its color is white or flesh-red; it is brittle, commonly in plates, of specific gravity 4.41 to 4.67, odorless, tasteless; is not easily fused; is insoluble in nitric acid, and requires 43,000 times its weight of water at 16.5°C . (60°F) to dissolve it. Heated suddenly it decrepitates; a violent heat converts it into a white, opaque globule. Ignited in powder with charcoal it becomes changed into sulphide of barium, evolving hydrogen sulphide on the addition of hydrochloric acid, and forming a solution of chloride of barium. The several salts of barium are generally prepared from it. This material is extensively employed as an adulterant, or at least a substitute, of white lead, and the artificial salt especially, is consumed in enormous quantities for this purpose by painters, to whom it is known as *baryta* or *barytes*. This must not be confounded with monoxide of barium, which is also known as *baryta*.

BEBERINÆ SULPHAS.—BEBERINE SULPHATE.

SYNONYMS: *Beberizæ sulphas, Sulphate of bibirine, Sulphate of bebeerine.*

Source.—An impure sulphate of an alkaloid obtained from nectandra or bebeeru barks. The salt is probably a mixture of *beberine*, *nectandrine* (this is probably identical with *sipirine*), and other alkaloidal bodies.

Preparation.—The process for obtaining it is essentially the same as that for sulphate of quinine. The bark is at first freed of tannin and coloring matter by boiling it with carbonate of sodium; it is then exhausted by boiling in water acidulated with sulphuric acid, and the alkaloidal matter is thrown down from the concentrated acid liquor by means of carbonate of sodium. The impure bases thus separated are washed, dissolved, and neutralized with weak sulphuric acid, and the solution is treated with animal charcoal, concentrated, filtered again, and finally evaporated in thin layers in flat vessels. Any excess of acid must be carefully avoided, otherwise the salt will be charred on evaporating it to dryness.

Description and History.—The sulphate of beberine of commerce contains both bebeerine and probably *sipirine* (*sipeerin*), another alkaloidal principle also discovered by Dr. Rodie. It occurs in thin, somewhat glittering scales of a deep-brownish color (sometimes with a greenish tinge), and forming a yellow powder. It is inodorous, and has an intensely bitter, persistent, and somewhat astringent taste. Like the sulphate of quinine, it requires an excess of acid for its perfect solution; hence the addition of a few drops of diluted sulphuric acid renders its solution more complete. It is also soluble in alcohol. When well prepared the scale-like particles should be glittering and translucent, and when incinerated ought to leave no ash, or a mere trace only. In this way sulphate of calcium, the only important impurity which has been found in it, may be easily detected. When carefully dried it contains 90.83 per cent of base and 9.17 of sulphuric acid. Beberine sulphate is always impure, containing, as above stated, other alkaloids. While it has not been proven that nectandrine and sipirine are identical, it is altogether probable that they are one and the same. The commercial sulphate of beberine contains scarcely "one-third of its weight of the pure alkaloid" (*Pharmacographia*). (See *Nectandra*, *Buxus*, and *Pareira Brava*.)

Action, Medical Uses, and Dosage.—Beberine (and its sulphate) is a tonic and antiperiodic, and is applicable to the same forms of disease as those in which quinine is employed. It increases the appetite, raises the pulse a little, and improves the tone of the constitution generally, with but little tendency to produce ringing in the ears, headache, vertigo, or other nervous symptoms, as is the case with quinine, except when given in large or frequently-repeated doses. It has been used with success in *intermittent* and *remittent fevers*, but is inferior to quinine,

although a valuable substitute for it. It has been found of decided benefit in *periodic headache* and other *periodic neuralgias*, as well as in *atonic dyspepsia* and *general debility*. It seems to be specially applicable to persons of a strumous or phthisical habit, and in the latter stages of *phthisis* has strengthened the system, improved the appetite, and checked *night-sweats*. In *menorrhagia*, *strumous ophthalmia*, and in *pregnancy* requiring tonic treatment it has been highly prized by many practitioners. Dr. Scudder (*Spec. Med.*) asserted its specific action upon the uterus, and suggested its use in *menorrhagia*, where the flow is profuse and too frequent. The dose he suggested was from $\frac{1}{2}$ to 3 grains every 3 or 4 hours. The dose of sulphate of bebeerine is from 1 to 3 grains as a tonic and from 5 to 20 as a febrifuge. It may be given in pill with conserve of roses, or in solution. Half a drachm of the sulphate, 25 minims of elixir vitriol, a fluid ounce each of syrup and tincture of orange peel, and 4 fluid ounces of water, mixed together, form an excellent solution for general tonic purposes; of this a tablespoonful may be given 3 times a day, each dose containing about $2\frac{1}{2}$ grains of the salt. Dose of the salt, from 2 to 5 grains.

BELÆ FRUCTUS.—BAEL FRUIT.

The unripe or half-ripe fruit of *Ægle Marmelos*, Correa.

Nat. Ord.—*Aurantiaceæ*.

COMMON NAMES: *Bèl*, *Bael fruit*, *Indian quince*, *Indian bael*, *Bengal quince*.

Botanical Source.—A large, erect, thorny tree, with a few spreading branches. The leaves are ternate, with crenulate, lance-oblong leaflets, which are dotted to some extent. The terminal leaflet is the largest. The flowers are borne in both small, axillary and terminal panicles, and are quite large and of a white color. The fruit is a hard-shelled, subglobular berry.

History.—This tree abounds in Farther India and Hindustan. It is regarded as a sacred tree by the Hindus, who cultivate it largely in their gardens, and employ the leaves in enormous quantities in Siva worship. Sanskrit poems allude to it as an emblem of fruitfulness and increase, and to destroy it is sacrilege (Dymock). Several parts of the plant are used by the natives, but in England only the partially-ripe fruit is employed. It is official in both the *Pharmacopœia of India* and the *British Pharmacopœia*. From the ripe fruit a kind of thick sherbet is prepared, which, in India, is much esteemed as a laxative. Bael fruit, or Indian quince, is known in Indian vernacular as *bèl*, *bhel*, and *bela*. The fruit resembles the orange in appearance, has a delicious flavor and pleasant odor when ripe. The thick rind of the unripe fruit is astringent, and is used in India for dysentery, diarrhœa, and other bowel complaints. A yellow dye is prepared from the rind when the fruit is ripe.

Description.—The fruit, which has a hard, ligneous, almost smooth rind, is about the size of an orange, and is subglobular in shape. It is divided into from 10 to 15 cells, containing from 5 to 10 wooly seeds, immersed in a tenacious, transparent mucus. In commerce it appears as dried slices, more or less twisted, or in dried fragments of the pulp and seeds, with portions of the rind adherent. The rind is hard, nearly smooth, light-brown or gray in color; the pulp is brittle, yet firm, externally orange-brown or bright red, but on fracture exhibits a nearly colorless interior. It is without odor, and to the taste is mucilaginous, slightly astringent, and scarcely acid. When fresh, however, the fruit has a pleasant flavor, and the rind is aromatic.

Mangosteen, the fruit of *Garcinia Mangostana*, has been substituted in England as an adulterant.

Chemical Composition.—Bael fruit yields its properties to water, either by decoction or maceration. The chemical properties of this substance do not seem to be definitely understood. The pulp yields mucilage and pectin to cold water. Pollock reports tannin in the fruit, and according to Collas about 5 per cent of tannin may be obtained from the ripe fruit. Prof. Flückiger, however, states that neither the higher nor lower salts of iron show any appreciable amount of tannin in the infusion of the fruit. Warden, on the contrary, observes that when both the unripe and ripe fruits are moistened with ferric

chloride solution a marked reaction takes place, showing the presence of tannic acid in considerable quantity. This change was most noticeable in the pulpy portions nearest the rind. He also found that acid properties were possessed by the mucilage around the seeds, and that the same also contained calcium (Dymock).

Medical Properties and Uses.—In Malabar the root, bark, and leaves of this plant have refrigerant properties attributed to them, and are considered of great value in *hypochondria*, *melancholia*, *palpitation of the heart*, and in *asthma*. The ripe fruit is very agreeable to the taste, and is used for the removal of *habitual constipation*. A fluid extract of the rind of the unripe fruit may be given in *diarrhœa* and in *dysentery* in doses of from 30 minims to 2 fluid drachms every 2 or 3 hours.

Related Drug.—*Feronia elephantum*, Correa. *Wood apple*, *Elephant apple*. India. Used like bael for *diarrhœa* and *dysentery*. The ripe fruit is employed in *gum* and *throat affections*. The leaves have an odor like anise and are carminative. Externally applied the pulp and dried rind are employed for the *bites of poisonous insects*. A gum obtained from it is substituted for gum Arabic in India, and is used in *intestinal diseases* to overcome *tenesmus*. The ripe fruit is edible (Dymock). Citric acid in considerable amount may be obtained from the dried fruit.

BELLADONNA.—BELLADONNA.

I. BELLADONNÆ FOLIA (U. S. P.), *Belladonna Leaves*.—"The leaves of *Atropa Belladonna*, Linné"—(U. S. P.).

II. BELLADONNÆ RADIX (U. S. P.), *Belladonna Root*.—"The root of *Atropa Belladonna*, Linné"—(U. S. P.).

Nat. Ord.—Solanaceæ.

COMMON NAMES: *Deadly nightshade*, *Dwale*, *Black cherry*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, p. 193.

Botanical Source.—*Atropa Belladonna* is a perennial herb, with a thick, branched, fleshy, creeping root, and annual, erect, round, dichotomously branched, leafy, slightly downy stems, about 3 feet high. The leaves are lateral, mostly two together, of unequal size, ovate, acute, entire, soft, of a dull-green color, smooth and borne on short petioles. The flowers are imperfectly axillary, solitary, stalked, large, drooping, dark, dull-purple in the border, paler downward. The calyx is green, 5-parted, permanent, and nearly equal. The corolla is campanulate, with a short tube, and limb divided into 5, shallow, nearly equal segments. Stamens 5; filaments nearly as long as the corolla tube; anthers cordate and 4-lobed; stigma capitate and 2-lobed. The fruit is a 2-celled, many-seeded berry, subtended by the enlarged calyx; it contains reniform seeds (L.—Smith). When bruised the whole plant exhales a fetid odor.

Fig. 39.

Flowering branch and fresh root of *Atropa Belladonna*.

History.—This plant is common to Europe, growing among ruins and in waste places, blossoming from May to August, and maturing its berries in September. It is also found as far east as Central Asia. It is often found growing in woodlands, and especially in the woods of high elevations, as of mountains. It is cultivated to some extent in this country, in France, and in Britain. The whole plant possesses poisonous properties. The leaves must be gathered while the plant is in flower. The *British Pharmacopœia* directs the leaves (gathered at the beginning of the fruiting season and separated from the stems, and dried with care) of the wild or cultivated plants growing in Britain. The British or imported dried German root is directed under *Belladonnæ Radix*. Leaves in as fresh a state as possible should be employed, as the older leaves are said to absorb

moisture, causing decomposition of the active constituents, with the liberation of ammonia. The stems should be rejected, also musty leaves, if the herb is desired for the preparation of the alkaloids, or if a full-strength preparation is desired. The root should be taken up in the spring, or late autumn, from plants at least three years old.

Description.—The *U. S. P.* demands belladonna leaves and root conforming to the following description:

BELLADONNÆ FOLIA (*U. S. P.*), *Belladonna Leaves*.—"Leaves from 10 to 15 Cm. (4 to 6 inches) long, from 5 to 10 Cm. (2 to 4 inches) broad, broadly ovate, equilaterally narrowed into a petiole, tapering at the apex, entire on the margin, smooth, thin, the upper surface brownish-green, the lower surface grayish-green, both surfaces whitish punctate; odor slight; taste bitterish, disagreeable"—(*U. S. P.*).

BELLADONNÆ RADIX (*U. S. P.*), *Belladonna Root*.—"In cylindrical, somewhat tapering, longitudinally-wrinkled pieces, 10 to 25 Mm. ($\frac{3}{8}$ to 1 inch) or more in thickness; externally brownish-gray, internally whitish; fracture nearly smooth and mealy, not radiating or showing medullary rays in the thicker roots, only in the layer near the bark; nearly inodorous; taste sweetish, afterward bitterish, and strongly acrid. Roots which are tough and woody, breaking with a splintery fracture, should be rejected; likewise the hollow stem-bases which are sometimes present"—(*U. S. P.*).

From "*Belladonna*," edited by F. B. Kilmer, of Johnson & Johnson, we abstract, by permission, as follows:*

BELLADONNA LEAVES.—*Macroscopically*: "Belladonna leaves are of two sizes, the larger about 1½ d. m. long, the smaller being about one-half this size. They

Fig. 40.

- k. Crystal-containing cells (calcium oxalate in minute crystals).
- l. Simple trichome.
- d. Head-bearing and gland-bearing trichome.

are brownish-green upon the upper surface and gray-green below, broadly ovate or ovate-long, narrowed into a petiole; apex acute or acuminate; margin entire, the petioles and nerves of the underside of the leaf particularly are downy, hairy, and glandulous. Both surfaces of the leaf possess trichomes, numerous cells are apparent, filled with crystal-like contents, giving the leaf the peculiar spotted appearance it possesses. The leaf is membranaceous, odor narcotic, and taste bitter and disagreeable.

Microscopically: "The epidermal cells, on making a surface section, appear undulating. On the under surface the stomata are more numerous, near to which arise trichomes, which tend to cover and protect the stomata by preventing too great evaporation and so assist the work of transpiration. The hairs are of three kinds: (a) Simple-jointed cells; (b) short, glandular cells, with one or more (3 to 4) celled apex; (c) hairs with long stalks and a spherical-celled apex. In the mesophyll are cells containing an innumerable number of granule-like or crystal-like bodies.

Belladonna Leaves of the Market: "As found in the market, belladonna leaves, especially the finer grades, when crumpled or broken up, look very much like the mints, but are easily distinguished from them by the narcotic odor and disagreeably bitter taste. They also resemble somewhat the narcotic herbs, stramonium and hyoscyamus, but from these may be easily distinguished.

"Belladonna leaves, compared to the other official leaves of the *Solanaceæ*, are comparatively smooth and the margin is entire. The upper surface is darker than the lower surface. The undeveloped fruit, a calyx with an unripe berry, is often present.

*This monograph contains contributions from the pens of Profs. Henry Kraemer, Charles Rice, John M. Malach, J. U. Lloyd, J. F. Remington, R. G. Eccles, M. D., H. C. Wood, M. D., W. C. Caldwell, M. D., John B. Smith, A. R. L. Dohme, Robert W. Johnson, and others.

"Stramonium leaves are dark-green and not quite so smooth as belladonna, the hairs shorter, with a many-celled apex, and in the mesophyll are numerous cells containing large, single crystals of calcium oxalate. The perforations and cork formations in the leaves are numerous. The base of the leaf is unequal and does not taper into a petiole. The fruit is a capsule, and very often a few reniform seeds will be found present.

"Hyoscyamus leaves are furnished with long hairs, which tend to become tangled and matted, so giving the leaf a hairy appearance. There is an absence of petiole and a presence of stem-stalks. The fruit is a pyxis enclosed in an urn-shaped calyx. The seeds are much smaller than stramonium.

"Solanum nigrum leaves are much smaller than belladonna, with a repand dentate margin (Wigand).

BELLADONNA ROOT.—*Macroscopic characters.* "The root of belladonna is a fleshy, spindle-shaped, primary root. When fresh it is about 5 decimeters long, and about 5 centimeters in diameter. It then possesses a number of stout branches, the remnants of which are sometimes seen attached to pieces of commercial root. The bark contains the largest amount of alkaloid, therefore roots are selected by careful buyers which possess the larger portion of bark compared to the woody portion. Young roots of but 2 or 3 years are preferred. Chemical analysis shows that the amount of alkaloid in roots collected about the time of flowering is twice as much as in spring, so roots should be collected about the flowering and fruiting season, carefully dried and preserved.

"The commercial root, to hasten the drying, is invariably split into smaller pieces. It occurs in rough, irregular pieces, from a few inches in length to 6, 8, or even 12 and 15 inches, varying in diameter according as the root is split. Externally, it is longitudinally wrinkled, of a pale-brown, or grayish color; internally, brownish, or whitish; odor heavy and licorice-like; taste peculiar, characteristic, sweet at first, and afterward acrid or bitter. The fracture may be mealy, horn-like, or woody, and from these characters may be distinguished 3 commercial varieties:

1. *Mealy Belladonna.*—"Is lighter externally and internally than the other two, and on cross-section it is of a nearly uniform, dirty-white appearance. The bark is about $\frac{1}{4}$ of the cross-section. At the periphery of the fundamental tissue of the pith are yellowish, vascular bundles scattered apparently indiscriminately. These finally disappear beyond the cambium. Starch is present throughout all the cells of the wood and bark, which is colored blue by iodine. In spring and autumn roots the starch is present in the largest amount.

2. *Horn-like Belladonna.*—"Is very dark. On cross-section it looks brownish and waxy, or horn-like. The bark is

separated by an indistinct cambium from the woody portion, of which the fibro-vascular bundles are arranged in single groups, and separated from each other by one or more broad bands of a horn-like tissue (keratrenchym). In the tissues of both the wood and bark occur numerous cells filled with crystal-like contents, appearing to the eye as white spots. This variety looks more like inula root, and is much smaller generally than the other two. The starch grains are replaced by a dark, resinous material.

3. *Woody Belladonna.*—"This form possesses characters between the other two. The color is more of a light-brown or gray. In cross-section the bark resembles the horn-like

variety. Inside of the cambium ring is found a prominent, radiating, woody zone, with the largest duct in the very center. The wood bundles have prominent, yellow ducts, and are separated by equally prominent, broad medullary rays. This variety is generally figured in text-books. Starch grains are not so numerous as in the mealy variety, still they are abundant.

Microscopically.—"The cork consists of thin layer of cells, next to which is arranged the cortex. In the latter are numerous cells filled with crystal particles, called by Wigand *krystallmehl*, and by Moeller *krystallsand*. These are very common characteristics in both the roots and the leaves of bella-

donna. The sieve tubes are scarcely perceptible in the bark of young roots, but later are formed in groups more or less wedge-shaped like the wood bundles. These sieve tubes show a beautiful sieve plate in longitudinal section. Stone cells are wanting. As regards the bast in belladonna authors disagree. Wigand (4th ed., 1887) mentions the presence of bast. Prof. Schrenck announced in the *American Druggist* (1887, p. 2) that he had detected bast cells in belladonna root, but found it necessary to remove the starch and stain the cells. The writer examined a mount made by Prof. Schrenck from the belladonna root of commerce (October 16, 1886) mounted in glycerin jelly, and stained apparently with phloroglucin, and readily made out bast cells. Upon further investigation he found it unnecessary to use clearing and staining agents to discover them. The ducts are provided with elliptical pores. The wood bundles are surrounded by wood parenchyma (colored yellow by potassium hydroxide solution), the bundles separated from each other by radially broad, medullary rays. Both the wood and bast parenchyma contain starch. The starch grains are of medium size, in shape round, irregular or hemispherical, or even 2 or 3-sided; single and sometimes compounded of 2 or 4 starch grains. Some of the grains possess a distinct cross-cleft or a stone-like nucleus; in others, however, the stratifications are scarcely apparent. With sulphuric acid alone large numbers of prismatic crystals are produced. With sulphuric acid and bichromate of potassium a greenish coloration is immediately produced, remaining sometimes 24 hours or more."

Chemical Composition.—The chief and most interesting constituent of belladonna is the alkaloid *atropine* ($C_{17}H_{23}NO_3$) (see *Atropina*), first obtained in crystalline condition from the root by Mein and from the herb by Geiger and Hesse (*Pharmacographia*). On the history and constituents of this plant Mr. Kilmer, the editor of "*Belladonna*" (Johnson & Johnson), offers the following data herewith:

"Galen is the first author who refers unquestionably to the mydriatic action of two species of Solanaceæ. Dr. Ray, in 1686, reported the case of a lady who had placed a belladonna leaf upon a small ulcer beneath the eye and afterwards was annoyed by an excessive dilatation of the pupil. Evers independently, in 1773, discovered the mydriatic power of belladonna. These writers were followed by Davies (1775) and Loder (1796). After this the specific action of belladonna upon the eye became generally accepted. Runge, in 1819, approximately isolated the alkaloid of hyoscyamus and called it *koromegyn* (meaning magnifier of pupil). In 1830 the apothecary Mein isolated the alkaloid atropine from the root. Independently Geiger and Hesse, in 1832, isolated the crystallized alkaloid from the herb, while Liebig, in 1833, determined its chemical formula."

The main constituents of belladonna are as follows: *Atropine* ($C_{17}H_{23}NO_3$) (see *Atropina*). *Hyoscyamine* ($C_{17}H_{23}NO_3$), sometimes the principal constituent of belladonna root. It is convertible into atropine by heat; conversion also takes place in the plant itself. *Atropamine* ($C_{17}H_{23}NO_3$) is identical with the *apoatropine* obtained by Pesci, in 1882, by the action of nitric acid upon atropine (O. Hesse, 1893). It is convertible into *belladonnine* by the action of HCl or KOH. *Belladonnine* ($C_{17}H_{21}NO_2$) (Hübschmann) is an amorphous alkaloid, and is obtainable from hyoscyamine or atropine by heating these alkaloids from 120° to 130° C. (248° to 266° F) for several hours. By raising the temperature gradually, transformation takes place with products resulting in the following order: Hyoscyamine, atropine, atropamine, and belladonnine. *Hyoscyne* ($C_{17}H_{21}NO_4$), discovered by Ladenburg in *Hyoscyamus niger*, occurs in belladonna root in small amounts (Schuette, 1892). O. Hesse, in 1893, showed its identity with *scopolamine*, an alkaloid obtained from the root of *Scopolia atropoides*, B. and P. (*S. carniolica*, for which E. Schmidt, in 1892, had found the formula, $C_{17}H_{21}NO_4$). Earlier analyses show the presence in belladonna of *chrysotrophic acid* (Kunz), the concentrated solutions of which show green and blue fluorescence, *atrosin*, a red-coloring principle in the root (Hübschmann), succinic acid in the herb, malates, and oxalates, combined with sodium, potassium and magnesium salts, gum, wax, asparagin, chlorophyll (in the leaves), starch, and albuminous bodies.

The Production of Atropine in the Plant.—"Messrs. Schering, in 1888, stated that belladonna roots contain practically only hyoscyamine, and that atropine was a decomposition product produced during the process of manufacture. Drs. Will and Schmidt (1887) proved that the mere contact of an alkali with hyoscyamine was sufficient to produce this change. Dr. Schuette (*Arch. der Pharm.*, 1891, p. 492) found that the same result is produced by repeated crystallization from acidulated water. He also investigated the influence that age and period of vegetation exerted upon alkaloids in the roots, leaves, and berries. He found that fresh roots (1 to 2 years old), collected from a basaltic district, whether gathered in the spring, summer, or autumn, contained only hyoscyamine, but the older roots (8 years and upwards) always contained, besides much hyoscyamine, a little already-formed atropine. Similar results were obtained with roots from old cultivated plants that had been kept for several years. Spring and autumn leaves of belladonna contained principally hyoscyamine, with equal quantities of ready-formed atropine. The unripe berries of the wild plant contained chiefly hyoscyamine and a little atropine, but the ripe fruit contained only atropine. The ripe berries of cultivated plants, however, yielded both hyoscyamine and atropine. His investigations upon other members of the Solanaceæ indicated that hyoscyamine is the primary base from which other alkaloidal products may be formed."

Conclusions.—"Regarding the time of collecting and variation of alkaloid in the plant, investigators have drawn the following conclusions:

"The first year's growth of belladonna contains but one-half the quantity of atropine present in older plants, and so are unworthy of collection. Young roots contain only hyoscyamine. The older roots contain both hyoscyamine and atropine, the latter predominating. In young leaves atropine is present, but hyoscyamine is the predominating alkaloid. The length of keeping after gathering appears to have no influence on the alkaloid present (Maisch). From the second to the fourth year the quantity of alkaloid is fairly uniform. At these ages, and during the period of flowering, the plants should be collected. The plant before flowering, is not rich in active principle, but at the period of flowering the full development is reached and maintained, both in roots and leaves (Gerrard). Wild-grown belladonna contains a larger quantity of alkaloid than the cultivated kind. The process of flowering and leafing does not exhaust the root of its alkaloid, there being a simultaneous development in the root and leaf; therefore the roots may be gathered at the same time as the leaf.

"Gerrard's analysis of the freshly-gathered plant shows the highest percentage of alkaloid in the leaves; following them the root, fruit, and stem, and the wild plant contains the largest amounts of alkaloids. Later investigators, however, have shown that the root will show a much higher average. The results of analysis of the commercial dry root and leaf of belladonna indicate that the roots

yield a much higher percentage of alkaloid than the leaves (.82 per cent has been found). A chalky soil favors the formation of atropine, which may account, to some extent, for the superiority of the English leaf. Belladonna leaves in pressed packages several years old do not show evidence of loss of alkaloids (Lyons). Both the root and leaf of belladonna show great variations in strength, and, as has been said, appearance alone is not a sufficient criterion as to the relative value of one lot as compared with another. The peculiar acid and acrid taste of belladonna, which is more apparent as the sense of taste is cultivated, together with general physical characters already described, are fair indications to an expert of the value of a sample of belladonna. Chemical analysis is, however, the only certain and reliable test as to the full value"—(*Belladonna*).

Action and Toxicology.—Belladonna is an energetic, narcotic poison. While fatal to carnivorous animals and to man, the same doses have but relatively little effect upon fowls and herbivora. Dogs, however, stand relatively large amounts of this drug and its alkaloid. Children are often poisoned by the berries, mistaking them for cherries. In large doses, according to Pereira, it acts upon the cerebro-spinal system, as manifested by the symptoms, "dilatation of the pupils (mydriasis), presbyopia, or long-sightedness with obscurity of vision, or absolute blindness (amaurosis), visual illusions (phantasms), suffused eyes, occasionally disturbance of hearing (as ringing in the ears, etc.), numbness of the face, confusion of head, giddiness, and delirium. The mouth and throat become dry, with difficulty of deglutition and articulation, constriction about the throat, nausea, vomiting, swelling, and redness of the face, and sometimes irritation of the urinary organs, or an exanthematous eruption." If the dose be very large, the above-named symptoms will be produced, but in a more violent form, with extravagant delirium, followed by sopor. Convulsions are rarely present; when it causes death it is commonly by coma. The effects of belladonna and atropine are practically identical. Therefore, for further remarks concerning the action of this drug, see *ATROPINÆ SULPHAS*.

The proper remedies in poisoning by belladonna are the stomach-pump, emetics and purgatives, cold to the head; and in the comatose stage, ammonia internally, with external stimulants, electro-magnetism, etc. (C.) Belladonna and opium appear to exert antagonistic influences, especially as regards their action on the brain, the spinal cord, and heart; they have consequently been recommended and employed as antidotes to each other in cases of poisoning; this matter is now positively and satisfactorily settled; hence in all cases of poisoning by belladonna the great remedy is morphine, and its use may be guided by the degree of pupillary contraction it occasions. Bouchardat and Suiz Rioya recommend iodine as an antidote, even when the symptoms of poisoning with belladonna are of long duration; the compound solution of iodine may be given for this purpose.

Medical Uses and Dosage.—Therapeutically employed belladonna exerts precisely opposite effects from those of its toxic doses. Large doses paralyze, small doses stimulate, the nervous system. Belladonna, as chiefly used in our school, is selected in conditions in which there is *impairment of the capillary circulation* in any part of the body, *with congestion*.

Dr. J. Harley, from a series of experiments instituted by himself, was led to consider belladonna: 1. As a direct and powerful stimulant to the sympathetic nervous system, or to the heart, being superior to all agents in its simple, direct, immediate, and powerful influence in exalting the force and rapidity of the heart's action, and therefore useful in cases where there is a depression of the sympathetic nervous influence, as in *syncope* from *asthenia* or *shock*; in the *collapse of cholera*; in *failure of the heart's action from chloroform*, or other cardiac paralyzers. 2. As a diuretic in cases of suppression of urine, whether accompanied by uremic symptoms or not. He has likewise found it efficient in *acute nephritis*, in which it calms the nervous irritation, and at the same time contracts the dilated blood-vessels; in *chronic albuminuria*, in which it stimulates the kidneys to healthy action, and diminishes the albumen gradually. He also considers it useful in *rheumatic fever* and in the *uric and lactic acid diathesis*. According to Prof. Brown-Sequard, belladonna diminishes the blood in the spinal cord, and hence diminishes the vital properties of it and its nerves; dilates the pupil, causes the secretion

of milk to cease; is useful in *strangulated hernia*, *nocturnal incontinence of urine*, etc. It has a depressant influence upon the pneumogastric nerve, excites the sympathetic, depresses the cerebro-spinal system, touches the secretions, and is slightly aperient. It imparts tone to most involuntary muscles, causes wakefulness, restlessness, is a powerful excitant of the blood-vessels, and in large doses causes delirium; it is useful in external *neuralgia*, in *congestive headache*, and *coma*, with contracted pupil, in *paraplegia*, with symptoms of irritation of the motor, sensitive and vaso-motor or nutritive nerve-fibers of the spinal cord, or of the roots of its nerves, as in *spinal congestion*, *meningitis*, *myelitis*, etc. It is a dangerous agent in *paraplegia*, without symptoms of irritation, as in cases of white softening, or of the reflex paraplegia.

Prof. J. M. Scudder, who based his investigations upon the experiments of Brown-Sequard, and to whom we are indebted for the chief indications for the use of belladonna, employed it to relieve congestion of the nerve-centers, in which malady he considered it a specific wherever there is an enfeebled circulation in the cerebro-spinal centers, as manifested by enfeebled innervation, sluggish circulation, tendency to coma, and to congestion of internal organs, a soft, oppressed pulse, dilated pupils, pasty, soft skin, coldness of the extremities, and involuntary micturition, acting by causing contraction of the blood-vessels of the spinal cord and the capillary blood-vessels, and which action may be effected by stimulation through the sympathetic nervous system. He adds from 5 to 10 minims of specific belladonna to 4 fluid ounces of water, of which the dose is a fluid drachm every 1, 2, or 3 hours, according to the symptoms and influence of the agent (see *Diseases of Children*). In doses large enough to dilate the pupil it exerts an opposite influence, and then becomes useless as a remedy, and fails to produce its specific action. The indications for this agent as a specific are a full, oppressed pulse, tendency to congestion, diminished heat of parts distant from the heart, a labored, slow, and imperfect respiration, expressionless countenance, dullness, hebetude, sleeping with the eyes partly open, drowsiness, dilated or immobile pupil, and coma. A deep color pervades the skin—a duskiness often—which, when the finger is drawn over it, is effaced, leaving a persistent, white streak, the blood very slowly returning. This is one of its best indications in the severer exanthemata. Involuntary urination and copious passages of limpid urine are also indications for its use; also deep aching in loins or back, with a feeling of fullness. When much pain is present, it may be combined with specific aconite. We employ minute doses of belladonna with confidence in congestive disorders. Throbbing, *congestive*, or *nervo-congestive headaches* are quickly relieved by it; or it may be a dull, heavy headache, with a drowsy feeling, as if, were it not for the pain, the patient would drop off to sleep. While it is a remedy for blood stasis, due to dilated capillaries in any part, its operation is perhaps more pronounced in impairment of circulation in the nerve-centers. In *cerebral or spinal congestion*, as evidenced by dullness and coma, it is the first remedy to be selected. In *chronic brain diseases*, with dizziness, drowsiness, and dull, heavy aching, with a sense of fullness in the head, its effects are pronounced, and when the dull eye, with dilated pupil and drowsiness, are present in threatened *apoplexy* this remedy should be selected.

Perhaps with no remedy is the size of dose so important as with belladonna. For the above-mentioned conditions and those similar to follow the proportions above mentioned are preferred. Webster, however, calls attention to the fact that the 3 x dilution (fl̄ss to fl̄j; aqua, fl̄iv. Teaspoonful every two or three hours) serves better in certain nervous disorders. The condition in which he uses belladonna in these attenuated doses is in "nervous exaltation—great irritability and impressionableness of all the senses." Such a condition accompanying spasmodic disorders—*chorea* and *epilepsy*—indicates it, while in *febrile disorders*, where the "hyperæsthesia of the senses amounts to delirium," he declares it the remedy. According to this author, wild and furious delirium is met by the attenuations; dullness and hebetude by the larger doses above-mentioned, keeping within the bounds indicated by Prof. Scudder.

Belladonna is one of the most important remedies for bladder and kidney diseases. It stimulates and at the same time relieves irritation of the urinary tract. Both the solid and watery constituents of the urine are increased in amount. It is the remedy in *urinal incontinence* in small children when the fault depends upon

a poor pelvic circulation or chronic irritability of the bladder (Locke). Should the latter condition result from rectal ascarides *santonine* will correct the trouble. It seems best adapted to that dribbling of urine in the young, which occurs chiefly during the day. We have seen marked benefit from minute doses of belladonna in children who urinate every twenty minutes or half hour, marked pallor of countenance and dullness of eye being present, and the condition evidently depending upon "a cold." *Diabetes insipidus* is well treated by applying a belladonna plaster and administering the drug internally. It is the remedy in the congestive and early stages of *kidney disease*, with a sense of fullness, weight, and dragging in the loins. *Tubular nephritis* (early stage), *scarlatinal nephritis*, and all cases of *renal capillary engorgement* are promptly benefited by belladonna. Belladonna is well known to cause dryness of the mouth, and in full doses it checks salivation, especially in that salivary overactivity accompanying *pregnancy*. Full doses likewise check the *exhaustive sweating of phthisis* and other debilitating diseases. Its good effects in this direction, however, are overbalanced by the dry condition of the mouth and fauces produced.

Belladonna is a remedy for *pain* and for *spasm*. Certain forms of *neuralgia*, particularly *trigeminal neuralgia*, are relieved by ordinary doses of belladonna. *Intercostal, visceral, and sciatic neuralgias* are sometimes amenable to it. If there be excitation of the circulation and increase of temperature *aconite* should be given with it. It overcomes spasm of the involuntary, but is less effectual in spasm of the voluntary, muscles. *Spasm of the anus, biliary spasm, uterine, cystic, intestinal and urethral spasms*, and *spasm of the ureters* are relieved by it. Such of these parts as can be reached should be treated locally with the extract. It is a remedy for *spasmodic asthma, whooping-cough*, and *nervous cough* from laryngeal irritation. In whooping-cough it is usually indicated in the latter stage, where it lessens the severity of the paroxysms and increases the intervals between them (Locke). *Obstinate constipation, spasmodic colic, lead colic, spasmodic constriction of the intestine, and spasmodic dysmenorrhœa* are conditions often met with belladonna. It is often serviceable in *chorea* and in *epilepsy*, with congestion. It is also recommended in *infantile convulsions* of an epileptiform character. *Hay fever* is said to be palliated by belladonna, and its influence is good in *spermatorrhœa*, with enfeebled pelvic circulation. It is useful, but less valuable than morphine, in *puerperal convulsions*. In various forms of *sore throat* belladonna is an important remedy. In *non-diphtheritic faucial inflammation*, with redness, swelling, soreness, difficult deglutition, with dryness of the throat and more or less fever, it should be administered in alternation with *aconite* every half hour. If given early it often greatly benefits in *diphtheria*, interfering with the formation of the membrane. In *non-vesicular erysipelas*, with burning and deep redness of the skin, where the subcutaneous tissues are not much involved, it is an efficient remedy.

Perhaps in no class of diseases has the action of belladonna been appreciated more than in the *exanthemata*. That it is a prophylactic, in minute doses, against *scarlatina* has long been maintained. On the other hand this view has been vehemently assailed. Whether true or not, and testimony is mainly in its favor, it certainly can do no harm, and if scarlet fever supervenes an advantage will have been gained in its early administration. In both *scarlet fever* and *measles* it is nearly always indicated, and its effects are certain and prompt. The more congestive the form the more satisfactory the effects from this remedy. It awakens the little patient from his stupid or drowsy state, or even from unconsciousness, quiets delirium, and favors the eruption and renal activity. Undoubtedly it also possesses some power over the poison producing the disease. *Urticaria* and *erythema* are often relieved by it, and it is a remedy in all *febrile states tending to congestion*. It is particularly a child's remedy, but must be cautiously used. We have observed the scarlatinoid rash from very minute doses of specific belladonna.

Belladonna is valued in the complications attending or following *scarlatina*. It readily relieves these troubles and tends to prevent sequelæ. Small doses of the specific medicine should be administered every hour.

The antagonism of belladonna and opium now seems well established, both physiologically and clinically. It is therefore, like atropine, used as an antidote to *opium* and *morphine narcosis*, as well as for the toxic action of *physostigma* and its alkaloid, *eserine* (*physostigmine*). Here it must not be used to over-stimulation,

for its narcotic effects are to be avoided. Small and oft-repeated doses of belladonna (or atropine hypodermatically) should be given until respiration becomes stronger, the pulse more forcible, and pupillary dilatation begins. Here the action should be maintained until the danger is past.

Externally it was formerly applied in extract to the parts around the eye, to dilate the pupil, before operating for *cataract*, in *iridectomy*, to relieve *internal ocular pressure* in *ulceration of the cornea*, and also in *iritis* to prevent adhesions. For these purposes a drop or two of an aqueous solution of the extract is sometimes placed upon the conjunctiva. The sulphate of atropine has now superseded the use of the extract. Both locally and internally belladonna is a prompt agent for the relief of *photophobia*. The ointment, or extract, has also been applied locally in *spasmodic stricture of the urethra*, and of the sphincters of the bladder and rectum, in *great pain along the female urethra*, in *strangulated hernia*, *spasmodic contraction of the uterus*, *hemorrhoids*, etc. Belladonna plasters, or the extract with vaseline, are applied to relieve pain in forming *abscesses*, *recurrent boils*, *neuralgia*, and *lumbago*, with gratifying results. No remedy is of more value to check the *secretion of the mammary gland* when prompt action is desired. One part of the specific may be added to 3 parts of glycerin, and the breast painted with it once or twice a day. Care should be had to see that the surface is unbroken or constitutional effects will be produced. A belladonna plaster over the heart relieves pain in that organ. The following has been recommended in *neuralgia of the uterus*: Mix together $1\frac{1}{2}$ grain of alcoholic extract of belladonna and $\frac{1}{2}$ of a grain of opium. Place the two extracts in the center of a little pledget of carded cotton, and fold it up so as to inclose the extract; tie it up with a very strong thread, and leave a double thread 8 inches long attached to it. The plug is to be introduced into the vagina by the physician or patient, and placed upon the neck of the uterus, where it is to be retained from 12 to 24 hours. In very *painful menstruation*, accompanied by *leucorrhœa*, from 8 to 15 grains of tannic acid, or extract of geranium, may be added to the tampon.

Belladonna is said to retard *schirrous growths*, and when applied to *cancerous tumors* it relieves pain. It is a remedy for *local or external inflammation*, *acute mastitis*, *inflammatory glandular swelling*, *sympathetic buboes*, *gouty* and *rheumatic inflammations*, etc. Apply the belladonna plaster.

Dose of the powdered leaves, 1 to 2 grains once or twice a day, and gradually increased till the peculiar effects of the medicine are produced; of the extract, $\frac{1}{4}$ of a grain to 1 grain; tincture of belladonna, 1 to 7 minims; fluid extract of belladonna, 1 to 2 minims; specific belladonna, gtt. v to x; to aqua, $\mathfrak{z}\text{iv}$. Teaspoonful every 1 to 3 hours for congestive states and general uses; for nervous disorders, with furious delirium, specific belladonna (3 x dilution), $\mathfrak{z}\text{ss}$ to $\mathfrak{z}\text{i}$; to aqua, $\mathfrak{f}\mathfrak{z}\text{v}$. A teaspoonful every 2 or 3 hours.

Specific Indications and Uses.—Dull, expressionless face, dilated or immobile pupils, dullness of intellect, impaired capillary circulation of skin or internal organs; drowsiness, with inability to sleep on account of pain; cold extremities, dusky, bluish face and extremities; skin soft, doughy, or pasty; circulation sluggish, with soft, full, oppressed, and compressible pulse; slow, labored, and imperfect breathing; sleeping with eyes partially open; hebetude; coma; urinal incontinence; copious passages of limpid urine; deep aching in loins or back, with sense of fullness. The remedy for congestion, with dilated capillaries; a deep redness of the skin, effaced by the finger, leaving a white streak, the blood slowly returning to the part; spasm of the involuntary muscles. In 3 x attenuation the remedy for nervous excitation, with wild and furious delirium; also in pallid countenance, with frequent urination.

Related Species and Adulterants.—I. *Adulterations or Admixtures of Root*: "JAPANESE BELLADONNA (*Scopolia Japonica*, Maximowicz) is a rhizome from 5 to 10 d. m. in length, and on an average 1 d. m. in diameter, cylindrical, slightly compressed, rarely branched or knotty; on the upper surface marked by circular, slightly alternate stem-scars. Externally brown, internally paler, speckled with numerous white dots; odor mousy and narcotic.

"*SCOPOLIA CARNIOLICA*, Jacquin, is obtained from Bavaria, Austro-Hungary, and southwestern Russia. The genus *Scopolia* is interesting, as it forms a connecting link between *hyoscyamus* and *atropa*. *Scopolia* is a rhizome and resembles the genus *atropa* in containing peculiar, crystal-like contents; but they are less prominent. Neither the bark nor the fibro-vascular bundles are so large or so numerous. The starch grains are likewise smaller. There

is a close alliance in the anatomy of these two plants, but all of the important characters are less pronounced than in belladonna. Belladonna scopolia is also a rhizome, and, like Japanese belladonna, may be distinguished from true belladonna, which is a root. Where a preparation claims to represent the Pharmacopoeia, which explicitly calls for the use of true belladonna, this drug should not be used. Messrs. W. H. Cole & Co., drug merchants, London, make the statement that "*Scopolia carniolica* is always picked and rejected as useless by makers of atropine."

ELECAMPANE (*Inula Helenium*, Linné) is the root of Inula. This root possesses resin cells, the taste is aromatic, and it is stained yellow by iodine—being free from starch.

MEDICAGO ROOT (*Medicago sativa*, Linné) has been noticed as an adulterant in Europe. It is distinguished from belladonna by a solid crown; the bark is thinner, and the medullium is tough and woody and traversed by numerous fine medullary rays.

MARSHMALLOW (*Althæa officinalis*, Linné) is said to be used as an adulterant for belladonna. It resembles the young uncut root. It is easily distinguished by its radiating wood, numerous bast fibres and mucilage. Holmes noted that belladonna root of the market had been found to contain as high as 50 per cent marshmallow root. It has been stated that some time ago the herbalists in Madrid offered for sale as belladonna a plant which was not belladonna, nor even belonging to the order Solanaceæ. It was called in the Madrid market "*Belladonna Silvestre de la casco de campo ares botanica cucubalus*" (*A. P. A.*, Vol. 21).

LAPPA (*Arctium Lappa*, Linné) root is sometimes admixed with belladonna. It is distinguished by its peculiar pith, its distinct radiating bark and being colored yellow by iodine and blue by ferric chloride" (Kilmer, in *Belladonna*). Mullein, foxglove and henbane leaves are said to be occasionally present as admixtures.

Scopolia carniolica (*Hyoscyamus Scopolia*, Linné) Jacquin and *Scopolia Japonica*, Maximowicz. The first of these plants has been shown to contain the principal constituents of belladonna, namely: Atropine, hyoscyamine, hyoscyne (scopolamine); furthermore choline and a fluorescent body, *scopoletin* (E. Schmidt), and has been used in this country for the production of atropine and in the preparation of belladonna plasters. The identity of *scopolamine* (scopoleine) ($C_{17}H_{21}NO_4$) and *hyoscyne* is above alluded to (see *Belladonna constituents*). Boiling with baryta water decomposes scopoleine into *atropic acid* ($C_9H_7O_2$) and crystalline *scopoline* ($C_8H_{13}NO_2$), which E. Schmidt believes to be identical with *methyl-scusulin*. The alkaloid scopoline may be synthetically combined with organic acids to form a series of compounds called *scopoleines*, of which scopolamine is a member (compare *Tropines* under *Atropina*). Scopoline is declared a more powerful mydriatic than atropine, causing dilatation sooner and lasting longer than that from the latter body. Internally, according to Sir Dyce Duckworth, it fails to affect the pupil and does not, like belladonna, produce dryness of the throat. Mr. Gordon Sharp (*Brit. Med. Journ.*) states that his personal experience leads him to believe that scopolamine, hyoscyne, daturine and duboisine differ but little in effects from atropine (E. M. J., 284, 1896). The drug needs further study.

II. *Other Mydriatic Plants and Alkaloids.* *Anisodus luridus*. Himalaya Mountains. A solanaceæ containing atropine and hyoscyamine (Siebert, 1890).

Atropa Mandragora, Linné (*Mandragora officinalis*, Miller; *Mandragora vernalis*, Brotero) and *Mandragora autumnalis* are Southern European stemless plants known as *Mandrake*, or *Mandragora*. Their roots, which are seldom seen in America, are sharp, bitter and narcotic. The root of *Atropa Mandragora* is spindle-shaped, and often divided below into two or three forks so as to somewhat resemble the human shape. On this account animal sensations were attributed to it by the ancients, who also fabulously declared that when torn from the earth it uttered shrieks like those of a human in distress. Dr. T. H. Silvester (1848), according to Lindley, was the first in recent years to call attention to the fact that it was formerly used like chloroform and other anesthetics now are, so that operations might be painlessly performed. Dioscorides describes the use of wine of mandragora before actual cautery and even amputation, and that a suppository of the juice and also emanations from the fruit were employed to induce sleep. A vulgar superstition attributed the power of promoting fecundity to amulets made of it. Botanically and therapeutically mandragora is related to belladonna. It contains two mydriatic alkaloids—one of which, called *mandragorine* ($C_{17}H_{23}NO_3$) is isomeric with atropine (Crouzel). This is without odor or color, and is deliquescent. Alkalies do not convert it into atropine. Mandragora and its alkaloids are not used in this country.

BENZENUM.—BENZENE.

FORMULA: C_6H_6 . **MOLECULAR WEIGHT:** 77.82.

SYNONYMS: *Benzol*, *Benzole*.

Source, History, and Preparation.—The name *Benzene* given to this substance should not be confused with that of the official *Benzin*, which is an entirely different substance and of an entirely different origin (see *Benzinum*). The name *benzol* would be preferable for benzene, but is rejected in chemical nomenclature on the ground that the ending "ol" indicates alcohols or phenols whereas benzene is a hydrocarbon. It is accepted in the parlance of chemical industry, however, to designate as *benzene* the chemically pure compound C_6H_6 , while the term *benzol* is reserved for the commercial product, which contains mainly benzene and varying quantities of toluene (C_7H_8), xylene (C_8H_{10}), and other homologues

(Sadtler, *Handbook of Industrial Organic Chemistry*). Benzene is one of the products of the destructive distillation of wood and coal. Its vapor occurs in the *illuminating gas* manufactured from coal, and in liquid form it is one of the constituents of wood- and coal-tar. It is obtained from coal-tar on a large scale by fractional distillation very much resembling the process by which the rectification of alcohol is effected (see *Alcohol*). Most of the benzene is contained in the portion distilling below 170°C . (338°F .), and is called *light oils* or *crude naphtha*; an aqueous layer of ammonia water likewise results, separating out from beneath the oils. By redistilling the light oils drawn off from the aqueous layer, three fractions are obtained—one below 110°C . (230°F .), another from 110° to 140°C . (230° to 284°F .), and a third from 140° to 170°C . (284° to 338°F .). The first fraction contains the bulk of benzol, the exact boiling point of which is 80.5°C . (176.9°F .). This fraction is purified by treatment with concentrated sulphuric acid, whereby olefines and empyreumatic resins are removed; the acid treatment is followed by caustic soda, then by water. The resulting oil is again rectified, and yields 90 per cent benzol, which is, by Allen's definition, a benzol, 90 per cent of which distills over before the temperature of 100°C . (212°F .) is reached (S. P. Sadtler). The residue is added to the second fraction, boiling between 110° and 140°C .; this, after treatment with sulphuric acid and with alkali as above, is again distilled, yielding 50 per cent benzol (the definition of which is analogous to that of 90 per cent benzol).

The fraction distilling between 140° and 170°C ., after chemical purification, is redistilled and yields *solvent naphtha*. A 90 per cent benzol of good quality consists, according to Allen, of "about 70 per cent benzene, 24 per cent toluene, including a little xylene, and 4 to 6 per cent of bisulphide of carbon and light hydrocarbons" (S. P. Sadtler, *Handbook of Industrial Organic Chemistry*).

Chemically pure benzene may be prepared by repeated fractional distillation of 90 per cent benzol, collecting only the fraction between 80° and 85°C . (176° and 185°F .), and finally subjecting the liquid to low temperature whereby benzol becomes solid and may conveniently be purified by pressure. An absolutely pure benzene is obtained by distilling benzoic acid with lime, the process being represented by the following equation: $\text{C}_6\text{H}_5\text{COOH} + \text{CaO} = \text{C}_6\text{H}_6 + \text{CaCO}_3$.

Description, Chemical Composition, and Test.—Benzene is a very mobile, inflammable, highly refractive liquid of an ethereal odor, boiling at 80.5°C . (176.9°F .), and having a specific gravity of 0.8991 at 0°C . (32°F .) and of 0.8841 at 15°C . (59°F .). It congeals at 0°C . (32°F .) and melts at 6°C . (42.8°F .). It is scarcely soluble in water, but easily soluble in alcohol and ether. It is an excellent solvent for resins and fats; also for phosphorus, iodine and sulphur. Commercial benzene contains *thiophen* ($\text{C}_4\text{H}_4\text{S}$) as a regular constituent, which was discovered, in 1883, by Victor Meyer. A mixture of nitric acid and sulphuric acid converts benzene into *nitrobenzene* (*nitrobenzol*), which has a bitter, almond-like odor. By this reaction benzene is easily distinguished from petroleum benzin (see *Benzinum*). Benzene (C_6H_6) has proved of the utmost theoretical and practical importance, it being the compound from which the vast class of *aromatic organic compounds* is derived.

Uses.—Benzene is employed in the arts on account of its power as a solvent for fats, resins, alkaloids, etc. Its most extensive application is in the manufacture of nitrobenzene, and of aniline and its derivatives; hence the importance of benzene in the industry of the coal-tar dyes (see *Anilinum*).

Related Products.—*Toluene* ($\text{C}_6\text{H}_5\text{CH}_3 = \text{C}_7\text{H}_8$). Molecular weight: 91.79. Toluene is the next higher homologue of benzene. Its boiling point is between 111° and 112°C . (231.8° and 233.8°F .), and is contained in the *light oils* resulting from the fractional distillation of coal-tar, from which source it may be isolated by proper rectification. It is also a constituent of *balsam of Tolu*, from which it may be obtained by dry distillation (see *Balsam of Tolu*).

BENZINUM (U. S. P.)—BENZIN.

SYNONYMS: *Æther petrolei*, *Petroleum benzin*, *Benzine*, *Petroleum ether*.

"A purified distillate from American petroleum, consisting of hydrocarbons, chiefly of the marsh-gas series (C_5H_{12} , C_6H_{14} , and homologous compounds). Benzin should be carefully kept in well-stoppered bottles or tin cans, in a cool place, remote from lights or fire" (U. S. P.).

Preparation and Purification.—Benzin is one of the products obtained when American crude petroleum, as it is found in Pennsylvania, West Virginia, Ohio, Kentucky, etc., is fractionally distilled for the purpose of purification. The first distillation yields 12 per cent of an impure fraction containing the benzin. This is again subjected to fractional distillation. As thus obtained the crude product has an objectionable odor which may be removed by shaking the benzin with sulphuric acid, or with lime. Grazer employs the mixed solutions of sulphuric acid and potassium bichromate. Beringer employs potassium permanganate, sulphuric acid, and soda (see *A. J. P.*, 1890, p. 6, for process).

Description.—This substance must not be confounded with *benzene* (*benzol*), which see. Benzin is thus described in the *U. S. P.*: "A transparent, colorless, diffusive liquid, of a strong, characteristic odor, slightly resembling that of petroleum, but much less disagreeable, and having a neutral reaction. Specific gravity: 0.670 to 0.675 at 15° C. (59° F.). Boiling point: 50° to 60° C. (122° to 140° F.). Insoluble in water; soluble in about 6 parts of alcohol, and readily soluble in ether, chloroform, benzol, and fixed and volatile oils. Benzin is highly inflammable, and its vapor, when mixed with air and ignited, explodes violently" (*U. S. P.*).

Chemical Composition and Tests.—Benzin consists chiefly of *pentane* (C_5H_{12}), *hexane* (C_6H_{14}), and *heptane* (C_7H_{16}), the former predominating in the benzin official in the *U. S. P.* "On evaporating benzin from the hand, it should leave no odor, and on evaporating it from a warmed dish, it should leave no residue (absence of heavy hydrocarbons). When it is boiled for a few minutes with one-fourth its volume of spirit of ammonia, and a few drops of silver nitrate T.S., the ammoniacal liquid should not turn brown (absence of pyrogenous products and sulphur compounds). If 5 drops of benzin be added to a mixture of 40 drops of sulphuric and 10 drops of nitric acid, in a test-tube, the liquid warmed for about ten minutes, and then set aside for half an hour, on diluting it, in a shallow dish, with water, it should not evolve the bitter-almond-like odor of nitro-benzol (difference from, and absence of, *benzol*)"—(*U. S. P.*). On account of its higher price benzene (frequently called benzol) is not likely to be an adulterant of benzin.

Pharmaceutical Uses.—Benzin is an excellent solvent for rubber, fats, some resins, and many of the alkaloidal bases. Fixed oils may be removed from powdered drugs by it, while volatile oils may also be prepared by percolating the drug containing them with this fluid. In some pharmacal operations it is employed in place of ether, but its solvent power on proximate plant constituents is so different as to render it unsafe in many cases where the product contains other bodies than oils, as, in the pharmaceutical oleoresins. It is largely used in the arts as a solvent, and on account of its resemblance in many respects to turpentine it is substituted for that solvent in painting and other operations.

Action, Medical Uses, and Dosage.—Vapors of benzin are reputed destructive to insect life, and in large doses its effects are said to resemble those of nitrobenzole. Mental confusion, dizziness, insensibility, convulsions, and intoxication as from alcohol, or coma are among its effects. By inhalation it has been used to mitigate the symptoms of *pertussis*; internally in *fermentative dyspepsia* and *trichinosis*. Locally it acts somewhat as an anæsthetic, giving relief to *neuralgic* and *rheumatic pain*. Boils are said to be aborted by its application, and it has been considerably employed in *parasitic skin diseases*. While it kills the itch-insect, it fails to destroy the eggs. Dose, 5 to 15 minims in capsule, in emulsion, or on sugar.

BENZONINUM (U. S. P.)—BENZON.

"A balsamic resin obtained from *Styrax Benzoin*, Dryander"—(*U. S. P.*).

Nat. Ord.—*Styracææ*.

COMMON NAMES: *Benzoin*, *Gum benzin*, *Gum Benjamin*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 169.

Botanical Source.—*Styrax Benzoin* is a tree from 50 to 70 feet high, with round, tomentose branches. The leaves are alternate, petiolate, oblong, entire, acuminate, smooth above, tomentose beneath, a palm long; the petioles are round, striated, tomentose, very short, and channeled. The flowers are on one side, in

compound, axillary racemes, nearly the length of the leaves; the common foot-stalks are tomentose; the partial alternate, spreading and tomentose. The calyx campanulate, very obscurely 5-toothed; outwardly tomentose; above a line in depth. The petals, numbering 5, are linear, obtuse, outwardly gray with very fine down, and four times longer than the calyx. Stamens 10; filaments inserted into the receptacle, rather shorter than the petals, beneath connate into a cylinder of the length of the calyx, and ciliated on the upper part below the anthers. The anthers are linear and longitudinally adnate to the petals. The ovary is superior, ovate and tomentose; the style filiform and longer than the stamens. The fruit is a globose drupe, containing 1 or 2 nuts, angular, concave on one side and convex on the other (L.).

History.—This beautiful tree presents a handsome appearance with its conspicuous crown of large spreading branches, bearing deep-green leaves, hoary white on the under surface. Its flowers are either white or reddish. The tree is indigenous to Sumatra (where it is cultivated), Java, and Borneo. A kind of gum is also produced in Siam and Cochin China, while along the east bank of the Mekong, it is said to be produced from the neighboring cassia forests. The botanical name of the tree, which is the source of the Siam gum, is unknown. The greater portion of the commercial benzoin is collected in the northern and eastern portions of Sumatra, and comes into English markets as *Gum Benjamin*, the tree from which it is derived being known as the Benjamin, or Benzoin, tree. This resinous balsam is obtained by making incisions into the bark of trees 6 or 7 years old, from which the balsam flows in the form of a thick, milky, resinous juice, which is allowed to remain until sufficiently hardened, when it is collected and new incisions made. The trees yield about 3 pounds of resin annually for a period of about a dozen years. The first 3 years' yield gives a superior product, containing a greater quantity of white tears, and is designated by the natives as *Head benzoin*. A browner resin, inferior to the above, which exudes during the remaining 7 or 8 years, is known as *Belly benzoin*. The least valuable product, *Foot benzoin*, is that obtained by cutting down the tree, splitting the wood and scraping it. In this way it becomes mixed with foreign matter, such as wood, bark, etc. Benzoin appears in commerce in the form of square masses, having been melted by sun heat or hot water and poured into square receptacles. While the resin is known to the Malays by the above names (which correspond to superior, medium, and inferior) it is known in commerce as two varieties—*Siam benzoin* and *Sumatra benzoin*.

Description.—Benzoin occurs in market in several grades, as regards the amount of milky-white tears contained in the mass. The Siam gum is regarded the most valuable, containing less foreign impurities than the Sumatra variety, the inferior grades of which are sometimes bark and but little resin.

SIAM BENZONIN comes in the form of square blocks having opaque, milky tears, often an inch or two in length, loosely adherent to each other. Usually, however, the tears are smaller, the mass more compact, the tears being imbedded in an amber-colored, or brown, resiniform material. Specimens containing the translucent resinous matter and very small tears, in appearance, are said to resemble Scotch granite. The tears show internally a semi-translucent, lamellated structure. Even the opaque tears become discolored and translucent by age. The resin is brittle, but may be readily softened by mastication, and has a pleasant fragrance, resembling that of the vanilla-bean. When heated benzoic acid is evolved.

SUMATRA BENZONIN also comes in rectangular blocks, usually having its tears imbedded in a grayish-brown resinous mass, intermixed with foreign matter. Its odor is not so pronounced nor as agreeable as that of the Siam product. A variety of Sumatra benzoin, of unknown origin, known as *Penang benzoin* (Benjamin), or *Storax smelling benzoin* (Benjamin) has a much more agreeable odor than the Siam variety, comparing somewhat with storax. It frequently consists of large tears, agglutinated together by a grayish resin. The fragrance of the different kinds of benzoin is best compared by adding water to their tinctures. The best variety (Siam) yields a reddish tincture, that of the other grades being yellow-brown or brown.

Benzoin is firm, brittle, pulverizable, of an agreeable, balsamic odor when rubbed, and of a sweetish, balsamic, somewhat acrid taste. When pure it is

wholly soluble in alcohol or ether. Upon exposure to heat, benzoïn consumes with the discharge of a dense, irritating, white smoke, consisting of benzoic acid and a fragrant empyreumatic oil. In pulverizing benzoïn, it irritates the lining membrane of the nostrils, causing sternutation. Water added to its alcoholic solution, precipitates it, forming a white liquid, which has been used as a cosmetic under the name of virgin's milk. Benzoïn has a specific gravity of about 1.068. Official benzoïn is thus described in the *U. S. P.*: "In lumps consisting of agglutinated, yellowish-brown tears, which are internally milk-white, or in the form of a reddish-brown mass, more or less mottled, from whitish tears imbedded in it. It is almost wholly soluble in 5 parts of moderately warm alcohol, and in solutions of fixed alkalies. When heated, it gives off fumes of benzoic acid. It has an agreeable, balsamic odor, and a slight, aromatic taste"—(*U. S. P.*).

That benzoïn does not lose its properties by keeping is evident from the fact that the best benzoïn we have ever seen was that recently recovered from a vessel wrecked in the East Indian trade two centuries ago.

Chemical Composition.—Benzoïn belongs to the class of substances known as balsam-resins. It contains a small amount of volatile oil, about 75 per cent of amorphous resins, and about 18 per cent of benzoic acid. The white tears contain the latter in smaller quantities than the resiniform substance in which they are imbedded. Among the empyreumatic products resulting from the dry distillation of benzoïn is a strongly fragrant, oily substance, designated *styröl*. *Cinnamic acid* ($C_9H_8O_2$) was found to be present in Siam and Penang benzoïn (Kolbe and Lautemann, 1860). Sometimes only this acid is present, to the exclusion of benzoic acid. Aschoff found cinnamic acid alone in a sample of the Sumatra product, while in the amygdaloid Penang and Siam varieties, only the benzoic acid was present (1861). Flückiger, however, obtained cinnamic acid from the latter variety. Rump believed that both acids were not simultaneously present in any variety of benzoïn, but that the cinnamic acid was present only in the Penang benzoïn. The resins of benzoïn, at least four in number, are all soluble in alcohol and caustic potash, but behave differently with other solvents, especially with ether. *Vanillin*, a product found mainly in vanilla, was obtained from Siam benzoïn by Rump, in 1878. Benzoïn was acted upon with caustic lime, the benzoic acid precipitated with chlorhydric acid, and the remaining liquid agitated with ether and evaporated, when a mixture of *vanillin* and benzoic acid remained.

Action, Medical Uses, and Dosage.—The effects of benzoïn are much the same as those of benzoic acid, which is its most abundant constituent, modified by the resin and essential oil. It is never given in bulk or alone. It is eliminated chiefly by the mucous membranes.

Benzoïn exerts a stimulating influence on the mucous tissues, and has been used to promote expectoration in chronic diseases of the air-passages. It is also stated to stimulate the sexual organs. It enters into the manufacture of elixir of paregoric, and constitutes the basis of Turlington's and many other balsams, which exert a salutary influence in healing wounds; the tincture is also employed to form a coating over the adhesive preparations so well known as *Court Plaster*. The fumes or vapor inhaled into the lungs, has been strongly recommended in *chronic pulmonary catarrhs*, and *old laryngeal inflammations*. The tincture is protective and stimulant in the early stage of *coryza* and as a dressing for *fresh wounds*. Benzoïn is principally used to prepare benzoic acid, to improve the taste and odor of other medicines, and in perfumery. The dose, in preparations, may be equivalent to 10 to 40 grains.

Related Products.—**PAGLIARI'S STYPTIC.** A preparation called *Pagliari's Hæmostatic or Styptic*, has been used with some degree of success in *hemorrhages*. It is made by boiling together for 6 hours in a glazed earthen vessel, alum 1 pound, tincture of benzoïn 8 ounces, water 10 pounds. As the water evaporates it must constantly be replaced with hot water, so as not to interrupt the ebullition, the resinous mass being stirred constantly. Then filter the fluid and keep in stoppered bottles. It is limpid, color of champagne, styptic in taste, and aromatic in odor. White resin has been successfully substituted for the benzoïn. Every drop of this fluid poured into a glass containing human blood produces an instantaneous magma; and by increasing the proportion of the styptic to the quantity of the blood, a dense homogeneous, blackish mass results. It is said to be useful in all *arterial* and *venous hemorrhages*. In applying it, lint and bandages should be used to prevent the coagula which form from being removed from the mouths of the vessels; an application of them for 24 or 48 hours is sufficient.

BERBERIS.—BARBERRY.

The bark of the root and the berries of *Berberis vulgaris*, Linné.

Nat. Ord.—Berberidaceæ.

COMMON NAME: *Barberry*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 16.

Botanical Source.—*Berberis vulgaris* is an erect, deciduous shrub, from 3 to 8 feet high, with long, bending branches which are dotted with triple spines. The leaves are obovate-oval, simple, closely serrulate, alternate, petioled, about 2 inches long, one-third as wide, and terminated by soft bristles. In their primary state they are 3-parted and spiny. The flowers, which are small and yellow, are borne in clusters on lax, pendulous racemes. The petals are entire; the stamens irritable, springing violently against the stigma when touched. The fruit consists of bright red, very acid, oblong berries, clustered in bunches (L.—W.).

History.—This shrub, a native of Europe, and naturalized in Asia, is found in the New England States, on the mountains of Pennsylvania and Virginia, among rocks, and in hard, gravelly soils; occasionally it is found in the West on rich grounds. It flowers from April to June, and ripens its fruit in June. "It is frequently planted in gardens and prized for the beautiful bunches of red berries which hang after the leaves have fallen. The plant is generally a shrub from 2 to 8 feet high, although Loudon is authority that 'there are examples of trees 30 feet in height' and that 'they live for two or three centuries.' The wood contains a yellow, bitter coloring matter, and is sometimes used as a dye. The flowers are in pendulous racemes and appear in May or June. The leaves are obovate, bristly serrate, tapering at the base to a very short petiole. They are agreeably acid, resembling in this respect the leaves of the *Nat. Ord.*—Oxalidaceæ. The French name for barberry, *Epine vinette*, means literally an acid thorn. The fruit is a bright scarlet, berry, and has an intensely, yet agreeably acid taste. It is said to make excellent preserves; was highly esteemed by the ancients, and probably would be now, if other fruits had not been cultivated to such a degree of excellence. The name *berberis* seems to have been first applied to this fruit by Averroes, an Arabic writer on medicine, who wrote in the Twelfth century" (*Berberidaceæ*, by C. G. and J. U. Lloyd, p. 5). Barberry bark, it is stated, has been used as an adulterant of pomegranate root bark.

Description.—This drug is the foliaceous bark of the barberry root, and occurs in thin sections, having an orange-yellow, smooth inner surface; externally it has a soft, yellow-gray periderm. It breaks with an abrupt fracture, exhibiting a vivid yellow interior. Its laminated structure permits of its being separated into layers. It has a bitter, non-astringent taste, but no odor. When chewed it imparts a yellow color to the saliva. In Europe the whole root is frequently employed. It is thick and tough, very much branched and hard. Externally it has a brown color; internally it is yellow, the color extending throughout the light, thick wood. Like its bark it is bitter and without odor.

Chemical Composition.—*Berberine* (see *Hydrastis*) is the active alkaloidal principle of this drug. It has also been found in *Hydrastis*, *Podophyllum*, and other plants. According to Brande, the bark likewise contains gum, starch, fatty matter, chlorophyll, bitter yellow extractive (probably the above alkaloid in an impure condition), brown coloring matter, a resinous substance, lignin and water. Other alkaloids have also been found in this bark, viz.: *Oxyacanthine* ($C_{17}H_{21}NO_3$), also called *berbine* and *vinetine*; and *berbamine* ($C_{15}H_{19}NO_3$) (see *Berberis aquifolium*). A fourth alkaloid, in an amorphous condition, has also been obtained from it. A very little tannin is also said to be present, sufficient to give a green color with the ferric salts. The flowers contain sugar and an essential oil, while malic acid is present in the berries.

Fig. 46.

Berberis vulgaris.

Action, Medical Uses, and Dosage.—"Berberis vulgaris, a native of Europe, is now quite common in this country, and for many years has been in domestic use as a medicine. A tea made from the bark is taken during the spring months as a blood purifier. A strong decoction is employed as an application to the sores which sometimes afflict children's lips, and in certain conditions of the system demanding tonic treatment, the infusion is a favorite remedy. The fluid extract is usually administered. It is readily prepared by those having the proper facilities, and can easily be made to represent the bark, fluid ounce to troy ounce. It is more satisfactory in its action than the alkaloid berberine" (Lloyd's *Berberidaceæ*). Berberis is a tonic and laxative. Formerly used extensively by practitioners in the New England States, in all cases where tonics are indicated, also in jaundice, and chronic diarrhoea and dysentery. The berries form an agreeable acidulous draught, useful as a refrigerant in fevers, also beneficial in dysentery, cholera infantum, diarrhoea, etc. The bark is bitter and astringent, and has been used with advantage as a tonic. The bark of the root is the most active; a teaspoonful of the powder will act as a purgative. A decoction of the bark or berries, has been found of service as a wash in aphthous sore mouth, and in chronic ophthalmia.

Webster declares it of value in jaundice when there is no obstruction of the bile ducts, and in doses short of purgative stimulates the duodenal functions, relieving intestinal dyspepsia. Small doses are also palliative in renal calculi, and in soreness, burning, and other unpleasant sensations of the urinary tract.

Related Species.—"Berberis Canadensis is our only indigenous species of the Berberis proper. It very closely resembles the berberis vulgaris, but is a smaller shrub, with smaller leaves, smaller berries, and smaller and fewer flower racemes. Its locality is farther South than the introduced species, being a native of the Southern States. The acidity of the fruit and leaves and the yellow color of the wood are also observed in this species. It closely resembles the foregoing in medicinal properties. Doubtless it contains much the same principles, as the two species closely resemble each other and are used commonly for the same purpose" (*Berberidaceæ*, C. G. and J. U. Lloyd; see also *Berberis aquifolium*).

BERBERIS AQUIFOLIUM.—OREGON GRAPE.

The root of *Berberis aquifolium*, Pursh (*Mahonia aquifolium*, Paxton).

Nat. Ord.—Berberidaceæ.

COMMON NAMES: Mountain grape, Oregon grape.

ILLUSTRATIONS: Pursh, Vol. I, Plate iv; *Botanical Register*, 1425.

Botanical Source.—*Berberis aquifolium* is a shrub having stems about 6 feet high, erect, and of rapid growth. The leaves are alternate, and consist of

Fig. 47.

Leaves of *Berberis aquifolium*.

3 or 4 pairs of leaflets, and an odd one. They are evergreen, coriaceous, bright and shining upon the upper surface, and very ornamental; hence, the shrub is frequent in cultivation, often under the improper name "holly." The leaflets are smooth, ovate, from 2 to 3 inches long, and one-half as wide. They are acute, sessile, pinnately veined, and the margin is indented with from 15 to 30 repand spiny teeth. The lower pair of leaflets is from 1 to 2 inches distant from the base of the common petiole. The flowers are numerous, small, yellowish-green, and appear in early spring, borne in fascicled, terminal racemes. The calyx has 9 distinct sepals, colored like the petals and disposed in 2 rows, the outer of which consists of 3 sepals (bracts?). The petals are 6, distinct, orbicular, and in rows of 3 each. The stamens are also 6, and opposite the petals; they have irritable filaments, and extrorse anthers, opening, each by 2 little valves, hinged at the top. The fruit, which is known as "Oregon grape," is a cluster of purple berries, each containing an agreeably acid pulp, and from 3 to 9 seeds.

History.—This is a tall shrub, native of the western section of the United States. It grows from Colorado to the Pacific Ocean, and is especially abundant in Oregon and the northern part of California. *Berberis aquifolium* belongs to the section *Mahonia* of the genus *Berberis*, which section is considered by some botanists a distinct genus. The following synopsis of the difference between the two sub-genera is taken from "*Berberidaceæ*" (a pamphlet by C. G. and J. U. Lloyd, 1878):

"The *Berberis* proper has simple leaves clustering in the axis of a simple or 3-parted spine. The petals have two glands on the inside of each, at the base. The filaments have no teeth. Berries 2 to 3-seeded.

"*Mahonia* has oddly, pinnately, compound leaves, with no spine at the base, but with spiny-toothed leaflets. The petals are glandless. The stamens have a tooth on each side of the filament, near the top. Berries 3 to 9-seeded."

The section "*Mahonia*" is represented in the western United States by six species, viz.: *Berberis pinnata*, Lag., a tall shrub with the general appearance of *B. aquifolium*, distinguished from it by the leaflets, which are glaucous underneath, and the lower pair approximate to the base of the petiole; *Berberis repens*, Lind., a small creeping plant, with leaves often ternate, and leaflets nearly orbicular, and which has been much confounded, and frequently described as *Berberis aquifolium*. *Berberis nervosa*, Pursh, a small erect shrub, with leaves often longer than the stem—it appears to be more generally distributed than the other species. The chief characteristics of this species are, the leaflets are three-veined from an oblique base, the common petiole is jointed "like a bamboo stem," and the flowers are in slender racemes. The two other species, *B. Fendleri* and *B. Fremonti*, are of rare occurrence.

Berberis aquifolium and the other species long in use in domestic practice throughout the West, were brought into general notice a few years since by Parke, Davis & Co., of Detroit, who gave the remedy great conspicuity. Dr. Bundy, of Colusa, Cal., wrote many papers on its therapy; these were published in their journal, "*New Preparations*." From an examination of the drug, as thrown upon the market, we find the species are confounded, several of them being generally sold as *B. aquifolium*. The *B. nervosa* is more commonly met with in these sophistications, but we have likewise noticed *B. repens* in considerable amount. The confusion is, perhaps, unimportant from a therapeutical point, as all the *Mahonias* are bitter, and seem to contain *berberine* in nearly the same proportion (see *Related Species*).

Description.—The root of *Berberis aquifolium* is from $\frac{1}{2}$ to 1 inch in diameter, often increasing to 2 and 3 inches at the base of the stem. It is woody, yellow throughout, and very hard. The bark is deep-yellow beneath and brown upon the surface. It is without odor and very bitter. The roots of the other species of *Mahonia* are smaller; the *B. pinnata* more nearly approaching the *B. aquifolium* in size; the *B. repens* is the smallest of any of the known species.

Chemical Composition.—*Berberis aquifolium* contains *berberine*, a yellow alkaloid (see *Hydrastis*), *berbamine*, and *oxyacanthine*, both white alkaloids, and *phytosterin*, gum and sugar. The flowers contain, in addition to the above alkaloids, volatile oil, and the berries contain malic acid.

The presence of *berberine* renders both root and bark bitter. The white alkaloid, *oxyacanthine* ($C_{15}H_{21}NO_3$, Rüdel), which forms soluble salts with most acids, is itself practically insoluble in water, soluble in hot alcohol and hot ether, and slightly so in cold alcohol and cold ether. It dissolves freely in fats and volatile oils, and in chloroform and benzol. It is alkaline, bitter, and in the presence of sunlight changes color, becoming yellowish. Iodic acid is reduced by it with the liberation of free iodine. With nitric acid a yellow color is produced, which, when heated, changes to purple. Cold sulphuric acid turns it brownish-red; on heating it changes to a vivid red, and finally a brown color. With ferric chloride, in dilute solution of potassium ferricyanide, a blue color is produced with salts of *oxyacanthine*. Other names have been given this alkaloid to avoid confounding it with products of a species of thorn-apple, the *Crataegus Oxyacantha*. Thus *vine-tine* was applied to it by Wacker, while Berzelius christened it *berbine*. *Berbamine* ($C_{15}H_{21}NO_3$) is a white alkaloid the salts of which dissolve slightly in solutions of

Chili saltpetre (nitrate of sodium). These salts strike a blue color with ferric chloride in a weak solution of ferricyanide of potassium. *Phytosterin* ($C_{27}H_{48}O.H_2O$) is a neutral body (found also in Calabar bean, *Physostigma venenosum*, Balfour), differing from *cholesterin*, which it closely resembles, by its solution in chloroform not having any affect on polarized light.

Action, Medical Uses, and Dosage.—This agent has justly been extolled as an alterative and tonic, and has been recommended in *syphilitic affections*, *salt-rheum*, *pityriasis*, *psoriasis*, and other *cutaneous affections*, as well as in maladies supposed to be due to some mal-condition of the blood. Excretion and secretion are promoted by it; digestion and assimilation improved; the lymphatic glandular system and the ductless glands are stimulated; and the renal secretions somewhat augmented. Thus it acts as a blood-maker, and is therefore a remedy to oppose depraved conditions of the body-fluids. As a tonic, it may be employed as a synonym of *hydrastis*, *colombo*, *berberis*, etc., possessing in addition its own peculiar virtues, in *dyspeptic conditions*, *chronic mucous maladies*, and in certain enfeebled conditions of the system, etc. Owing to its invigorating power over the gastric functions, it is a valuable remedy for *atonic dyspepsia*, and more particularly if associated with hepatic torpor, for which it is also an excellent remedy. A *cirrhotic liver*, associated with gastro-enteritis, has been benefited by it, and for *chronic constipation* it is a useful agent when combined with *cascara sagrada*. It is said to be effectual in *stomatitis*.

The great field for *berberis aquifolium* is in *constitutional syphilis* and its manifold complications and sequelæ. The disorders named above are more amenable to this drug when associated with a syphilitic taint than otherwise. If given early enough it will prevent tertiary phases, provided the patient has not been too thoroughly mercurialized. Its use must be prolonged in appreciable doses. It is especially adapted to long-standing cases of syphilis, the older the better, according to some of its advocates, and yet it is a remedy of much value all through the course of the disease. It is the remedy for that broken-down state so frequently following in the wake of that malady. The various eruptions give way to it, the gastric complications are subdued, and the mucous membranes are toned so that excessive secretions are restrained. The bone and periosteal, as well as the muscular, pains of syphilitics, are amenable to *berberis*. Its action is slow but sure, as it is also in severe muscular pains, with partial paralysis, due to spinal disease. Long standing *syphilitic phagadenæ* and *herpetic* and *eczematous states*, yield to it better than to most agents. It should not be forgotten in *syphilitic anemia*. Several stubborn cases of *psoriasis* (Ed. E. M. J., p. 148, 1896) have been cured by it, and it is a valuable drug in *erysipelatosus* and *chronic scrofulous affections*. While it has failed to cure *carcinoma*, as its introducer, Dr. J. H. Bundy, believed it would, it has, however, shown itself of value in the dyscrasiæ due to a *cancerous cachexia*.

Berberis aquifolium commends itself for study in certain pulmonic troubles, on account of its excellent results in controlling secretions of the mucous tract. Cases of *purulent bronchorrhœa*, pronounced incurable, have been cured by it, and Prof. Webster asserts that he has seen cases of *phthisis* recover, even where there were extensive cavities, under the use of this agent. The appetite improved, hectic subsided, expectoration became lessened, the cough milder and less frequent, and flesh and strength were augmented. The remedy should be long continued. *Berberis* is of some value in *leucorrhœa*, and particularly when a syphilitic taint exists. Owing to its remarkable power over mucous structures we would suggest its employment in *gastric* and *intestinal catarrh*. The principal uses of this drug have been developed by Dr. J. H. Bundy and Prof. Herbert T. Webster. The dose of *berberis aquifolium* should be relatively large. Small doses, as required of most of our important agents, do but little good.

The dose of the fluid extract is from 10 to 20 drops every 3 or 4 hours; of specific *berberis aquifolium* 5, 10 or 15 drops, every 3 or 4 hours.

Specific Indications and Uses.—Syphilitic dyscrasiæ, constitutional syphilis, with periosteal or muscular pains; chronic skin affections, with blood dyscrasiæ; profusely secreting, tumid mucous tissues; indigestion, with hepatic torpor; yellow skin, with marked weakness and emaciation.

Related Species.—*MAHONIA*, the sub-genus of the genus *berberis*, is a fine, showy family of evergreen shrubs. The distinction between this sub-genus and the *berberis* proper,

although very obvious, is not considered sufficient by authorities to entitle it to the rank of a distinct genus, hence the generic name is berberis, the same as the common barberry. The two species of the berberis proper, which grow in this country, are both deciduous shrubs, although there are several evergreen species found in the Old World. All the plants of the sub-genus, mahonia, are evergreen, and on this account they are often cultivated in yards and cemeteries, frequently under the improper name holly. There are four indigenous species found in the United States, all west of the Mississippi, and there are also a few other species in Mexico. Our native species are *B. nervosa*, *B. repens*, *B. pinnata*, and *B. aquifolium*. The two former are small plants, never over 2 feet high, and often only a few inches, while the other two are large shrubs from 3 to 6 feet high; hence by their height alone *B. nervosa* and *B. repens* can be distinguished from *B. pinnata* and *B. aquifolium*.

"*B. nervosa*, Pursh, is a little erect shrub, with leaves often longer than the stem. The leaves consist of 3 to 6 pairs of leaflets and an odd one. The main leaf stalk of each leaf is very conspicuously jointed at each pair of leaflets, as remarked by Dr. Lindley, 'like a bamboo stem.' The leaflets are ovate, lanceolate, acute or acuminate; triple veined from the oblique base, and have teeth, not repand, but serrate. The flowers are in erect racemes, which are more slender than those of any other species. The plate of *B. nervosa*, tab. 5, vol. 1, in Pursh's work, is spurious. The leaves are correct, as intended, but the flowers are of the *B. aquifolium*. Since the plate is made up of two species, and hence liable to confuse, Lindley proposed to remedy the matter by changing the name to *B. glumacea*, but the change was not received with favor by botanists, and the name *B. nervosa* is still applied to the plant.

"*B. repens*, Lindley.—A small shrub, procumbent, with short, erect branches. The leaves are often ternate, but generally of 5 or 7 leaflets. Leaflets are ovate, orbicular, acute, or the terminal leaflet obtuse; pinnately veined with repand teeth. Flowers in terminal fascicled racemes.

"*B. repens* and *B. nervosa* are both employed by the western miners as blood purifiers, and as an antiperiodic, the *B. repens* extensively. We have several letters from physicians in widely separated portions of the great West, enclosing leaves of these varieties for us to classify and examine, all saying the root is extensively used for the above purpose. It is made into infusions and decoctions. The acid berry of the *Berberis repens*, under the name 'mountain grape,' is made into confections and freely eaten. It acts as an antiscorbutic, and is of great benefit to persons long deprived of fruit.

"The following description was kindly furnished by Dr. C. L. Aylworth, of Montana State: 'The plant I enclose for description is called the Oregon grape. The fruit is eaten. It grows in medium or rich soil, among rocks or bushes, seldom in open ground. It is more plentiful upon the foot-hills of mountains, and along the banks of mountain streams, extending far down into the valleys. It does not grow in clusters, but I have seen it nearly cover the ground. It is common about all the small streams in this section of the Yellowstone valley, and about the headwaters of the Missouri river.'

"The root of the *B. repens* is a small, vine-like rhizome, resembling somewhat in appearance the *Menispermum C.*, though not so fibrous. It is yellow throughout, woody, hard, and brittle. The bark, yellow within, is brown upon the surface and easily separated. The root and bark contain a large amount of berberine, which, together with other principles, is readily extracted by alcohol. It contains a principle in combination, precipitated by alkalies from aqueous solution. This, very likely, is identical with the white alkaloid of *Hydrastis canadensis*, or oxyacanthine.

"The medical profession at large is not acquainted with either of these plants under their proper names, although they may be upon the market for *B. aquifolium*.

"*B. pinnata*, Lagasca.—This is the only species that is liable to be confused with the medicinal species, *B. aquifolium*, as both are about the same size, and closely resemble each other. The leaflets are lanceolate, acuminate, and of a light-green color, glaucous on the under side. There are 2 to 6, seldom more, large teeth on each side of the leaflet, each ending in a slender spine. The specific character by which this species may always be distinguished from the *B. aquifolium*, is the position of the lower pair of leaflets. These leaflets are approximate to the base of the common petiole in the *B. pinnata*, and never at a distance from it, as they are in the *aquifolium*.

"*B. pinnata*, often called *Mahonia pinnata*, has not been used by the medical profession unless in local practice. It has been mistaken for *B. aquifolium*, which it nearly resembles, and from which its root can not be easily distinguished. Its berries are eaten by western settlers, and a tea from the root is used as a medicine" (from *Berberidaceæ*, by C. G. and J. U. Lloyd) (see also *Berberis* and *Berberis aquifolium*).

BETULA LENTA.—BLACK BIRCH.

The bark and leaves of the *Betula lenta*, Linné.

Nat. Ord.—Betulacæ.

COMMON NAMES: Cherry birch, Black birch, Sweet birch, Mahogany birch, Mountain mahogany.

Botanical Source.—Black birch is a large tree growing from 50 to 70 feet in height, with a diameter of from 2 to 3 feet. Its leaves are cordate-ovate, acuminate,

acutely and finely doubly serrate, hairy on the veins beneath, and on the petioles. The fertile aments are erect, elliptical, thick, and somewhat hairy; the sterile aments are from 2 to 3 inches long, longer than the fertile, and not so thick; the lobes of the veiny scales are nearly equal, obtuse, and diverging (W.—G.).

History.—This is a well known tree, growing in various parts of the United States. The trunk is invested with a dark-brown or reddish bark, which becomes rough in old trees, and has, together with the leaves, an aromatic flavor and taste, somewhat similar to wintergreen (*Gaultheria procumbens*, Linné); the wood is of a reddish color, strong, compact, and takes a fine polish; it is much used in cabinet work. The cambium is used in the spring by boys as a delicious morsel. The bark is the part used, and yields its properties to water. The leaves also possess active properties.

Chemical Composition.—The bark of this tree contains tannin. Both the bark and leaves yield a volatile oil, to which is due their peculiar and pleasant aroma. This oil is largely sold as oil of wintergreen, either wholly substituted for the latter, or mixed with it. Its identity with oil of gaultheria was pointed out by Prof. Procter, in 1843, who also called attention to the fact that it was a product—that it did not exist pre-formed in the bark as found on the market, but that it was the result of the mutual reaction between a neutral compound of the bark (somewhat similar to *amygdalin*) to which he applied the name *gaultherin*, and water. This oil was shown by Pettrigrew (1883) to be a very pure methyl salicylate (see *Oleum Gaultheriæ*).

Action, Medical Uses, and Dosage.—Gently stimulant, diaphoretic, and astringent. Used in warm infusion whenever a stimulating diaphoretic is required; also in *diarrhœa*, *dysentery*, *cholera infantum*, etc. In decoction or syrup it forms an excellent tonic to restore the tone of the bowels, after an attack of *dysentery*. Said to have been used in *gravel* and *female obstructions*. Oil of birch will produce a drunken stupor, vomiting, and death. It has been used in *gonorrhœa*, *rheumatism*, and *chronic skin diseases*. Dose, 5 to 10 drops.

Related Species.—*Betula alba*, Linné. *European birch*, *White birch*. Europe, America north of Pennsylvania, and North Asia. This tree yields a brown, warty bark from the limbs, and a whitish bark from the body of the tree, separating in paper-like layers. The bark has a bitter, astringent taste. Chemical manipulations of the latter have brought forth a camphoraceous substance known as *betulin* (*betula camphor*), having the composition $C_{26}H_{40}O_3$. It forms light crystalline flocculi, which when heated to $258^{\circ}C.$ ($496^{\circ}F.$), fuse as a tasteless mass, capable of being sublimed if carefully heated. It dissolves in hot alcohol, ether, alkaline solutions, and essential oils. By oxidation it splits up into two acids, *betulinic* ($C_{26}H_{40}O_{10}$) and *betulinamaric* ($C_{26}H_{40}O_{12}$) acids. A balsamic essential oil is obtained by distilling the young shoots and twigs, while the bark and wood, by destructive distillation, yield a tar-like body known as *dagget* or *birch-tar*. This, when distilled, yields *oleum rusci* (*ol. betulinum*; *ol. muscorum*). This is an empyreumatic, brownish-red oil. This oil, birch-tar, and *betula camphor* (during dry distillation) give off an odor which resembles that of Russian leather, in the preparation of which the empyreumatic oil of birch is said to be largely employed. *Betulo-resinic acid* ($C_{26}H_{40}O_8$), is a powdery substance found on the leaves and young twigs of the tree. The white birch is a favorite remedy in northern Europe, where it is abundant. A spiritous beverage is prepared from the sap (through the intervention of yeast) by the peasants, and the sap itself is esteemed valuable in *cutaneous disorders*, *renal* and *genito-urinary affections*, *scurvy*, *gout*, *rheumatism*, and *intermittent febrile states*. An infusion of the leaves has been employed in *rheumatism*, *skin diseases*, *gout*, and *dropsy*, while for the rheumatic a bed of fresh leaves is prepared, and is said to occasion profuse diaphoresis. A pulpy mass of the bark, with gunpowder, is employed for *scabies*. The oil has been used internally in *gonorrhœa*, and externally in *skin eruptions*, especially those of an eczematous type.

Betula papyracea, Aiton. *Canoe birch*. Northern United States. The strong white bark of this species, which forms papyraceous layers, is used by the American Indians in covering their canoes.

BIDENS.—SPANISH NEEDLES.

The root and seeds of *Bidens bipinnata*, Linné.

Nat. Ord.—Compositæ.

COMMON NAME: *Spanish needles*.

Botanical Source and History.—*Bidens bipinnata* is an annual plant, with a smooth, branched stem growing from 1 to 4 feet high. The leaves are bipinnately parted, nearly smooth and petioled; the leaflets ovate-lanceolate, pinatifid, mostly wedge-shaped at the base; the heads of flowers on slender

peduncles, each with 3 or 4 obscure, obovate, yellow rays; the outer involucre of linear scales are as long as the inner, and nearly as long as the short, pale, yellow rays; the achenia are long and slender, 4-grooved and angled, nearly smooth, 3 or 4-awned, and adhere to the dress and to the fleece of animals (G.—W.).

This is a common plant, growing in waste places on dry soils, flowering from July to September, and found from Connecticut to Pennsylvania and westward. The root and seeds of this and the related plants below mentioned are employed medicinally, and may be used in decoction, infusion, or tincture.

Action, Medical Uses, and Dosage.—Emmenagogue and expectorant; the seeds in powder or tincture have been successfully used in *amenorrhœa*, *dysmenorrhœa*, and some other *uterine derangements*; and an infusion of the root has proved beneficial in severe *cough*. *Hay asthma* has recently been treated with it. Infusion freely administered.

Related Species.—*Bidens frondosa*, Linné. *Common beggar-ticks*. Europe and United States. This plant has a smooth, branching, rather hairy stem, from 2 to 6 feet high. Leaves 3 to 5, divided; leaflets lanceolate, pointed, coarsely-toothed, mostly stalked; outer leafy involucre much longer than the head, ciliate below; rays none; flowers in clusters at the end of the branches, yellow; achenia wedge-obovate, 2-awned, the margins ciliate with upward bristles, except near the summit. This is a common, very troublesome weed, growing in moist, cultivated fields throughout the United States; the achenia, as in the other species, adhering by their retrorsely-barbed awns to clothes, etc. It flowers from July to September (G.—W.). *Bidens frondosa* in infusion has cured several cases of *croup*, even where they have been considered beyond aid. A strong infusion of the plant, sweetened with honey, was administered to the children, warm, in doses of a tablespoonful or more every 10 or 15 minutes, until it vomited. A quantity of mucous and membranous shreds were ejected, followed by immediate relief; the children passed into a sleep, from which they awakened perfectly well. In a few hours after the emetic operation of the warm infusion, it acted as a cathartic. The leaves from which the infusion was made, were, at the same time placed in a piece of flannel with some brandy added to them, and laid over the chest and throat. This plan is also beneficial in *colds*, *acute bronchial* and *laryngeal attacks* from exposure to cold, etc. An infusion of the seeds formed into a syrup with honey, is useful in *whooping-cough*. Dr. Scudder directs attention to its action on the heart and circulation, suggesting investigations in this line.

Fig. 48.

Bidens frondosa.

Bidens connata, Willdenow (*Bidens tripartita*, Linné). *Cuckold's*, or *Swamp beggar-ticks*, has a smooth stem, 4-furrowed, with opposite branches, and grows from 1 to 3 feet high; the leaves are lanceolate, opposite, serrate, acuminate, slightly connate at the base; the lower ones are mostly trifid; the lateral divisions are united at the base, decurrent on the petiole; the scales of the outer involucre are longer than the head, leafy, mostly obtuse, scarcely ciliate; rays none; the achenia is narrowly wedge-form, 2, 3, or 4-awned, with downwardly-barbed margins; the flowers are terminal, solitary, consisting only of the tubular, yellow florets, surrounded by a leafy involucre. This is likewise a common weed found in wet grounds, rich fields, swamps, and ditches, from New England to Missouri. It flowers in August (G.—W.). *Bidens connata* has likewise been recommended in the above affections, also in *palpitation of the heart*, in which the infusion or decoction, drank freely through the day, has been found effectual.

Bidens cernua, Linné, *Bur-marigold*. Europe, Canada, and the United States. The leaves are subconnate, dentate, and lanceolate; the external scales are long as disk; the rays are pale yellow, few or none; the heads are *cernuous* (nodding). Swamps and ditches. For the uses of all three species, see also *Bidens bipinnata*.

BISMUTHI CITRAS (U. S. P.)—BISMUTH CITRATE.

FORMULA: $\text{BiC}_4\text{H}_5\text{O}_7$. MOLECULAR WEIGHT: 397.44.

SYNONYMS: *Bismuthum citricum*, *Citras bismuthicus*, *Citrate of bismuth*.

Preparation.—"Bismuth subnitrate, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; citric acid, seventy grammes (70 Gm.) [2 ozs. av., 205 grs.]; distilled water, a sufficient quantity. Boil the bismuth subnitrate and the citric acid with four hundred cubic centimeters (400 Cc.) [13 fl. oz., 253 M.] of distilled water for about 15 minutes, or until a drop of the mixture yields a clear solution with ammonia water. Then add five thousand cubic centimeters (5000 Cc.) [a little more than 5½ quarts] of distilled water, allow the suspended matter to deposit, wash

the precipitate, first by decantation, and afterward on a strainer, with distilled water, until the washings are tasteless, and dry the residue at a gentle heat' (U. S. P.).

In this process decomposition ensues with the formation of anhydrous bismuth citrate, nitric acid, and water, the salt thus formed being almost insoluble in the two latter bodies. The reaction takes place according to the equation: $\text{BiNO}_3(\text{OH})_2 + \text{C}_6\text{H}_8\text{O}_7 = \text{BiC}_6\text{H}_5\text{O}_7 + \text{NO}_3\text{H} + 2\text{H}_2\text{O}$, and is complete when ammonia water ceases to cause a precipitate of $\text{BiO}(\text{OH})$ in the supernatant liquid.

Description and Tests.—"A white, amorphous or micro-crystalline powder, odorless and tasteless, and permanent in the air. Insoluble in water or alcohol, but soluble in ammonia water, and in solutions of the citrates of the alkalis. When strongly heated, the salt chars, and, on ignition, leaves a more or less blackened residue having a yellow surface, and soluble in warm nitric acid. This solution, when dropped into water, occasions a white turbidity. A solution of the salt in ammonia water, when treated with hydrogen sulphide in excess, yields a black precipitate. If the filtrate from the latter be deprived by heat of the excess of hydrogen sulphide and cooled, a portion of it, boiled with lime-water, yields a white precipitate. If another portion of the cooled filtrate be mixed with an equal volume of concentrated sulphuric acid, and again cooled, no brown or brownish-black color should appear around a crystal of ferrous sulphate dropped into the liquid (limit of nitrate)"—(U. S. P.).

Pharmaceutical Uses.—Used chiefly in preparing *Bismuthi et Ammonii Citras*.

BISMUTHI ET AMMONII CITRAS (U. S. P.)—BISMUTH AND AMMONIUM CITRATE.

SYNONYMS: *Bismuthum citricum ammoniatum*, *Bismuthi ammonio-citras*.

Preparation.—"Bismuth citrate, one hundred grammes (100 Gm.) [3 oss. av., 231 grs.]; ammonia water, distilled water, each, a sufficient quantity. Mix the bismuth citrate with two hundred cubic centimeters (200 Cc.) [6 fl. 3, 367 M.] of distilled water to a smooth paste, heat the mixture on a water-bath, and gradually add ammonia water, until the salt is dissolved, and the liquid is neutral or has only a faintly alkaline reaction. Then filter the solution, evaporate it on a water-bath to a syrupy consistence, and spread it upon plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in small, well-stoppered bottles, protected from light."

Description and Tests.—A somewhat variable salt, from the fact that no provision is made in the preceding process for the loss of ammonia, which necessarily occurs during the process of concentration. It is employed in the preparation of *Liquor Bismuth* (see *Liquor Bismuthi et Ammonii Citratis*), the original preparation of which was long kept secret by Mr. Schacht, of England. This salt, when dry, through loss of ammonia, becomes partially insoluble in water. If, however, a little ammonia water be cautiously added to the imperfect solution a clear liquid will result. The official description of this salt, and the tests for its purity are as follows:

"Small, shining, pearly or translucent scales, odorless, having a slightly acidulous and metallic taste, and becoming opaque on exposure to the air. Very soluble in water, and but sparingly soluble in alcohol. When strongly heated, the salt fuses, and finally leaves a more or less blackened residue, having a yellow surface, and soluble in warm nitric acid. This solution, when dropped into water, occasions a white turbidity. The aqueous solution of the salt is neutral or faintly alkaline to litmus paper. When boiled with potassium or sodium hydrate T.S., it evolves the vapor of ammonia, and when treated with hydrogen sulphide, it yields a black precipitate. If the filtrate from the latter be deprived by heat of the excess of hydrogen sulphide and cooled, a portion of it, boiled with lime water, yields a white precipitate. If another portion of the cooled filtrate be mixed with an equal volume of concentrated sulphuric acid, and again cooled, no brown or brownish-black color should appear around a crystal of ferrous sulphate dropped into the liquid (absence of nitrate)"—(U. S. P.).

Medical Uses.—(See *Liquor Bismuthi et Ammonii Citratis*).

BISMUTHI OXIDUM.—BISMUTH OXIDE.**FORMULA:** Bi_2O_3 . **MOLECULAR WEIGHT:** 465.68.**SYNONYMS:** *Bismuthum oxydatum*, *Oxydum bismuthicum*.

Preparation.—“Take of subnitrate of bismuth 1 pound (av.), solution of soda 4 pints (Imp.). Mix and boil for five minutes; then, having allowed the mixture to cool and the oxide to subside, decant the supernatant liquid, wash the precipitate thoroughly with distilled water, and finally dry the oxide by the heat of a water-bath” (*Br. Ph.*).

In this process bismuth hydroxide is formed, which precipitates, leaving sodium nitrate in solution thus, $2(\text{BiONO}_3 \cdot \text{H}_2\text{O}) + 2\text{NaOH} = 2\text{Bi}(\text{OH})_3 + 2\text{NaNO}_3$. When dried at ordinary temperatures, water is lost and bismuthyl-hydroxide ($\text{BiO} \cdot \text{OH}$) remains, but when heated to 100°C . (212°F .) all the water is lost and the anhydrous oxide of bismuth is left.

Description.—Oxide of bismuth is a somewhat crystalline powder, of a dull yellow color, soluble, without effervescence, in mineral acids and in equal parts of nitric acid and water. It is not dissolved by water. Its solution in pure nitric acid should yield no precipitate, or at least should become but slightly turbid on the addition of silver nitrate solution. When heated to incipient redness it scarcely loses weight. At a high heat it melts to a brownish mass which, upon cooling, resumes a yellow color. Silver and lead oxides are among its impurities. They may be known by their appropriate tests.

Action, Medical Uses, and Dosage.—This agent resembles bismuth subnitrate in action, and may be used like it and in the same doses. It is, however, scarcely ever employed.

Related Compound.—BISMUTHI OXIDUM HYDRATUM (*N. F.*). *Hydrated oxide of bismuth.* *Formulary number, 13:* Bismuth subnitrate, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; nitric acid (*U. S. P.*), five hundred grammes (500 Gm.) [1 lb. av. 1 oz., 278 grs.]; water of ammonia (*U. S. P.*), six hundred grammes (600 Gm.) [1 lb. av., 5 ozs., 72 grs.]; sodium bicarbonate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; distilled water, a sufficient quantity.

Mix the bismuth subnitrate with two hundred cubic centimeters (200 Cc.) [6 fl. 3, 366 ml.] of distilled water in a quart flask, add four hundred and fifty cubic centimeters (450 Cc.) [15 fl. 3, 104 ml.] of nitric acid, and promote the solution of the salt by agitation, and, if necessary, by a gentle heat. Pour the solution into six thousand cubic centimeters (6000 Cc.) [about 64 qts.] of distilled water previously acidulated with fifty grammes (50 Gm.) [1 oz. av., 334 grs.] of nitric acid, and filter the liquid through absorbent cotton. Mix the water of ammonia with twelve thousand cubic centimeters (12,000 Cc.) [about 124 qts.] of distilled water in a glazed vessel of double that capacity, and pour into it, slowly and with constant stirring, the bismuth solution. Let the mixture stand during four hours so that the precipitate may subside, then pour off the supernatant liquid, and wash the precipitate four times more by decantation with distilled water, the sodium bicarbonate being dissolved in the last wash water. Pour the precipitate upon a wetted muslin strainer, and wash it with distilled water, until the washings run off tasteless. Transfer the strainer to a warm place, so that the precipitate may dry. Then rub the latter into powder, and keep it in well-stoppered bottles.

Note.—“Hydrated oxide of bismuth is sometimes demanded in the form of a creamy mixture with water, under the name of *Cremor bismuthi* or *Cream of bismuth*. This may be prepared by triturating 20 parts of the oxide with 80 parts of water” (*Nat. Form.*).

BISMUTHI SUBCARBONAS (U. S. P.)—BISMUTH SUBCARBONATE.

SYNONYMS: *Bismuth carbonate*, *Oxycarbonate of bismuth*, *Subcarbonas bismuthicus*, *Bismuthi carbonas* (*Br.*), *Bismuthum subcarbonicum*, *Bismuthyl carbonate*, *Carbonate of bismuth*.

Preparation.—The British process for making this preparation is as follows: “Take of purified bismuth, in small pieces, 2 ounces (av.); nitric acid, 4 fluid ounces (Imp.); carbonate of ammonium, 6 ounces (av.); distilled water, a sufficiency. Mix the nitric acid with 3 ounces of distilled water and add the bismuth in successive portions. When effervescence has ceased apply for 10 minutes a temperature approaching that of ebullition, and afterwards decant the solution from any insoluble matter that may be present. Evaporate the solution until it is reduced to 2 fluid ounces, and add this, in small quantities at a time, to a cold filtered solution of the carbonate of ammonium in 2 pints of distilled water,

continuously stirring during admixture. Collect the precipitate on a calico filter and wash it with distilled water until the washings pass tasteless. Remove now as much of the adhering water as can be separated from the precipitate by slight pressure with the hands, and finally dry the product at a temperature not exceeding 65.5°C . (150°F .)"—(*Br. Ph.*).

Most bismuth is contaminated with arsenic. The *U. S. P.* (1870) process was so constructed as to first purify the bismuth and the bismuth subcarbonate formed after purification. Such purification is not necessary in the British process, purified bismuth being used from the start. The *U. S. P.* (1870) process is as follows: "Take of bismuth, in pieces, 2 troy ounces; nitric acid, $8\frac{1}{2}$ troy ounces; water of ammonia, 5 fluid ounces; carbonate of sodium, 10 troy ounces; distilled water, a sufficient quantity. Mix $4\frac{1}{2}$ troy ounces of the nitric acid with 4 fluid ounces of distilled water in a capacious glass vessel, and having added the bismuth, set the whole aside for 24 hours. Dilute the resulting solution with 10 fluid ounces of distilled water, stir it thoroughly, and after 24 hours, filter through paper. To the filtered liquid, previously diluted with an equal measure of distilled water, slowly add the water of ammonia, constantly stirring. Transfer the whole to a strainer, and after the precipitate has been drained, wash it with 2 pints of distilled water, and drain it again. Then place the precipitate in a proper vessel, add the remainder of the nitric acid, and afterward 4 fluid ounces of distilled water, and set the solution aside. At the end of 24 hours filter through paper. Dissolve the carbonate of sodium in 12 fluid ounces of distilled water, with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and after the precipitate has been drained, wash it with distilled water until the washings pass tasteless. Lastly, press, dry it on bibulous paper with a gentle heat, and rub it into powder"—(*U. S. P.*, 1870). Owing to the fact that this compound occurs in market in both dense and light form, the question often arises concerning the reason for this difference in condition. If the final precipitation be made with hot distilled water the precipitate is dense, a pound of it being easily placed in a pint bottle. If the water be very cold, the precipitate dries light and may require a 24-ounce bottle.

Ammonium carbonate is preferable to sodium carbonate as employed in the *U. S. P.* process, because of the difficulty in removing all traces of alkali from the subcarbonate by washing out with distilled water as directed by the *U. S. P.* (1870).

Description and Tests.—The formula ascribed to this compound by the *British Pharmacopœia* is $(\text{Bi}_2\text{O}_3\text{CO}_2)_x \cdot \text{H}_2\text{O}$. No formula is given by the *U. S. P.*, which describes the salt as follows: "A white or pale yellowish-white powder of somewhat varying chemical composition, odorless and tasteless, and permanent in the air. Insoluble in water or alcohol, but completely soluble in nitric or hydrochloric acid, with copious effervescence. When heated to redness the salt loses water and carbon dioxide, and leaves from 87 to 91 per cent of a yellow residue which is soluble in nitric or hydrochloric acid, and blackened by hydrogen sulphide. If 3 Gm. of the salt be dissolved in just a sufficient quantity (about 4 Cc.) of warm nitric acid, and the solution poured into 100 Cc. of water, a white precipitate is produced. After filtering, and evaporating the filtrate on a water-bath to 30 Cc., again filtering and dividing this filtrate into portions of 5 Cc., these should respond to the following tests: On mixing one portion with an equal volume of diluted sulphuric acid, it should not become cloudy (absence of lead). If another portion be precipitated with a slight excess of ammonia water, the supernatant liquid should not exhibit a bluish tint (absence of copper). Other portions should not be affected by silver nitrate T.S. (absence of chloride), or barium nitrate T.S. (sulphate), nor yield, with hydrochloric acid, a precipitate which is insoluble in a slight excess of the latter (silver). If 1 Gm. of the salt be boiled with 10 Cc. of a mixture of equal parts of acetic acid and water, the solution cooled and filtered, and the filtrate freed from bismuth by hydrogen sulphide and again filtered, the last filtrate should leave no residue on evaporation (absence of alkalies and alkaline earths). On boiling 1 Gm. of the salt with 10 Cc. of potassium or sodium hydrate T.S., it should not evolve the odor of ammonia. If 1 Gm. of the salt be added to 10 Cc. of a mixture of equal parts of concentrated

sulphuric acid and water, tinged slightly blue with indigo T.S., on heating, the bluish tint should not be discharged (absence of nitrate). If 1 Gm. of the salt be ignited in a porcelain crucible, the residue, when cold, dissolved in 5 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), and a small piece of pure tin-foil added, no dark coloration or precipitate should be produced within 15 minutes (limit of arsenic)"—(U. S. P.).

Action, Medical Uses, and Dosage.—This agent was thought to be more soluble in the gastric fluids, and less liable to color the stools and to constipate, and was therefore introduced to take the place of subnitrate of bismuth. Its claims, however, have not led to its substitution for that agent. Dose, 10 to 40 grains in water.

BISMUTHI SUBNITRAS (U. S. P.)—BISMUTH SUBNITRATE.

FORMULA: $\text{BiONO}_2 \cdot \text{H}_2\text{O}$ (approximate). **MOLECULAR WEIGHT:** 304.71.

SYNONYMS: *Bismuthum subnitricum*, *Subazotas bismuthicus*, *Subnitrates bismuthicus*, *Magisterium bismuthi*, *Bismuthum hydrico-nitricum*, *Subnitrate of bismuth*, *White bismuth* (*Bismuthum album*, Br. Ph., 1864) *Oxy-nitrate of bismuth*.

Preparation.—The British process is essentially as follows: Take of bismuth, in small pieces, and free from arsenic or other impurities, 2 ounces, add this gradually in successive portions, to a mixture of 4 fluid ounces (Imp. meas.) of nitric acid, and 3 fluid ounces (Imp. meas.) of distilled water. When effervescence has ceased apply nearly a boiling heat for 10 minutes, and decant the clear solution from any remaining undissolved particles of the metal. Evaporate this solution to 2 fluid ounces and pour it into $\frac{1}{2}$ gallon of distilled water. Decant the supernatant liquid when precipitation has ceased, and agitate the sediment with $\frac{1}{2}$ gallon (Imp. meas.) of distilled water. After 2 hours, again decant, and, placing the product on a calico filter, press it with the hands, and dry it at the temperature not higher than 65.5°C . (150°F .).

Most of the metal may be dissolved without the application of heat, and only when there is no more action in the cold, must heat be used. If the metal be not added gradually, the action will be very violent, and at the same time a basic salt will be formed, which can with difficulty be redissolved. Concentrated nitric acid attacks bismuth with great violence, a vast quantity of red nitrous gas is emitted, and the metal is converted into a white oxide. When the acid is diluted the action is less violent, and the oxide of bismuth is dissolved by the nitric acid remaining in the solution, which has not undergone decomposition. The solution is colorless, and, on cooling, lets fall white crystals of oblique rhomboidal prisms, generally attached to each other in the form of stars of the ternitrate of bismuth ($\text{Bi}[\text{NO}_3]_3 \cdot 5\text{H}_2\text{O}$). When a large quantity of water is added to the clear solution, the ternitrate is decomposed, the subnitrate of bismuth precipitating in very fine white, silky, acicular crystals, while nitric acid remains in solution as represented in the following equation: $\text{Bi}(\text{NO}_3)_3 + \text{H}_2\text{O} = \text{BiO} \cdot \text{NO}_3 + 2\text{NO}_3\text{H}$.

Description and Tests.—The official description is as follows: "A heavy, white powder, of somewhat varying chemical composition, odorless and almost tasteless, and permanent in the air. Almost insoluble in water, and insoluble in alcohol; but readily soluble in nitric or hydrochloric acid. When heated to 120°C . (248°F .), the salt loses water (between 3 and 5 per cent of its weight); and when subsequently heated to redness, it evolves nitrous vapors, leaving from 79 to 82 per cent of its weight of a yellow residue which is soluble in nitric or hydrochloric acid, and blackened by hydrogen sulphide. When brought upon moistened blue litmus paper, the salt shows a slightly acid reaction. On dissolving 3 Gm. of the salt in 3 Cc. of warm nitric acid, no effervescence should occur (absence of carbonate), and no residue should be left (absence of insoluble foreign salts). If this solution be poured into 100 Cc. of water, a white precipitate is produced. If the filtrate, separated from this precipitate, be evaporated on a water-bath to 30 Cc., the liquid again filtered, and the new filtrate divided into portions of 5 Cc. each, these should respond to the tests for purity described under bismuthi subcarbonas. When further tested as described under bismuthi subcarbonas, the salt should be found free from alkalis and alkaline earths, and should give no reaction for ammonia. If 1 Gm. of the salt be heated, in a porcelain crucible,

until nitrous vapors cease to be evolved, the residue, when cold, dissolved in 5 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), and a small piece of pure tin-foil added, no dark coloration or precipitate should be produced within 15 minutes (limit of arsenic)"—(U. S. P.).

Subnitrate of bismuth was also formerly known by the names *Trimnitrate of bismuth* and *White oxide of bismuth*. Hydrogen sulphide, or the sulphides, blacken it; light also darkens it when it contains a portion of silver, or when, in a moist state, it is placed in contact with paper or other organic substances. Under the blowpipe it gives out nitric acid, and is reduced to the yellow oxide of bismuth, and if the heat be continued globules of metallic bismuth are obtained.

If any lead be present, diluted sulphuric acid gives a white precipitate with the solution in nitric acid. Arsenic, which may sometimes be present, may be detected by Marsh's test, or Bettendorff's test (see above). This preparation of bismuth was formerly known by the name of *magistery of bismuth*. Thallium is also stated to be frequently present in this salt, and M. Roussin has found it adulterated with phosphate of calcium, in the proportion of 28 to 100. There is no excuse for any pharmacist dispensing an inferior grade now, as it can be obtained to stand the official test of all American manufacturers.

Action, Medical Uses, and Dosage.—The insoluble preparations of bismuth have a feebly metallic taste, and, owing to the formation, it is claimed, of a sulphide, give a blackish coat to the tongue. While the subnitrate acts chiefly as a local agent, it must be remembered it is also somewhat absorbed, for it has been detected in the blood, and in the urine and other secretions. Very likely some of its specific influence is so exerted. The peculiar pasty taste upon the tongue and in the mouth, even after it has been administered in sugar-coated pills so as not to touch the buccal tissues, would tend to prove that a portion of it at least is absorbed. The chief action, however, is its protective agency upon the mucous linings of the stomach and intestines, allaying irritation by distributing over the surface a practically insoluble coating of unirritating material, and, while not a true astringent, it somewhat restrains the secretions, and acts as an absorbent of excess of acids present. It does not coagulate the gastro-intestinal mucus.

It has been considered a tonic and antispasmodic, but it is doubtful whether it possesses any such properties, though it may relieve *spasm* dependent upon an irritable condition of the mucous lining membrane of the stomach and the alimentary canal, upon which, as before stated, it appears to exert a sedative influence. When given in overdoses, subnitrate of bismuth produces unpleasant symptoms, as pain in the stomach, sickness, emesis, derangement of the bowels, giddiness, insensibility, etc., for which the remedies are, albuminous and mucilaginous draughts, milk injections, and warm fomentations. Perhaps diluted nitric acid would also be useful. These effects are said not to be produced by pure bismuth subnitrate, but have been attributed to impurities present in the drug. It is probable that some such effects are possible from even the pure drug. The long-continued use of the subnitrate of bismuth occasions symptoms of scorbutus. After death from disorders in which bismuth has long been used, a bluish discoloration in portions of the small intestines has been observed, and, owing to the formation of sulphides, the colic and rectal membranes may be stained black. The granular, amorphous, hydrated oxide of bismuth must not be used in medicine; it may be known from the subnitrate by the crystalline character of the latter, under the microscope.

Subnitrate of bismuth has a very soothing influence upon irritated mucous surfaces, or when these are in a state of chronic inflammation, and on this account it is very useful in some forms of *dyspepsia*, *chronic gastritis*, *heartburn*, *gastrodynia*, *water-brash*, *colliquative diarrhoea*, etc. Also in obstinate affections of the *genito-urinary organs*, in *chronic urethritis*, in *mucopurulent leucorrhoea*, and in *urethral injection* in *gonorrhoea*.

Its field of action in *gastro-intestinal disorders* is in those states of morbid sensitiveness as evidenced by the elongated, pointed, and red tongue, especially reddened at the tip and edges, uneasy sensations with heat in the stomach, or excessive gastric acidity, with nausea, vomiting, or eructations of acid or acrid fluids, and irritative diarrhoea. While an excellent agent in these conditions many prefer for the same the *Liquor Bismuthi*, or solution of ammonio-citrate of

bismuth. It is especially applicable to mild forms of *gastritis* and *gastro-intestinal catarrh* of young children. Give from 1 to 3 grains every four hours. It is one of the most certain agents for the pain of *gastric ulcer*, though less valuable where the *gastralgia* is purely neuralgic. The case of simple ulcer may be known by the pain coming on at once upon the ingestion of food. It does not cure *cancer of the stomach*, but the following combination gives as much relief as any form of treatment: R Bismuth subnitrate, grs. v to x; morphine sulphate, gr. $\frac{1}{16}$. Fiat, 1 powder. Sig. One powder every 6 hours (Locke). In *chronic diarrhœa* it has been found serviceable in doses of 5 to 20 grains every 1 or 2 hours; in the *diarrhœa* attending *typhus* and *phthisis*, 5 grains of the subnitrate combined with 3 grains, each, of magnesia and gum Arabic, has proved efficient—the dose to be repeated every 4 or 6 hours.

An excellent treatment for the *diarrhœa of phthisis* is that recommended by Prof. Locke (*Syllabus of Mat. Med.*, p. 375): R Bismuth subnitrate, ʒj; cinnamon water, flʒij. Mix. Sig. Dose, 1 or 2 teaspoonfuls every 3 hours. A milk diet, with 5 or 6 grains of this salt, was very effectual in the *chronic diarrhœa* from exposure so common to military life in the late civil war. It is also very valuable in the *dysenteries of hot climates*. In a long-standing case of *chronic gastritis*, accompanied with a harassing cough, laryngitis, great debility, night-sweats, loss of appetite, looseness of the bowels, and a fiery red tongue, the following mixture proved very beneficial: Take of fluid extract of cubebs, 1 fluid ounce; mucilage of gum Arabic, 2 fluid ounces; lupulin, subnitrate of bismuth, each, 2 drachms and 40 grains; essence of lemon, 1 fluid drachm. Mix. The dose was a teaspoonful 3 or 4 times a day, shaking it thoroughly each time previous to its exhibition. Bismuth is sometimes added to pills as a tonic. The action of the gases in the bowels causes the bismuth salt to appear black in the stools.

Subnitrate of bismuth has been found useful as a drying local application in *ulcers* and diseased mucous tissues with profuse discharges, as in *leucorrhœa*, *catarrh*, *gonorrhœa*, *gleet*, etc.; it may be applied upon the affected parts direct, through a tube, by powder spray, or suspended in water and injected. *Aphthæ*, *nursing sore mouth*, and *painful ulcers of the mouth*, due to gastric disorders, are relieved by it locally applied. It is an excellent dressing for *abrasions*, but should not be used on large wounded areas. *Excoriations* and *intertigo*, when red and painful, should first be washed with a weak solution of borax or alum, well dried, and then dusted with bismuth subnitrate. *Bed sores*, *superficial burns*, *chapped hands and lips*, *cracked nipples*, *fissured anus*, *vaginal and rectal prolapse*, *eczema*, *variola*, and *irritable ulcers* are conditions in which it is of great usefulness, and it may do good service in *uterine ulceration*, with acrid, offensive discharges. *Ulcers of the septum nasi* may be first cauterized with a mild caustic and then dressed with bismuth subnitrate, ʒij, in glycerin, flʒj. Prof. Locke recommends the following as a valuable cosmetic for *rough and pimpled skin*: R Bismuth subnitrate, ʒij; glycerin, flʒj; rose water, flʒii. Mix. Apply to face with a sponge after having washed well with Asepsin soap.

The dose of bismuth subnitrate is from 1 to 30 grains, 2 or 3 times a day, in powder, or mixed with mucilage. Where clearly indicated by the indications given, the small dose (2 to 4 grains) will usually be sufficient.

Specific Indications and Uses.—Elongated, red, pointed tongue, especially reddened at tip and edges; gastric uneasiness, with heat or pain from irritation; pyrosis, with acrid or acid eructations; intestinal irritation, with irritative diarrhœa; nausea and vomiting; gastric ulcer; morbid gastric sensitiveness. Locally, a soothing protective.

Bismuth and Its Salts.—BISMUTHUM. Symbol: Bi. Atomic weight: 208.9. Saxony furnishes the bulk of commercial bismuth. It is found there native in the metallic state, associated with nickel, cobalt, and argentiferous ores. Gold ore is sometimes associated with it, as in Colorado. Some bismuth is found in Australia, England, Texas, Connecticut, California, Mexico, Wyoming, Utah, Bolivia, France, and Hungary. Agricola (1520) was acquainted with bismuth, though Basil Valentine first differentiated it from other metals; but for a time afterwards it became confused with tin, antimony, lead, and zinc. Sometimes bismuth is found as an oxide, under the name of *Bismuth ochre*, but more frequently as sulphide (*Bismuth glance*) or telluride and sulphide ($[\text{Bi}_2\text{Te}_2]_2 + \text{Bi}_2\text{S}_3$), known in the latter case as the mineral *Tetradymite*. On account of its low melting point -288.3°C . (515°F .)—bismuth is readily obtained by melting the metal, by which means it is separated from its grosser impurities. When obtained

from the sulphide, the latter is first roasted to change it into oxide, and then heated with charcoal to reduce it to the metallic condition. As obtained by these processes it is known as *Crude bismuth*, and, besides other metallic bodies, it contains varying amounts of arsenic, iron, and copper. For medicinal use it must first be purified—that is, freed from arsenic, sulphur, and selenium (see below). Bismuth is a lamellated, crystalline, grayish-white metal, brilliant in lustre and exhibiting a decidedly roseate or pinkish tinge. Its crystals are rhombohedral, appearing very much as if cubical; brittle, easily comminuted; have a density of 9.83; fuse at 268.3°C . (515°F .); boil near 1100°C . (2012°F .); and, in the presence of hydrogen, may be distilled. In the air it tarnishes somewhat. When at a red heat the vapor of water is decomposed by it, and in the air it burns with a faintly-blue flame, changing to a brown oxide, becoming yellow when cool. Nitric acid attacks it energetically, dissolving it with the escape of reddish vapor. Diluted sulphuric and concentrated hydrochloric acids act upon it with much greater difficulty. Combined with other metals bismuth lowers their melting-points. An alloy, for example, consisting of 15 parts Bi, 8 Pb, 4 Sn, 3 Cd, called Wood's metal, has a melting point of 60°C . (140°F .).

BISMUTHUM PURIFICATUM.—"Take of bismuth, 10 ounces (av.); cyanide of potassium, $\frac{1}{2}$ ounce (av.); sulphur, 80 grains; carbonate of potassium, recently ignited, and carbonate of sodium, recently ignited, of each a sufficiency. Melt the bismuth in a crucible; add the cyanide of potassium and sulphur, previously mixed; heat the whole to low redness for about 15 minutes, constantly stirring; remove the crucible from the fire and let it cool until the flux has solidified to a crust. Pierce two holes in the crust and pour the still fluid bismuth into another crucible. Remelt this partially purified bismuth with about 5 per cent of a mixture of equal parts of the dried carbonates of potassium and sodium, heating to bright redness and constantly stirring. Remove the crucible from the fire, cool, and pour out the bismuth into suitable molds" (*Br. Ph.*). For the U. S. P. (1870) method of purification see process for preparing bismuth subcarbonate.

Another method of purification, directed by some Pharmacopœias, consists in fusing the powdered bismuth with potassium nitrate for about 1 hour, and boiling out the impurities (arsenate, sulphate and selenate of potassium) with water.

BISMUTHI BENZOAS, Bismuth benzoate.—A compound containing 27 per cent of benzoic acid and introduced as a substitute for salicylate of bismuth by Vigier. It decomposes in the alimentary tract, liberating the acid. To prepare it dissolve bismuth nitrate (100 parts), in glycerin (20 parts) and distilled water (60 parts). To this solution add another, prepared by dissolving sodium benzoate (76 parts) in distilled water (200 parts), employing heat.

BISMUTHI CERIUM SALICYLATE.—A powder of reddish-white color, soluble in neither water nor alcohol, introduced by Salaya, to be used in 5-grain doses in *enteritis, diarrhœa, and dysentery*.

BISMUTHI OXYCHLORIDUM (BiOCl). *Bismuth oxychloride, Bismuthyl chloride.*—This salt is produced by pouring into a nitric acid solution of bismuth a sodium chloride solution. It constitutes a powder known as *pearl white*, and is sometimes sold for bismuth oxide. It is easily dissolved by acids, but refuses to dissolve in water. If heated in closed tubes, it first turns yellow and then melts.

BISMUTHI LACTAS, Bismuth lactate.—This is a powder, white, not soluble in alcohol, and but slowly dissolving in water. It may be made by boiling with excess of sodium hydroxide bismuth nitrate (10 parts), thoroughly washing the resulting oxide with water, and mixing it (moist) with lactic acid (9 parts). Allow the mixture to digest, and dry upon the water bath.

BISMUTHI PHOSPHAS, Bismuth phosphate.—This is a white powder prepared by dissolving in a little nitric acid 5 parts of bismuth subnitrate, and slowly pouring the solution into one of sodium phosphate (8 parts). Preferred by some to other bismuth salts on account of its greater insolubility. Dose, 1 to 5 grains.

BISMUTHI NITRAS (Bi[NO₃]₃·5H₂O), Bismuth nitrate, Bismuthous nitrate.—Also known as *Bismuth ternitrate, Bismuthum trinitricum, and Normal bismuth nitrate.*—The manner of forming and purifying this salt has already been described. It forms large prismatic crystals without color, pronouncedly acid to the taste, and soluble in glycerin. Such a solution, when fresh, may be mixed in all amounts with water without precipitation (Dr. Balmano Squire). The salt is decomposed when added primarily to water, a basic nitrate resulting. The crystals melt in the crystal-water at near 80°C . (176°F .); at 120°C . (248°F .), a portion of its acid is lost, while at 260°C . (500°F .) the whole of the acid is dissipated, an oxide (Bi₂O₃) being left. A *glycerite of bismuth nitrate* was proposed by Morehead, in 1877, in which bismuth nitrate (2 ounces), was to be dissolved without heat, in sufficient glycerin to produce 8 ounces of finished product. A perfect solution is produced, which may be diluted with water as desired.

BISMUTHI SALICYLAS (Bi[C₇H₅O₂]₃·Bi₂O₃), Bismuth salicylate.—Duyk's process is to prepare bismuth oxide (Bi₂O₃), from pure bismuth subnitrate by means of ammonia water, and digesting the moist oxide with salicylic acid, wash the product with cold water, and dry the magma at a low temperature. It forms a tasteless, odorless, non-crystalline powder, having the color of cream. It is dissolved by acids, but not by water, alcohol, glycerin, or ether. This agent is not superior to the subnitrate, but has been used in *painful gastric affections and diarrhœa*. Extraordinary claims have been made for it in *typhoid fever*. Large doses of 10 to 30 grains, 3 times in 24 hours, are reputed efficient in *chronic catarrh of the stomach*. The nitro-salicylate of bismuth is reputed a heart stimulant.

BISMUTHI SUBIODIDUM (BiOI), Bismuth subiodide, Bismuthyl iodide, Bismuth oxyiodide.—This is a brown-red or bright-red powder, which may be crystalline or amorphous, according to the manner in which it is produced. When bismuth nitrate, suspended in water, is boiled with iodide of potassium, the crystalline salt is formed. It may be obtained amorphous by taking bismuth nitrate solution in such a proportion that the salt does not precipitate, and simply

warming it with potassium iodide. This agent was introduced as an antiseptic to take the place of iodoform, and is used like bismuth subnitrate in *gastric disorders*, being particularly adapted to *chronic ulceration of the stomach* and other parts. Dose, 5 to 10 grains.

BISMUTHI SUBGALLATIS ($C_6H_2[OH]_3.COOBi[OH]_2$), *Bismuth subgallate*, *Bismuth gallate*, *Bismuthi gallicum basicum*. **DERMATOL**.—To prepare it dissolve in glacial acetic acid (30 parts), bismuth subnitrate (15 parts); then add 250 parts of water and filter the solution. Now prepare a second solution of gallic acid (5 parts), in water (250 parts), and while still warm add the warm solution, with constant stirring, to the filtrate first prepared. Decant the supernatant fluid, wash the precipitate until the presence of nitric acid is no longer detectable, and dry the product at a heat of $100^\circ C.$ ($212^\circ F.$). Dermatol is an impalpable powder, without odor, and having a saffron-yellow color. In the air it remains permanent, and the common solvents do not effect its solution. Though accredited with perfectly non-toxic properties, a peculiar intoxication is reported to have resulted from dermatol. It was introduced as an iodoform substitute, but is not so powerful a germicide as that agent. It is astringent, absorbent, sedative, and protective. Internally it has been given in doses of from 5 to 30 grains in *chronic diarrhæa* and *dysentery*. Locally it may be applied to parts after active inflammation has subsided, as in *wounds, ulcerations, abscesses, burns, herpes, eczemas*, etc.—in short, in the conditions for which iodoform is generally employed.

BISMUTHI VALERIANAS ($Bi[C_2H_3O_2]_3$), *Bismuth valerianate*, *Valerianas bismuthicus*.—Valerianate of bismuth is a white, amorphous powder, with a strong valerian odor. It is made by dissolving pure metallic bismuth in nitric acid, saturating any excess of the acid with carbonate of sodium, and then adding a solution of valerianate of sodium to the bismuth solution as long as any precipitate continues. Collect the powder on a filter, wash and dry it. It has been highly recommended in *dyspepsia* with nervous irritability, *gastrodynia*, and in *neuralgic affections*, in doses of from $\frac{1}{2}$ grain to 2 grains, repeated 3 or 4 times a day.

BISMUTHI TANNAS, *Bismuth tannate*, *Bismuthum tannicum*, *Tannus bismuthicus*.—Tannate of bismuth is prepared by treating 44 parts of crystallized nitrate of bismuth with water, at the same time adding a slight excess of caustic soda; collect the white hydrated precipitate (hydroxide of bismuth), on a filter, carefully wash it, and then triturate it in a mortar with 29 parts of pure tannic acid. Dilute the magma with water, throw it upon a filter, wash it, dry it in the air, or at a very moderate artificial heat, and reduce it to powder. It is a yellowish, insoluble powder, without taste, and may be given in pills, or suspended in a mucilaginous fluid. The dose is from 30 to 60 grains. It has proved remarkably efficient in the treatment of both *acute and chronic diarrhæa*; it was formerly used in *ophthalmia*, *leucorrhæa*, and *gonorrhæa*.

BOLDUS.—BOLDO.

The leaves of *Peumus Boldus*, Molina, (*Boldoa fragrans*, Gay).

Nat. Ord.—Monimiaceæ.

COMMON NAME: *Boldo* or *Boldu*.

ILLUSTRATIONS: *Bot. Reg.*, Plate 57; Bentley and Trimen, *Med. Plants*, 217.

Botanical Source.—*Peumus Boldus* (*Bot. Reg.*, Plate 57, and Bentley and Trimen, *Med. Plants*, 217), is an evergreen, fragrant shrub, from 15 to 20 feet high, and native of the mountainous regions of Chili. The leaves are opposite, coriaceous, and on leaf-stalks about $\frac{1}{2}$ inch in length. The flowers are in loose, terminal, dicecious cymes of about 12 flowers each, on slender, pubescent pedicles. The petals are generally 7, strap-shape, and about $\frac{1}{2}$ inch long, of a light-yellow color, and somewhat twisted. The male flower has numerous recurved stamens, with slender filaments, which are hairy at the base. The fruit is a small orange-green, 1-seeded drupe, which is aromatic and edible.

Description.—The leaves (Fig. 49), as found in commerce, are thick, firm, of a light-green color, and covered with numerous glandular points on the upper surface. They are about 2 inches long, two-thirds as wide, and oval or elliptical in outline; have a rounded base, and a very obtuse apex. The edges are entire, and slightly recurved. The veins are pinnate, and prominent on the under side of the leaves. The odor of the leaves somewhat resembles that of wormseed, and the taste is nauseating and disagreeable.

History and Chemical Composition.—In 1782, Molina described this shrub, under the name *Peumus Boldus*; in 1794, Ruiz and

Fig. 49.

Leaf of *Peumus Boldus*.

Pavon described the same plant under the name *Rulzia fragrans*; in 1809, Jussieu classed the plant under the name of *Boldoa fragrans*; finally, in 1869, M. H. Baillon presented a complete history of the plant under the name *Peumus Boldus*, which name it still retains. Boldo was introduced to the profession by Dujardin-Beaumez and C. L. Verne, about 1872, and in the same year E. Bourgoïn and C. Verne obtained from the leaves a volatile oil, and an alkaloid to which the name *boldine* or *boldina* was given. The plant also contains essential oil, citric acid, lime, sugar, gum, tannin, and a quantity of thick, black, aromatic substances, probably due to oxidation of the oil; these constituents have no medicinal virtues. *Boldoglucin*, a narcotic alkaloid, was isolated by Chapoteaut.

The plant attracted but little attention until 1875, when Prof. Bentley exhibited it before the Pharmaceutical Society of Great Britain, and Dr. Miller brought it before the Philadelphia Pharmaceutical meeting. After this, some little demand was created for it, and even at exorbitantly high prices, small amounts were sold in this country. At present the demand is limited, and the price is reasonable. The virtues of the drug, whatever they may be, are evidently derived from the essential oil and the alkaloid.

Boldine is obtained by extracting the leaves of the plant with alcohol, distilling the alcohol, and exhausting the residuum with acidulated water (acetic acid preferable), precipitating with ammonia, and purifying by solution in ether. It is a tedious operation to obtain the pure alkaloid. *Boldine* is crystallizable, soluble in alcohol, ether, chloroform, benzol, and benzin. The diluted acids dissolve it, from which solution ammonia, in slight excess, precipitates the alkaloid as an amorphous mass. It is sparingly soluble in water, to which it imparts a bitter taste, and gives an alkaline reaction. Nitric and sulphuric acids yield a red color when boldine is added to them. The best agent to extract the medicinal principles of the leaves is alcohol, and the addition of water to the menstruum, even in small amount, is objectionable.

Action, Medical Uses, and Dosage.—This agent is a stimulant to the circulatory organs and nervous structures. It is quieting and soothing, producing in full doses drowsiness. *Cerebral excitation* is said to be controlled by boldo and boldoglucin, refreshing sleep following. Boldo was sent from Chili as an efficient agent in *hepatic diseases*, but its effect appears to be that of a gentle, diffusible stimulant, probably useful to a certain extent in *gastric debility*, *incipient dyspepsia*, *anemic conditions*, etc. It is of value in *painful digestion* with nervous irritability, and in *gastrodynia*. In these cases the alcoholic solution is undoubtedly the preferable one. A wine, elixir, and syrup have also been prepared, but they possess no advantages over the tincture, which may be used in doses of from 5 to 20 drops in some agreeable vehicle. One part of the leaves to 5 parts of alcohol, at 60 per cent, forms a deep-red, bordering a little on green, bitter tincture. Boldine may be given in doses of from 1 to 5 grains. The essential oil, in doses of from 3 to 5 drops, in capsules, has been recommended in *subacute inflammations* and *catarrh of the urinary passages*; but it certainly possesses no superior advantages over turpentine, copaiba, and other resinous balsams. A very moderate use of the oil will, in a few days, impart the strong odor of the leaves to the urine, which fluid will redden under the action of diluted sulphuric acid.

Specific Indications and Uses.—Gastric pain, nervousness, debility and jaundice.

Related Species.—*Atherosperma moschatum*, Labillardière. *Sassafras tree*, Australia. All parts of this tree have a nutmeg-like odor. Tannin and a bitter alkaloidal body (*atherospermine*) have been obtained from the bark. The latter is an amorphous, white powder, sparingly soluble in ether, but dissolving freely in chloroform or alcohol. The bark is reputed antisyphilitic, antiscorbutic, and tonic. It renders difficult expectoration easy, reduces the pulse rate, and is sedative to an overacting, irregular heart. The Australian Bushmen employ a diet-drink prepared from it, in *rheumatism* and *secondary syphilis*. Graves personally found it of much value in *chronic bronchitis*.

Daphnandra repandula, F. von Mueller.—A toxic alkaloidal principle is derived from this plant, which is said to be, in some respects, the antagonist of strychnine. It is soluble in water. Muscular paralysis is produced by its local application. It has antiputrefactive qualities, and will deodorize tainted meats. The bark is rich in alkaloids which, when pure, are crystalline and colorless. It checks the growth of the yeast plant (*Torula cerevisiæ*). *Daphnandra micrantha*, Benthams (*Atherosperma micranthum*, Tul.), is identical with the foregoing in its action (*P. J. and Trans.*, 1887). It is intensely bitter, and is used as a tonic by the Australians.

BOLETUS.—WHITE AGARIC.

The fungus *Polyporus officinalis*, Fries (*Boletus laricis*, Jacquin; *Boletus purgans*, Persoon).

Nat. Ord.—Fungi.

COMMON NAMES: *White agaric*, *Larch agaric*, *Purging agaric*.

Description.—White agaric (*Agaricus albus*) is in masses varying from the size of an ordinary apple to that of a large nutmeg-melon; its shape somewhat resembles a horse's hoof; it is reddish-grey or yellowish externally, whitish internally, and of a spongy, friable consistence; hymenium concrete; substance of the hymenium consisting of subrotund pores, with their simple dissepiments; pileus corky-fleshy, ungulate, zoned, smooth; pores yellowish; it has a feeble odor, and a bitter, acrid, somewhat sweetish taste.

History.—The various medicinal substances, included under the elastic name *Agaric*, are obtained from various plants of the fungous tribe. These plants afford a great diversity of form and structure, being in their simplest character little articulated filaments composed of chains of cellules, as in the mildew of the rose bush, and in moldiness, *mucor*; again, they may present an even and imperforate surface, and another separated into plates or cells, in which the sporules are deposited. They absorb a great amount of oxygen with evolution of hydrogen and carbonic acid gas, and contain considerable proportions of nitrogen. They are destructive to nearly all organic matter upon which they grow. According to recent nomenclature, "the genus *Boletus*, as now constituted, includes only *fleshy* species, with a hymenium composed of *separable tubes*. Those species formerly included in *Boletus* (many of which have corky or woody tissues) and the hymenium of which is composed of pores *not separable* from the pileus or from each other, form the genus *Polyporus*."

The *Polyporus officinalis*, Fries (*Boletus laricis*, Jacquin), is procured from Asia, Corinthia, Russia, and Central America, where it is found growing upon the larch. It is collected in August and September, deprived of its outer covering, and then dried and bleached in the sun. It is exceedingly difficult to pulverize in a mortar, but may be readily powdered by grating through a sieve.

This substance is generally known in Eclectic medicine as *Boletus laricis*, hence that term is here retained though the fungus is properly a *Polyporus*, and should be known by that name.

Chemical Composition.—This fungus is remarkable for the great amount of *resinous* matter it contains, running as high as 79 per cent. Various resinous and crystallizable substances have been differentiated therefrom by several investigators. Jahns, in 1883, isolated *agaric acid* from the alcoholic extract of the fungus, for which he found the formula $C_{28}H_{40}O_5 + H_2O$. This formula and the bibasic nature of the acid was confirmed by Schmieder, in 1886, who made an exhaustive study of the chemistry of this fungus. Petroleum ether [boiling point, $45^\circ C.$ ($113^\circ F.$)], abstracted from the finely-powdered drug a fluorescent oil, from which crystals of *agaricol* ($C_{28}H_{40}O$) were separated, melting at $223^\circ C.$ ($430.7^\circ F.$). *Cholesterin* was obtained from the mother liquor; also two solid hydrocarbons, $C_{28}H_{48}$ and $C_{28}H_{54}$. The residue from the treatment with petroleum ether yielded to boiling water sugar, phosphoric, malic, and tannic acids. Boiling alcohol then abstracted 5 resins, the principal of which was a *red resin* ($C_{28}H_{48}O_2$), melting at $88^\circ C.$ ($190.4^\circ F.$), which is stated to be the actively purging principle of the drug. The fungus contains also a peculiar kind of cellulose, to the extent of 10 per cent, and ash, which mostly consists of the phosphates and carbonates of potassium and magnesium (Flückiger, *Pharmacognosie*, 1891). *Agaric acid* is official in the *German Pharmacopœia*, under the name of *Agaricinum*, and is described as a "white powder having a faint odor and taste, fusing at about $140^\circ C.$ ($284^\circ F.$) to a yellowish liquid; upon further heating evolving white fumes, and charring while giving off a caramel-like odor. It is little soluble in cold water; swells up in hot water and dissolves upon boiling, forming a frothing opalescent liquid, which faintly reddens litmus, and becomes strongly turbid upon cooling. Agaricin is soluble in 130 parts of cold, or 10 parts of hot alcohol; more easily soluble in warm acetic acid; very little soluble in ether; scarcely soluble in chloroform.

Caustic potash dissolves it, forming a liquid which, upon shaking, forms a heavy froth"—(*Ger. Pharm.*).

Action, Medical Uses, and Dosage.—*Polyporus officinalis* and the *P. pinicola* (see below), in doses of 3 or 4 grains of the powder, repeated every 3 or 4 hours, or of the concentrated tincture in doses of 5 drops, have both been found valuable in the cure of obstinate and long-standing intermittents, and other diseases common to malarial districts, as *obstinate bilious remittent fever*, *chronic diarrhœa*, *chronic dysentery*, *periodical neuralgia*, *nervous headache*, *ague cake*, and *increased flow of urine*. They have likewise proved useful in long-standing jaundice, and in the *chills* and *fever* common among consumptive patients.

The dust of the *Larch agaric* is irritating to mucous surfaces, causing tears when it enters the eyes, and sneezing, cough, and nausea, when the nostrils are exposed to it. It has been used in $\frac{1}{2}$ drachm or drachm doses as a purgative; in larger doses as an emetic. Small doses, unless long continued, check *diarrhœa*, as well as *excessive broncho-pulmonary secretions*; hence the value of agaric and agaricin in *phthisis*. Boletus is also said to arrest the mammary secretion. In doses of 3 to 10 grains, gradually increasing to 60 grains in the course of the 24 hours, it has been found efficient in arresting the *nocturnal perspiration of consumptives*. For this purpose, however, *agaricin* (see below) is now preferred. Owing to its power over the sympathetic and spinal nervous system, certain cases of *epilepsy* and *chorea* have been controlled by it; and in *neuralgia* and *insanity* it has been found of value where nutrition was imperfect and the cerebral circulation feeble. As a remedy for *ague* it is adapted to those cases presenting alternate chills and flushes of heat, with heavy bearing-down pains in the back. The patient perspires freely at night and has a yellow-coated tongue, bitter taste, poor appetite, slight fever, and has for some time been experiencing a dull, languid feeling. Not only does it check phthisical night-sweats, but it also controls the rapid circulation and reduces the hectic fever. Externally, it has been used, together with the *Agaric of the oak* (*Polyporus fomentarius*, Fries) as a styptic, and is said to restrain not only venous, but arterial *hemorrhages*, without the use of ligatures; it does not appear, however, to possess any real styptic power, or to act otherwise than dry lint, sponge, or other soft applications. Prepared with nitre as for tinder, it has been used as a species of moxa.

AGARICIN (*agaric* or *agaricinic acid*) is irritant to the gastro-intestinal tract, occasioning, in doses of 5 to 15 grains, purging and vomiting. Upon the lower animals it depresses the nervous, respiratory, and circulatory systems. According to Riegel $\frac{1}{2}$ grain of agaricin is equal, as an antihydrotic, to $\frac{1}{2}$ grain of atropine. In doses of $\frac{1}{16}$ to $\frac{1}{8}$ grain it has been remarkably effectual in *colliquative sweating*, especially in *phthisis*, where it also allays thirst and controls the cough and diarrhœa in some cases. Long continued use of it will produce looseness of the bowels.

Tincture of boletus, 1 to 5 drops; specific boletus, fraction of a drop to 5 drops; agaricin, $\frac{1}{4}$ to $\frac{1}{2}$ grain.

Specific Indications and Uses.—Ague, with alternate chills and flushes of heat, with heavy bearing-down pain in the back (*Sp. Boletus*, gtt. x to aqua, f3iv. Mix. Teaspoonful every 2 hours). Stimulant to nervous system, when nutrition is impaired and cerebral circulation feeble; colliquative sweats.

Related Fungi.—*FUNGUS CHIRURGORUM*, or *Surgeon's agaric*, known also as *Agaricus* (or *Boletus*), *chirurgorum*, and as *Spunk*, *Touchwood*, and *Tinder*, is the *Polyporus fomentarius*, Fries. A hoof-shaped, obliquely triangular, sessile fungus found on oak and beech trees in South and Central Europe, freed of its hard rind and hymenial, tubular spores, cut into slices, immersed in water, and afterward boiled in a weak, alkali solution, washed again, and finally beaten until soft and pliable. When cut into slices, beaten, soaked in a solution of nitre, and dried, it forms an inflammable substance known as *spunk*, *amadou*, or *German tinder*.

Surgeon's agaric is tasteless, practically odorless, and soft. It is in velvety, glossy, and cinnamon-colored flat pieces. It is exceedingly light, tough, porous, and elastic, and has long been valued to arrest local *hemorrhages*, small in amount. By insinuating it between the nail and the flesh, and securing it with adhesive strips, it is one of the best of substances for use in the treatment of *ingrown toe-nail*.

Polyporus igniarius, Fries, or *Agaric of the oak*, is a fungus found on oak, cherry, willow, plum, and other trees. When young it is soft, but gradually becomes hard and woody. In shape it somewhat resembles the *Polyporus officinalis*; its upper smooth surface is marked with dark circular ridges, and its under surface is very porous and of a yellowish-white color. It is tasteless and inodorous.

Polyporus pinicola grows upon the pine, birch, tamarac, fir, and similar trees. With absolute alcohol, the fresh fungus forms a dark-red, intensely bitter tincture.

Amanita muscaria, Persoon (*Agaricus muscarius*, Linné). *Fungus muscarius* or *Fly agaric*.—This poisonous European fungus, which makes its growth in the autumn months, usually in pine woods, derives its common name from the fact that when infused in milk it is used for the purpose of destroying flies. The stem or stalk is white, thick, and tuberous or bulbous at the base, where there are also scales. It is about $\frac{1}{2}$ of an inch thick, and from 3 to 6 inches high. The cap or pileus, which is at first spherical, flattens out or becomes convex while growing, and when full grown is either flattish or depressed, and from 4 to 8 inches broad. The cap is usually scarlet or orange in color, though it has been found to vary to crimson, light-brown, greenish-yellow, or even white. Internally the fungus is yellowish. White, angular warts are scattered upon the surface of the pileus, and when moist these are sticky. The under surface has broad, white, lamellated gills, or hymenium. An acrid, burning taste and an unpleasant odor characterizes this species. Apoiger (1851) considered the toxic principle to be a crystallizable acid, while Letellier regarded *amanitin*, a brown, tasteless, non-crystalline glucosid, to be the active constituent. An alkaloid, *muscarine* ($C_8H_{14}NO_2$), was isolated, in 1869, by Schmiedeburg and Koppe, *choline* ($C_8H_{14}NO_2$), also a constituent of hops, beer, bile, brain, and herring brine, being associated with it. The latter body is probably identical with Harnack's (1876) *amanitine*. *Muscarine* (sometimes wrongly termed *amanitine*) is an exceedingly deliquescent, crystalline alkaloid, without color or odor; sparingly dissolved by chloroform, but not by ether. It unites with acids to produce deliquescent salts. It dissolves readily in water and alcohol. Kobert, in 1891, pointed out the existence in this fungus of another alkaloid, *pilocarpin*, this being the physiological opposite of *muscarine*. A. B. Griffith, in 1896, gave the name *amanitine* to the red, amorphous pigment of the fungus, insoluble in water, and soluble in chloroform and ether. *Fly agaric* once had a reputation as a remedy for *epilepsy*. *Chorea* is treated with it by homeopaths, and it was also used in *chronic skin affections*. That it possesses undoubted power over the nervous system seems well established, and its use is suggested in *spinal irritation* and *typhoid conditions* characterized by "tremor, restlessness, and desire to get out of bed" (Webster). Prof. Scudder (*Specific Medication*), who suggested a tincture of the fresh fungus prepared with strong alcohol, wrote: "Probably the best defined indication for this remedy is involuntary twitching of the muscles of the face, forehead, and even of the eyes, so that objects are not seen well because they seem to move; drawing of the tissues of the forehead and nose. Pressing pain in the occiput and an inclination to fall backward is also a very good indication." Tincture, gtt. j. to aqua $\frac{3}{4}$ iv. Dose, 1 teaspoonful. The principal use that has been made of this fungus is to control *colliquative night-sweats* from debilitating diseases, and profuse sweating during the daytime. The extract, in doses of 5 drops of a 1 per cent solution, has been employed. *Muscarine* may be used.

Muscarine is usually employed in the form of a sulphate or nitrate. It is an exceedingly energetic poison, and is antagonistic to atropine, and is sometimes used instead of eserine in poisoning by the latter. Profuse ptyalism, weeping, vomiting, depressed circulation, difficult breathing, muscular weakness, paralysis, and death are the effects of a toxic dose. Before death the pupils, which are minutely contracted, dilate. Tetanic contractions of the spleen, bladder, and intestines occur, and the latter finally relax, when violent peristaltic movements ensue. *Muscarine* is used in *colliquative sweats* and in *diabetes insipidus* in doses of $\frac{1}{16}$ to $\frac{1}{8}$ grain.

For the poisonous effects of *Amanita* species, see below (*Amanita phalloides*).

Amanita phalloides, Fries. *Death-cup* (see illustration, *Your Book of U. S. Agric. Dept.*, 1896, p. 144).—This is reputed the most toxic of all the fleshy fungi. It resembles in general shape the common mushroom, which, however, lacks the basal, cup-like appendage of the death-cup. It resembles also the *Amanita muscaria* (see above), from which it may be distinguished by the more brilliant coloring of the latter. This fungus grows in the medium elevations and low lands of nearly all parts of the United States and in Europe. The white stem when young is more or less pithy, but as the fungus grows it becomes somewhat fistulous. The young plant is entirely enclosed in a volva, which breaks circumscissally as the plant expands, leaving at the base, as a remnant of the volva, a cup-like appendage, which is characteristic. The cap, unless it should bear fragmentary remains of the volva, is usually smooth and satin-like, and when moist, viscid. It varies in color, and though most generally white or yellowish, it may be green, or if grown in deeply shaded situations, spotted. It has white gills and spores. The fungus varies in height from 3 to 5 inches. No bad taste gives warning of the dangerous character of this fungus, of which but a small portion may kill. A boy of 12 met death from a third of a middle-sized raw pileus. Out of 51 cases of poisoning by this plant, 76 per cent were fatal, and during the summer of 1893, 25 deaths in the United States alone, were attributed to species of *amanita*. A half day or more may elapse after swallowing the fungus before any discomfort is felt by the victim. Then follow severe intestinal pain, nausea and vomiting, and excessive diarrhoea of the rice-water type, symptoms closely resembling Asiatic cholera. These symptoms persisting, death may take place in from 2 to 4 days, consciousness being retained to the last.

That *muscarine* was the chief cause of the toxic symptoms has been maintained for several years. It has been observed, however, that in fatal cases the symptoms were different from those caused by *muscarine* alone, and that they were not antidoted by atropine, which is antagonistic to that alkaloid. Later investigations, in 1891, by Kobert, of Dorpat, seem to establish the fact that the chief toxic principle is a tox-albumin, not unlike *abrin* (see *Abrus precatorius*), and other poisonous albumins, such as have been found in rattlesnake and insect venom, barbadose nut, castor-oil bean, etc. To this body the name *phallin* has been given. It is without odor and taste, and is easily coagulated by heat. Its death-dealing action

appears to reside in its power to dissolve the red-blood discs, thereby allowing the blood serum to escape by way of the alimentary canal. Salt solution dissolves phallin, removing it from the fungus, but after having been swallowed there is no known antidote. For an excellent article, from which this note is compiled, see "*Some Common Poisonous Plants*" (illustrated), by V. K. Chesnut, in *Yearbook of U. S. Agric. Dept.*, 1896, p. 144.

Lycoperdon Bovista, Linné (*Lycoperdon giganteum*, Batsch; *Bovista giganteum*, Nees). *Giant puffball*.—Yellow or deep-brown, oboconical or subglobular masses having a spongy interior. They sometimes attain a width of 2 feet. It furnished the *Fungus chirurgorum*, much used at one time as a local hæmostatic. Said to be anodyne and antiseptic, and to be a good application to *cancerous growths*, to allay pain and check bleeding. Porcher, from personal experience, declared Giant puffball to possess some narcotic power. A tincture has been used in *nervous affections* and the dry powder in *intertrigo*. The fumes from burning this common puffball are narcotic and anæsthetic, but no practical application of them has been made. In 1853, Dr. B. W. Richardson, acting upon the suggestion that bees were stupefied by the fumes of this fungus, experimented upon and narcotized and anæsthetized several animals, from one of which he painlessly removed a tumor. If carried too far the inhalation produced death, respiration being paralysed. No congestion was produced. When death was not produced the animal slowly recovered, and even after the narcotism had passed off the perception of pain was for a time abolished. These effects have been attributed to carbonic oxide, the gas given off when the puffball is burned.

Elaphomyces granulatus, Fries (*Lycoperdon cervinum*, Linné; *Scleroderma granulatus*, Persoon.) *Hart's truffle*, *Puffball*.—Walnut-sized, warty, brown fungus, with a purple-brown interior. Stimulant.

Pachyma Cocos, Fries (*Lycoperdon solidum*, Gronovius). *Tuckahoe*.—A peculiar formation found upon fir-tree roots, believed to be an alteration of the same, produced by a fungus. It is found in the southern portion of the United States, where it is known as *tuckahoe*, or *Indiana bread*. In China, where it also grows, it is called *fuh-ling*. It is a long or irregularly globose body, often weighing many pounds. It has a rugose, ashy-black surface, and a whitish, firm, but apparently spongy interior. It has a starchy appearance internally, and breaks into irregular fragments. It contains pectose, glucose, gum, cellulose, nitrogen, and salts.

Tuber cibarium, Sibthorp (*Lycoperdon Tuber*, Linné). *Truffle*.—An edible tuber growing beneath the surface of the ground. Walnut-sized, subglobose, warty, and blackish externally, with a fleshy, marbled (white and brown) interior.

BROMUM (U. S. P.)—BROMINE.

SYMBOL: Br. ATOMIC WEIGHT: 79.76.

Source, History and Preparation.—Bromine is one of the two known liquid elements. It was first obtained by Balard (1826), who prepared it from the mother-liquor left in the production of sea salt. It is always found in combination, never in a free condition. It exists in sea water principally in bromides of magnesium and sodium. The greater share of bromine, however, is prepared from the bittern of salt works. Formerly the supply came from the mineral springs of Europe and the Stassfurt potash-beds, but at the present time immense quantities are prepared from saline springs, along the Kanawha River, in West Virginia. Quite large quantities are prepared also in Pennsylvania, while in recent operations in Michigan bromine is said to be produced in as great amount as in West Virginia. Bromine may also be prepared from seaweeds. In sea water the bromides usually accompany chlorides. Balard pointed out its relationship to iodine and chlorine. Bromine is prepared for commerce by mixing sulphuric acid, manganese dioxide, and the evaporated mother-liquor of the salt springs in a stone retort and applying heat. By this process decomposition takes place, with the liberation of chlorine, which, in turn, decomposes the soluble bromides present, forming chlorides, allowing the bromine to distill over and condense. The greater portion of bromine is used in making the medicinal bromides and in photography. A portion, however, is used in the production of certain aniline dyes (which see).

Description and Tests.—Bromine in bulk appears almost black, but shaken so as to strike the sides of the bottle, it exhibits a ruby-red color. According to the U. S. P. it "should be kept in glass-stoppered bottles, in a cool place," and respond to the following description and tests:

"A heavy, dark brownish-red, mobile liquid, evolving, even at ordinary temperatures, a yellowish-red vapor, highly irritating to the eyes and lungs, and having a peculiar suffocating odor, resembling that of chlorine. Specific gravity: 2.990 at 15° C. (59° F.). Soluble in 30 parts of water at 15° C. (59° F.), and readily soluble in alcohol or ether (with gradual decomposition of these liquids);

also in carbon disulphide, and in chloroform, with a deep reddish-yellow color. On exposure to air or to heat it is completely volatilized. It destroys the color of solutions of litmus and indigo, and imparts a yellow color to solution of starch"—(*U. S. P.*).

At about -22°C. (-7.6°F.) it freezes, forming a leaden-colored crystalline solid. Its boiling point is near 62.7°C. (145°F.). From a saturated solution of bromine, at a little above 0°C. (32°F.), a crystalline body, having the formula $\text{Br} \cdot (\text{H}_2\text{O})_n$, is produced. Organic material is decomposed by bromine, while in dilution in water, like chlorine, though in a lesser degree, it acts as a decolorizer. A yellowish-brown color is imparted by it to starch. Aqueous solutions of bromine decompose in the sunlight, with the liberation of oxygen and the production of hydrobromic acid. This is true also of its solutions in alcohol and ether. Commercial bromine often contains, as impurities, carbon bromide, rendering its boiling point higher, and chlorine, which reduces its boiling point. Iodine is rarely present. Owing to its intensely poisonous vapor workmen, when handling bromine, always stand in a draught of air so that its fumes may be blown from them and keep near at hand a quantity of ammonia (which is its best antidote) to inhale in case it is breathed into the lungs. Bromine forms hydrogen salts, derivatives of hydrobromic acid, e.g., BrNa , called *bromides*, and oxy-salts of the type BrO_2Na , called *bromates*, or of the type BrONa , called *hypobromites*.

"If bromine be added to an excess of potassium or sodium hydrate T.S., it should combine to form a permanently clear liquid, without the separation of oily drops, or the development of an odor resembling that of chloroform (absence of bromoform or other organic bromine compounds). If an aqueous solution of bromine be shaken with a slight excess of reduced iron until it becomes nearly colorless, the filtered liquid, on the addition of a small amount of ferric chloride and of starch T.S., should not assume a blue color (absence of iodine). If 1 Cc. of a saturated aqueous solution of bromine be diluted with 9 Cc. of water, then mixed with 3 Cc. of ammonium carbonate T.S., and 5 Cc. of decinormal silver nitrate V.S., and the whole actively shaken, the filtered liquid, when super-saturated with nitric acid, should not become more than opalescent, nor separate a flocculent precipitate within 3 minutes (absence of more than 3 per cent of chlorine)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Bromine, in vapor, is an irrespirable irritant poison, and, locally applied, is corrosive. An atmosphere impregnated with the fumes occasions excessive secretions and discharges from the throat, nose, and eyes, associated with hoarseness, cough, and difficulty in breathing. Vomiting, intense pain, and diarrhoea, followed by death, are the toxic symptoms. As with iodine and chlorine paralysis of the brain centers is produced; and respiratory paralysis is the direct cause of death. The gastric and intestinal mucous membranes are found corroded and softened. The element, in medicinal doses, is a cerebral sedative, and allays sensory irritability. Faucial anæsthesia is also among its effects. It depresses the sexual functions and somewhat obtunds the sensibility of the genito-urinary passages. Applied to the skin, a weak solution (1 to 8) relieves pain; applied full strength, it is a penetrating cauterant, and may cause gangrenous ulcers. In internal poisoning by bromine the stomach should be washed out and a brisk purgative be administered in alkaline water; in inhalation, alkaline vapors from a steam-atomizer, or better, the cautious inhalation of ammonia, is recommended.

The earliest use of bromine was in those constitutional disorders for which iodine was employed, and in which that drug has now almost entirely superseded bromine. It is, however, still used, in minute doses, in *strumous enlargements* of the lymphatic glandular structures. Here it is given in 1 or 2-grain doses of the 6 x trituration, 3 or 4 times a day. As an inhalation it is sometimes employed in *diphtheria* and *croup* (M x to *aqua flzij*). Bromine is an excellent deodorant and disinfectant. A dilute solution should be employed. During the war of secession it was largely employed as a remedy for *hospital gangrene*. The method of Goldsmith, who introduced this procedure, was to apply the pure bromine upon a lint or cotton swab to the cleansed gangrenous parts, subsequently covering with lint moistened with a weak aqueous solution of bromine, and bandaging the whole with oiled silk. This dressing was followed in a few hours by a poultice,

which separated the eschar, and, by healthy granulation, the wound quickly healed. It has since been employed locally to *diphtheritic membranes*, using equal parts of bromine and potassium bromide ($\frac{1}{4}$ to 3 grains) in water (fl \bar{z} vj). The affected parts are penciled with the solution. The results, however, have been none too satisfactory, and the method is open to serious objections if the larynx be involved, or if broncho-pulmonary disorders exist. *Cancer*, especially of the womb, has been treated with an alcoholic solution of bromine (1 in 2 or 3 parts). *Chancres* and *chancroids* have been destroyed with it, and a sweet-oil solution (M x to fl \bar{z} j) has been employed as a sedative application for *chancroid*, and for the eruption caused by *Rhus Toxicodendron*. Dose, 1 or 2 grains of the 6 x trituration 3 or 4 times a day.

Specific Indications and Uses.—Locally, to hospital gangrene; by inhalation, in croup (10 drops to 1 fluid ounce of hot water).

Bromine Compounds.—**BROMOL.** *Tribromophenol*. Formula: $C_6H_2Br_3OH$. Molecular Weight: 330.06. This compound must not be confounded with *bromal* (see below). When an aqueous solution of carbolic acid (phenol) is acted upon by bromine, bromol results. It forms a white crystalline compound, having an unpleasant, bromine-like odor; to the taste it is sweetish and astringent. It refuses to dissolve in water, but is readily dissolved by alcohol, chloroform, ether, glycerin, and oils. Bromol fuses at $95^\circ C.$ ($203^\circ F.$). Bromol is considered an efficient non-toxic antiseptic. Locally, in glycerin solution (1 in 25), it has been employed in *diphtheria*, in *gangrene*, and upon *tuberculous ulcerations*; internally, as an intestinal antiseptic in *typhus fever* and in *cholera infantum*. The dose is from $\frac{1}{12}$ to $\frac{1}{4}$ grain.

BROMI CHLORIDUM, Chloride of bromine.—Under this name a mixture of chlorine and bromine has been used in medicine. It is probably not, as its name would indicate, a true or definite chemical compound. It is prepared by mixing bromine, 1 part, with cold water, 60 parts, and passing into the mixture a stream of chlorine gas, until the bromine disappears and a dark red solution, having a powerfully irritating odor, results. This volatile liquor is soluble in water, and is intensely caustic. It was used by Landolfi as the chief ingredient of a paste employed for the destruction of *malignant growths*, having been, at one time, quite popular in Europe for the treatment of *cancer*. The remedy soon fell into disrepute.

BROMAL.—Formula: C_2HBr_3O . Molecular Weight: 280.18. Chemically, this compound is analogous to chloral (C_2HCl_3O). It is a colorless, oily fluid, having a distinctive, pungent odor; is a conjunctival irritant, and to the taste is sharp and burning. It is prepared by adding bromine slowly to refrigerated absolute alcohol, and, after several hours' (15 to 24) contact, distilling the mixture, when volatile matter, including bromine, first passes over; subsequently [between 170° to $180^\circ C.$ (341.6° to $356^\circ F.$)] bromal distills and is condensed in an oily condition, congealing at a reduced temperature— $20^\circ C.$ ($-4^\circ F.$). In contact with water large crystals of *bromal hydrate* are produced; with alcohol a crystalline *alcoholate* results. Mere exposure to a moist atmosphere results in the formation of a white mass of crystals of the hydrate of bromal ($C_2HBr_3O \cdot H_2O$). The hydrate melts at $53.5^\circ C.$ ($128.3^\circ F.$); the *alcoholate* at $44^\circ C.$ ($111.2^\circ F.$). Bromoform is produced from bromal and bromal hydrate through the decomposing action of caustic alkalis, the reaction being similar to that by which chloroform is obtained from chloral or its hydrate. The hydrate is soluble in water; the alcoholate but slightly so. Heat decomposes the latter at $100^\circ C.$ ($212^\circ F.$). Bromal may be distilled unchanged, and has a boiling point of 172° to $173^\circ C.$ (341.6° to $343.4^\circ F.$).

Bromal hydrate, the form employed chiefly in medicine, is a powerful irritant. Inflammatory conditions, with cellular infiltration, result from its application to the integument as an ointment. It is a pain-relieving and sleep-producing drug, by some thought to be superior to chloral. It must be employed largely diluted, and, even in dilution, may occasion a sensation of heat in the fauces, diarrhoea, and vomiting. In both warm and cold-blooded animals, according to Stinauer, who investigated it physiologically, it produced moderate sleep, and almost perfect anaesthesia, after previously producing marked restlessness. Dyspnoea and finally death from convulsions ensued, and the ventricles of the heart were found relaxed, or tetanically contracted according to dose—large or small. It has been given in *epilepsy* with varied results. The dose is from 2 to 5 grains, largely diluted.

BROMAMIDE ($C_6H_4Br_2NH.HBr$).—A compound of the anilide group, containing bromine to the extent of about 75 per cent, as calculated from the formula. It occurs in crystalline needles, without taste, odor or color. It is insoluble in water and benzoin, sparingly dissolved by alcohol, but freely soluble in ether, chloroform, and fixed oils. It fuses at $117.2^\circ C.$ ($243^\circ F.$), and heated to $154.4^\circ C.$ ($310^\circ F.$) volatilizes. Owing to its reputed antipyretic properties, it has been used with asserted favorable results in *typhoid fever*, *rheumatic fever*, and *articular rheumatism*, acute and chronic. *Neuralgia*, in its many forms, has been treated with it. It has also been employed with asserted benefit in *nephritic dropsies*. The dose for adults, from 5 to 10 grains; for children, 1 to 5 grains; preferably in capsule, water, or emulsion.

BROMOFORM, Tribromomethane.—Formula: $CHBr_3$. Molecular Weight: 252.25. This liquid is the analogue of chloroform. It is produced when bromine acts upon alcohol in contact with alkaline earths or the caustic alkalis. It is largely made by saturating a solution of calcium hydroxide with bromine, adding alcohol, and distilling the mixture. According to Denigès' method, by which nearly all of the commercial article is now produced, sodium hypobromite is made to act upon acetone, as follows: To a solution of caustic soda bromine is

added, the result being sodium bromide and sodium hypobromite. The mixture is allowed to come into contact with acetone; reaction ensues, resulting in the formation of bromoform and sodium acetate, principally. Bromoform is a sweet, limpid, colorless liquid, emitting an aromatic fragrance. It is dissolved to a slight extent by water, but freely by alcohol and ether. Its density at 0° C. (32° F.) is 2.83. It boils at 147° to 151° C. (296.6° to 308.8° F.) and becomes solid at 2.5° C. (36° F.). Sunlight decomposes bromoform. In administering this drug only that which is colorless and free from acids should be employed. Bromoform was suggested as a pleasant anæsthetic in 1849. Van Horoch, in 1883, investigated and used it as an anæsthetic on man. Its anæsthetic properties are very similar to those of chloroform, though it is slower in action, and, unlike the latter, produces no pre-narcotic excitement. The Schneiderian and conjunctival membranes are sometimes irritated by it. Collapse, coma, and cyanotic countenance are the effects of its toxic action, and bromine is eliminated by the urine. Bromoform is antiseptic, analgesic, and antispasmodic. It is for its action in *whooping-cough* that it is most valued. Though not perfectly miscible with water, it may be prescribed in that liquid; or, for children especially, syrup of acacia, or alcohol, may be employed as a vehicle. The dose ranges from 1 to 5 drops, 3 times a day.

BRYONIA (U. S. P.)—BRYONIA.

The root of *Bryonia dioica*, Jacquin (*Bryonia alba*, Hudson), and *Bryonia alba*, Linné.

Nat. Ord.—Cucurbitaceæ.

COMMON NAMES: *Bryony*, *Snakeweed*, *Devil's turnip*, *Bastard turnip*, *Parasnip turnip*.

ILLUSTRATION: Woodville's *Med. Bot.*, Plate 187.

Botanical Source.—The species used in medicine are *Bryonia dioica* and *Bryonia alba*. The genus to which they belong is a family of herbaceous vines, climbing by means of tendrils. The species, of which there are about 50, are found in most parts of the Old World. They are distinguished from the allied plants of the natural order Cucurbitaceæ, by having the flowers monœcious, or occasionally diœcious, the 5 stamens united into 3 bundles, and the fruit globular and berry-like.

Bryonia dioica belongs to the section of the genus *Bryonia*, with palmately lobed leaves. It is common among the hedges and in the borders of woods in Europe, especially in the calcareous soil of some parts of England, where it is quite ornamental. The stem, which is a rough annual, climbs to the height of several feet above hedges and undershrubs; the leaves are cordate and 5-lobed, the terminal lobe being longer than the others, and dissimilar. The flowers are of a light, greenish-white color, with darker green veins; they are perfectly diœcious in the young plants, although both sexes are often found on older individuals. The fruit is a bright scarlet berry (*red bryonia*), with several flat seeds.

Bryonia alba is a closely related plant, found in Central Europe, Sweden, and Denmark. It has white flowers, regularly lobed leaves, and black berries (*Black bryonia*). These two species of *bryonia* must not be confounded with the black bryony (*Tamus communis*), a European plant of the natural order Dioscoreaceæ.

History and Description.—*Bryonia* has been used in medicine throughout sections of Europe for a great many years, and occupied a conspicuous place in the *London Dispensatory*, published in 1653. It is vulgarly known as *snakeweed*, *devil's turnip*, *parasnip turnip*, and *bastard turnip*. The root, the part employed, is from 2 to 4 inches in diameter, and about 2 feet in length, although occasionally larger. It is fleshy, and when wounded, yields a milky juice. Internally it resembles the root of *Phytolacca decandra*, maintaining the similarity when sliced and dried.

Fig. 50.

Bryonia dioica.

As found in our market, bryonia is in slices, often worm-eaten, or even decayed, and totally unfit for use. It is said that the purgative principle (*Bryonin*), is stable, but, undoubtedly, even though this be the case, it can not withstand the attacks of time and the ravages of insects, for tinctures prepared from inferior specimens will not give satisfaction. The Pharmacopœia describes the drug from both species as follows: "In transverse sections about 5 Cm. (2 inches) in diameter, the bark gray-brown, rough, thin, the central portion whitish or grayish, with numerous small, projecting wood-bundles arranged in circles and radiating lines; fracture short; inodorous; taste disagreeably bitter"—(*U. S. P.*).

Chemical Composition.—In 1858, G. F. Walz published an article upon the chemical composition of *Bryonia alba* (*Archiv. der Pharm.*, cxlvi), the result being the identification of two white, crystallizable bodies, *bryonin* and *bryonitin*. The latter substance, however, was, in 1862, admitted by Walz not to be an individual body, but merely a mixture of a crystalline, fatty acid, and some saponifiable fat (*Amer. Jour. Pharm.*, 1862). To obtain *bryonin* from the root, an alcoholic extract is made of the latter, and the resulting product, after evaporation, is treated with water. After extraction of the aqueous extract with ether, *bryonin*, with impurities, remains in the residuum, and may be obtained by dissolving the residuum in water, precipitating the coloring matter with acetate of lead, the excess of which must be removed with sulphide of hydrogen; after filtration, neutralize the filtrate with carbonate of sodium; then precipitate with tannic acid, dissolve the precipitate in alcohol, digest with calcium hydroxide, filter, digest with animal charcoal, again filter, and evaporate. *Bryonin* is a colorless powder, very bitter, soluble in water and alcohol, and insoluble in ether and in chloroform; when boiled with diluted sulphuric acid it assumes a bluish tint, splits into sugar and two bodies named by Walz, *bryoretin* (soluble in ether), and *hydrobryotin* (insoluble in ether). Walz's analysis would point, for *bryonin*, to the formula $C_{20}H_{32}O_{10}$, while Masson, in 1893, arrived at the formula $C_{20}H_{32}O_8$. Starch, sugar, gum, wax, fatty constituents, albumen, cellulose, and salts, are also present in the root.

Action, Medical Uses, and Dosage.—The fresh root of bryonia is extremely irritating, occasioning blisters when bruised and kept in contact with the skin, and causing serious gastro-intestinal inflammation when taken internally. A profuse and uncontrollable diarrhœa, vomiting, vertigo, reduction of temperature, dilatation of the pupils, cold perspiration, extremely small pulse, colic, collapse, and death have resulted from its use. Its influence on the nervous system is marked. A similar result follows the administration of large doses of the dried root. An infusion of galls is said to antidote it. This root appears to have been well known to the ancients, and was used in various maladies. It has likewise been employed in more recent times in *convulsions* due to the presence of worms in the intestines, as a cathartic in *dropsy*, and in cases of *chronic inflammations*, attended with glandular enlargements, or serous effusions. It is chiefly used at the present day in small doses, as a remedy in *acute and chronic serous maladies*, in *glandular enlargements*, in *scarlatina* to lessen the tendency to aural complications that may terminate in otorrhœa and deafness, in *chronic orchitis*, in *chronic rheumatic affections*, *pleuritic* and *pulmonic disorders*, *fevers*, etc., and to overcome *constipation* and regulate the bowels.

The indications for bryonia, according to Prof. Scudder, are "a hard, vibratile pulse, flushed right cheek, frontal pain extending to the basilar region, and irritative cough." Perhaps no remedy in the whole range of respiratory therapeutics is more valuable than this one, and much of the success of Eclectic physicians in the treatment of lung diseases is the result of the frequent use of specific bryonia. It is the remedy for the sharp, cutting, and lancinating pain with harsh cough. It is equally valuable when the pain is tensive and tearing, especially when aggravated by motion; the parts feel stiff, sore, or bruised, and there is a large quantity of mucus within the bronchioles, as evidenced by the loud mucous rales. When the pulse is hard, frequent, and vibratile, and the temperature is elevated, bryonia is indicated. A prominent indication is the flushed right cheek just above the malar bone. It acts best in small doses. It frees the circulation, overcomes capillary obstruction, lowers temperature, and controls pain. It is the remedy for *inflammation of serous tissues*, and is equally valuable in *peritonitis* and in

synovial inflammations. It lessens nervous excitation and erethism, and promotes secretion and excretion. In *rheumatic conditions of the chest* and in *pleurodynia*, it is valuable, especially if the pain be sharp, and is aggravated by motion. Its best results are observed in *pleurisy*. In simple pleuritis from cold aconite alone is sufficient; but that form of pleurisy which is insidious and complicated, is best treated with bryonia, and in the second stage it hastens the removal of effused material. In the so-called "*bilious*" *pleurisy*, with jaundice and a burning sensation in the lungs, and tenacious mucous expectoration, it proves an excellent drug. In *pleuro-pneumonia* it may be given for its absorptive qualities. *Bronchitis*, with frothy, blood-streaked expectoration; *pneumonia*, with sharp pleuritic pain, or with harsh, harassing cough; and in *cough* aggravated or excited by talking, walking, or tickling in the throat, or by vomiting, it is always indicated. It is beneficial in *typhoid pneumonia*, but should be associated with baptisia. It is valuable in *phthisis* to control pain, lessen temperature, and to allay the troublesome cough. Probably no remedy, excepting gelsemium, was so frequently indicated to control cough and pain in the recent epidemics of "*la grippe*." In nearly all cases in which bryonia is employed it should be associated with aconite, veratrum, lobelia, or gelsemium, as indicated. As a remedy for *cough*, independent of bronchopulmonary complications, it is valuable where the trouble originates in the larynx and trachea, especially that painful cough seemingly located between the suprasternal notch and the bifurcation of the trachea. Such a cough is irritative, and generally due to a nervous erethism, which is controlled by bryonia. The cough is dry, rasping, hacking, or explosive, and always attended with more or less tense or sharp pains. But little, if any, secretion is present, unless it be a small quantity of white or brown, blood-streaked or clotted, frothy mucus. Tickling, irritative cough, aggravated by swallowing food, talking, or upon entering a warm room—the kind of cough produced by cold—is always benefited by bryonia. The bryonia condition is one of debility, and the patient perspires readily. It is a remedy for *fevers*, and will often control them when the special sedatives fail. Chilliness, with a sensation of tension, and that form of cutaneous weakness in which one easily sweats, upon movement, are the conditions for it. Add to this the peculiar bryonia pain, given above, and deepened color of mucous tissues, and full veins, evidencing capillary obstruction, frontal headache, dry tongue, and tendency to delirium—and the bryonia case is complete.

"Aggravated by motion" has long been a phrase applied to bryonia cases, and so we find in these cases a lethargy induced more by a desire to remain quiet than one of dullness, as is noticeable when belladonna is required. The patient is languid, torpid, tired, and has little inclination to go about. A general deficiency of nervous balance is observable, and every effort tends to induce perspiration. With this may or may not be associated the bryonia headache, pain from the frontal region to the occipital base; thinking is an effort, and the patient is irritable if disturbed. Temperature is slightly increased, and the tissues contracted. When any special organ is affected, extreme tenderness and soreness is experienced upon pressure. Thus in *hepatic disorders* with jaundice, high-colored urine, and developing pain upon pressure, it is an excellent drug. Stitching, sticking, or cutting pains about the liver, as if the serous capsule were involved, also indicates bryonia. In *acute rheumatism*, especially where the joints are swollen and feel stiff, it is direct in its action, and is equally valuable in chronic cases; painful and stiff *rheumatism of the spine* in children, *rheumatic headache*, sharp, temporal pain, *frontal headache*, *hemicrania*, with tender scalp, and sharp, tearing pains, made worse by motion, are all conditions for this drug. According to Prof. Locke, it is an absolute specific in *rheumatic swelling of the finger joints*. It is a remedy for *ovarian* and *menstrual wrongs*, with soreness on pressure. *Acute mammitis* is usually controlled by phytolacca, but when very painful and with elevated temperature, and the mammary glands are swollen, tender, and knotted, bryonia and aconite should be associated with the former.

Partial deafness from cold, or from scarlet fever with swollen glands; *chronic orchitis*, *rheumatic paralysis*, *scrofulous conditions of the ears and eyes*, and *scrofulous ulcers* and *white swelling*, with stinging, burning pain, are relieved by bryonia (Locke). Tensive pains in the ear in children call for bryonia. Prompt results were obtained from bryonia in an inveterate case of *facial neuralgia* of 6 years

standing, by Prof. W. B. Scudder (*Ec. Med. Jour.*, p. 144, 1894). The patient had a weak heart, and cold hands and feet, a countenance like one accustomed to morphine, and fugitive, lightning-like pain, involving the left side of the head and left eye, coming on at intervals of a half minute, and lasting a few seconds. So severe was the pain that the patient had to grasp a chair to support himself during the paroxysm. A peculiarity of the case was a hyperæsthetic spot upon the upper lip and gum the size of a silver dollar, so sensitive that even the contact of a soft cloth could not be borne. Bryonia is the remedy for *rheumatic iritis*, with aching soreness upon movement of the eyeball; also in non-edematous puffiness of the upper eyelid.

Bryonia seems to be a valuable heart tonic in weak and delicate individuals, who, by overwork and nervous excitation bring on a depressed and irregular heart-action (*heart-strain*); and even in organic heart troubles when exposure and rheumatic twinges bring on the cardiac paroxysm, bryonia, with rest in bed, is asserted to powerfully and rapidly influence the condition for good.

In *peritonitis* the pain requiring bryonia is of the character of colic, but is marked by unusual tenderness and tension. Bryonia is valuable in *pericarditis* tending to *hydropericardium*, and in *brain disorders* with serous exudation.

Bryonia should not be forgotten in ordinary *indigestion*, where the food lies heavily, as if a stone were in the stomach. Ordinary *jaundice* is often cured with it, and in *typhoid fever*, as soon as pulmonic complications ensue, the patient should be put upon bryonia. Some cases of *infantile constipation* are said to be benefited by bryonia, especially such as are due to gastric disorders arising from difficult digestion of cow's milk. It does not, however, benefit all cases. Scudder calls especial attention to its use in the abdominal tenderness and pain in *typho-malarial fever*, and *zymotic diseases*, and associated with ipecac or euphorbia in *cholera infantum*, with abdominal tension and tenderness, or articular pain and swelling (*Dis. of Child.*, p. 31).

Bryonia should never be given in large doses. The usual prescription reads Specific bryonia, gtt. v to x, aqua fl̄iv. Dose, a teaspoonful every 1 to 3 hours, as indicated. Some, however, and Prof. Locke particularly, prefer the first decimal dilution of specific bryonia, of which from 5 to 20 drops should be added to 4 ounces of water, and the dose of which is 1 teaspoonful. Tincture of bryonia may be given in doses of a fraction of a drop to 1 drop.

Specific Indications and Uses.—Sharp, cutting, lancinating, or tearing pain, from serous inflammation; pain in serous cavities, with muscular tension and tenderness on pressure; tensive, sharp, tearing pain, with a sore feeling in any part of the body as if bruised, and always *aggravated by motion*; dry, sensitive skin; hard, moderately full, or hard, wiry, vibratile pulse, tensive rheumatic pain, made worse by motion; headache on right side, with flushed right cheek above malar bone (a prominent indication); frontal pain extending alongside of head to basilar region; hyperæsthesia of face or scalp; head so sore that one can not bear to be touched; pleuritic pain; neuralgic pain with hyperæsthesia; irritative, hacking, rasping, or explosive cough, with soreness or bruised feeling of parts, and with laryngeal and suprasternal soreness and tenderness; abdominal pain with tenderness; ocular tenderness, increased by movement; tensive earache; articular and synovial pain, swelling, and tenderness; bowels constipated and urine scanty; burning in eyes and nose, with acrid nasal flow; apathy or lethargy short of dullness, from disinclination to move on account of aggravation of condition; tired, weary feeling, too tired to think; disposition to perspire on the slightest movement.

Related Species and Drugs.—**TAYUYA ROOT.** This Brazilian root is said to be that of the *Trianosperma ficifolia*. It is proposed as a remedy for *scrofula*, *tertiary*, *sypthika*, *dropsy*, *paralysis*, and *stubborn skin diseases*. Dose of tincture, 5 to 15 drops.

Bryonia africana, Thunberg. South Africa. Used like bryonia.

Bryonia americana, Lamarck. West Indies. Employed for same purposes as bryonia.

Corallocarpus epigæa, Hooker filius (*Bryonia epigæa*, Rottl.). A native of Java, and considerably employed by the natives of India, where it is found also, as a valuable remedy for *snakebites*, *dysentery*, and *sypthitic disorders*. The tuber is somewhat turnip-shaped, large, often weighing 5 or 6 pounds, has a subacid, bitter taste and is mucilaginous. The viscid juice which exudes upon cutting the tuber hardens into an opalescent gum. The root is cathartic and anthelmintic. M. Jules Lepine, of Pondicherry, found in it a yellow bitter body refusing

to crystallize, and thought to be probably identical with bryonin (Dymock, *Mat. Med. of Western India*). *Bryonia laciniosa*, Linné, also found in India, is aperient and tonic. The whole plant, in fruit, is used.

BUCHU (U. S. P.)—BUCHU.

"The leaves of *Barosma betulina* (Thunberg), Bartling et Wendland, and *Barosma crenulata* (Linné), Hooker"—(U. S. P.).

Nat. Ord.—Rutaceæ.

COMMON NAME: *Buchu*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 45, 46.

The synonymy of the official plants yielding buchu is somewhat uncertain. The following are generally recognized:

I. *Barosma betulina*, Bartling (*Diosma crenata*, De Candolle and others; *Diosma betulina*, Thunberg).

II. *Barosma crenulata*, Hooker (*Barosma crenata*, Kunze; *Diosma crenulata*, Linné; *Diosma crenata*, Linné; *Diosma odorata*, De Candolle).

Botanical Source.—The official buchu leaves are derived from plants which are chiefly differentiated from each other by their leaves. They are both slender, smooth, perennial shrubs, having twiggy, somewhat angular branches, of a purplish-brown color, and reach a height of from 2 to 3 feet. The flowers are white or pinkish. The leaves are opposite, or nearly so, and are almost sessile, or, at best, having but a very short petiole. Five upright carpels, each containing a single oblong, shining black seed, comprise the fruit. The leaves are conspicuously marked with oil glands appearing as pellucid spots. The leaves of other species also appear in commerce, conspicuous among which are those of the *Barosma serratifolia*, Willdenow.

History.—The plants yielding buchu are indigenous to Southern Africa, occupying a limited extent of territory. According to Burchell they are odoriferous, and are, when powdered, used by the Hottentots under the name of *Bookoo* or *Buku*, for anointing their bodies. They likewise prepare a buchu brandy by distilling the leaves with wine, and which they employ as an efficient remedy in all affections of the stomach, bowels, and bladder; they also apply a decoction of the leaves to wounds. Buchu is said to have been introduced into medicine by a London drug firm (Reece & Co., in 1821), to whom a supply had been sent by Cape Colonists, who learned its uses from the Hottentots (*Pharmacographia*). Buchu leaves have a strong odor, resembling somewhat that of pennyroyal, and a corresponding taste. When held up to the light translucent dots may be observed, owing to the fact that the under surface of the leaves is beset with scattered glandular oil-points. If buchu leaves be preserved with ordinary care, their odor will remain for some years. The long variety of buchu is occasionally adulterated with leaves of *Empleurum serrulatum*, Aiton (*Rutaceæ*), a shrub growing in the same locality with buchu. They have a different odor from buchu, a bitter taste, are narrower than buchu leaves, and the oil-gland at the apex, present in *B. serratifolia*, is absent. Moreover, the adulterant has leaves with an acute apex, while those of long buchu are truncate. The leaves of another species of the same order, the *B. Eckloniana*, Berg, has also been imported with true buchu. They are markedly crenate, have a rounded base, and are grown on pubescent twigs (*Pharmacographia*).

Description.—Buchu is described in the U. S. P. as follows: "About 15 Mm. ($\frac{1}{2}$ inch) long, roundish-obovate, with a rather wedge-shaped base, or varying between oval and obovate, obtuse, crenate or serrate, with a gland at the base of each tooth, dull yellowish-green, thickish, pellucid-punctate; odor and taste strongly aromatic, somewhat mint-like, pungent and bitterish"—(U. S. P.). The two official species of buchu constitute the *short (round) buchu* of commerce. The leaves of the *B. betulina* compose the greater amount of this grade. They range from $\frac{1}{4}$ to $\frac{3}{4}$ inch in length, and possess more rigidity than the second species. These leaves are obovate and wedge-shaped toward the petiole, and usually have

Buchu leaves.

the apex curved backward. The margins are bordered with sharp serratures, an oil-gland being set at the base of each serrature. This variety varies somewhat in size and shape. The second species, *B. crenulata*, has longer leaves (from $\frac{3}{4}$ to $1\frac{1}{2}$ inch), which have a crenately serrulate margin, each indenture having an oil-gland situated at the bottom of it. They may be oval, oblong, or obovate, and are narrower than the preceding variety. The longer and large leaves constitute the commercial *intermediate buchu*. This species presents but little variation in the size and shape of its leaves. The *long buchu* of commerce is that derived from the *Barosma serratifolia*, Willdenow (*Diosma serratifolia*, Curtis), official in the U. S. P., of 1880. These leaves differ considerably from the preceding, having a lance-linear form, irregularly narrowing towards each extremity, and have a truncate apex furnished with an oil-gland. They range from 1 to $1\frac{1}{2}$ inch in length, and have a sharply serrulate margin, each serrature containing an oil-cell.

Chemical Composition.—Buchu leaves have been analyzed by Brandes and Cadet de Gassicourt, and later by Flückiger, Hanbury, and P. W. Bedford. Gassicourt found them to contain volatile oil (0.665 per cent), gum, extractive, chlorophyll, resin, lignin, etc. The leaves also contain mucilage. Their virtues are chiefly due to the volatile oil and extractive, which they yield to alcohol, or water. The oil has a powerful penetrating odor, somewhat like that of peppermint. Different amounts of the volatile oil were obtained by the above-named investigators, that derived from the long buchu being of lesser quantity than that from the short leaves. According to Schimmel & Co. (*Semi-Annual Report*, Oct., 1898), the percentage yield from *B. betulina* is 2 per cent, and from *B. serratifolia* 1 per cent. On subjecting this volatile oil to a low temperature, a stearopten, known as *diosphenol* ($C_{14}H_{22}O_3$), or *barosma camphor* separates, which may be recrystallized from alcohol in needles. When pure they are colorless, and, according to Flückiger, have a nearly pure peppermint odor. They dissolve freely in carbon disulphide. *Barosma camphor* is present only in a small amount in the *B. serratifolia*, while the *B. betulina* is very rich in diosphenol. The specific gravity of the oil from the last variety (*B. betulina*) is 0.944, at 15° C. (59° F.), while that from the *B. serratifolia*, after elimination of diosphenol, which separates at ordinary temperature, is 0.969, at 15° C. (59° F.) (Schimmel's *Report*). Diosphenol can not be distilled without decomposition. Both Brand and Landerer had observed bodies to which they gave the name *diosmin*. That of the former was a bitterish body, while that of the latter was probably the stearopten diosphenol, as he observed it in a tincture of buchu, which had been made for some length of time. Prof. E. F. Wayne obtained salicylic acid by distilling the leaves. Others have failed to find it. The ash of buchu leaves contains considerable manganese. *Barosma crenulata* was examined by Spica, who found an oil differing somewhat from that of the other observers, and the diosphenol obtained he regarded as an oxycamphor. From the greenish-yellow mint-like oil he obtained a body, the odor of which resembled thymol. To this body he applied the name *dioacamphor*. From the residue after the extraction of the oil he obtained, by means of alcohol, a substance to which he gave the name *diosmin* (*Ph. J. Tr.*, 1885).

Action, Medical Uses, and Dosage.—Buchu is an aromatic stimulant and tonic. It promotes the appetite, relieves nausea and flatulence, and acts as a diuretic and diaphoretic. In favoring the urinary secretion it augments both the solid and watery constituents. On the other hand, when the kidneys are excessively active, their action is restrained by buchu. It is principally used in chronic diseases of the urino-genital organs, as in cases of *chronic inflammation of the mucous membrane of the bladder, irritable conditions of the urethra*, in urinary discharges with increased deposit of uric acid, and in incontinence connected with diseased prostate. Profuse muco, or muco-purulent discharges, with vesico-renal irritation, point to its use. It is a remedy where irritation depends upon altered secretions from the urethral glands. Acid urine, with continual desire to urinate and when but little relief is experienced from the effort, calls for buchu. *Catarrh of the bladder*, from the extension of gonorrhoea, from irritant injections, or due to gleet, is relieved by it. For this use, as well as for long-standing *cystic irritability*, the patient having difficulty in restraining his urine, administer the following: R Specific barosma, ājīiiss ; tinct. chloride of iron, ājss . Mix. Sig. A teaspoonful 4 times a day in a wine-glassful of infusion of hops or in sweetened

water. Upon the prostate gland it is said to resemble thuja in its action, though it is less powerful than the latter. Some have found it beneficial in *dyspeptic, cutaneous, and rheumatic affections*. I do not, however, think it equal to many of our indigenous remedies, which are sadly neglected by the profession, in their eagerness for something at a distance from home. Were our native plants more closely investigated, there would be but little use for foreign, and consequently expensive agents (Prof. King). Under favorable circumstances a warm infusion of buchu leaves will cause diaphoresis. Dose of the powder, from 20 to 30 grains, 2 or 3 times a day; of the infusion, 2 to 4 fluid ounces, 3 or 4 times a day; of the tincture, 1 to 2 fluid drachms; specific barosma, 10 to 60 drops, well diluted, from 3 to 6 times a day.

Specific Indications and Uses.—Abnormally acid urine, with constant desire to urinate, with but little relief from micturition; vesico-renal irritation; copious mucous, or muco-purulent discharges; cystorrhoea.

BUXUS.—BOX.

The leaves of the *Buxus sempervirens*, Linné.

Nat. Ord.—Euphorbiaceæ.

COMMON NAME: Box.

Botanical Source.—*Buxus sempervirens* is a small, dense-leaved, hard-wooded, evergreen tree. Its leaves are ovate, opposite, of a deep, shining green, becoming red in the autumn, quite smooth and entire, with the cuticle of the underside readily stripping off; the petioles and young branches are slightly downy; the flowers aggregate, axillary, and pale-yellow; the capsule is globular, 3-horned, trilocular, 6-seeded, and bursts elastically; the seeds are parallel, oblong, slightly compressed, and externally rounded (L.).

History.—This is an exotic, though generally well-known plant, growing on dry, chalky hills in Europe, and the west of Asia. One variety of it, the *B. suffruticosa* (Dwarf-box), with obovate leaves, and a stem scarcely woody, and which is much esteemed for borders along the walks of gardens, possesses similar medicinal virtues. It is of very slow growth, a tree 8 feet high must be 100 years old. The wood is yellow, very hard, and much used by wood-engravers for wood-cuts; also for other purposes. The leaves, which are the parts used, are bitter and nauseous, and impart their properties to water or alcohol. The bark has been used to some extent to adulterate pomegranate bark.

Chemical Composition.—The bark of box-tree was found by M. Fauré to contain among chlorophyll, wax, resin, gum, ash, etc., a bitter alkaloid, which he named *buxine*. This alkaloid was obtained by exhausting the powdered bark with alcohol, evaporating the liquid, dissolving the residue in water, and treating the solution with ammonia. The precipitate thus obtained was digested in alcohol, which, being evaporated, left a dark-brown translucent mass, which is the *buxine*. It is bitter, causes sneezing, is insoluble in water, slightly so in ether, readily so in alcohol, and is difficult to obtain white, even when treated with animal charcoal. It colors red litmus blue, and forms neutral salts with acids. Nitric acid added to the sulphate of *buxine*, removes a resinous matter and leaves the sulphate of *buxine* pure; from this salt, pure *buxine* may be obtained in crystals.

Buxine was shown by Walz (1860) to be apparently the same body as *bebeerine* (from *Nectandra Rodiei*, Schomburgk, or *bebeeru* bark), which observation was confirmed by Prof. Flückiger (1869), who has further shown that both *bebeerine* and *buxine* do not differ essentially from *pelosine*, an alkaloid derived from both *Cissampelos Pareira*, Linné (*Common False Pareira brava*), and *Chondodendron tomentosum*, Ruiz et Pavon (*True Pareira brava*). A second alkaloid, discovered by Pavia, and investigated by Rotondi and Pavesi, received from the latter investigator the name *parabuxine* ($C_{20}H_{25}N_2O$). Still another alkaloid, *parabuxinidine*, in the form of prisms, without color, and capable of producing a deep-red hue with turmeric paper, has been announced by Barbaglia (*A. J. P.*, 1885). It dissolves in alcohol and ether, but not in water. An alcoholic solution of oxalic acid yields a heavy crystalline precipitate with solutions of the alkaloid. Tannin is said to be present in the leaves, as well as a fetid volatile oil.

Action, Medical Uses, and Dosage.—Cathartic, sudorific, alterative, and anthelmintic. It may be used, in syrup or extract, in all diseases where an alterative is required. In doses of 10 or 20 grains of the powdered leaves, it proves an excellent vermifuge. The dose of a strong decoction, or syrup, is from $\frac{1}{2}$ fluid ounce to 1 fluid ounce, 3 or 4 times a day. And in combination with the *stillingia* and *corydalis*, in the form of a syrup, it forms a very useful tonic and alterative in *syphilis*. Reputed to possess antispasmodic virtues, and to have been beneficially used in *epilepsy*, *chorea*, *hysteria*, etc., but requires further corroboration. Chips of the wood are said to have the same properties, and have been prescribed in *secondary syphilitic diseases*, and *chronic rheumatism*. A fetid empyreumatic oil, *oleum buxi*, was formerly prepared, but the use of which has become superseded by the preparations of *guaiacum*; it has, however, been successfully used in *toothache*. Camels who eat the leaves are said to become poisoned.

CACTUS.—CACTUS.

The fresh (green) stems and flowers of *Cactus grandiflorus*, Linné (*Cereus grandiflorus*, Miller and De Candolle).

COMMON NAMES: *Night-blooming cereus*, *Large-flowered cactus*, *Sweet-scented cactus*, *Vanilla cactus*.

Botanical Source.—*Cactus grandiflorus* is a creeping, rooting, fleshy shrub, having cylindrical or prismatic stems, with about 5 or 6 not very prominent angles, branching, and armed with clusters of small spines, arranged in radiated forms. The flowers are terminal and lateral, from the clusters of spines, very large, 8 to 12 inches in diameter, expanding at night, enduring for a few hours, and exhaling a vanilla-like odor. The petals are white, spreading, and shorter than the sepals; the sepals are linear-lanceolate, brown without, and yellow within. The fruit, or berry, is ovate, covered with scaly tubercles, fleshy, and of an orange, or fine reddish color. The seeds are very small and acid.

Fig. 52.

Cactus grandiflorus.

History.—*Cactus grandiflorus* (*Cereus grandiflorus* of De Candolle), *Night-blooming cereus*, also known by the names, *Vanilla cactus*, *Sweet-scented cactus*, *Large-flowered cactus*, is indigenous to Mexico and the West Indies, and also grows in Naples, where it blooms in July. In Mexico it was, at one time, a popular remedy for various diseases, as irritation

of the kidneys and bladder, intermittent fever, difficulty in breathing, cough, etc. It is rarely met with in the higher temperate latitudes, where it is of difficult culture. *Night-blooming cereus* is a handsome and very showy shrub. Its blossoms commence expanding about 6 or 7 o'clock in the evening, and are fully blown about midnight; but about 3 or 4 o'clock in the morning, they are quite decayed; during its continuance, however, there is scarcely any known flower of greater beauty. The perianth, when open, measures nearly a foot in diameter; the outer leaflets are of a dark-brown color, the inner ones are of a splendid yellow, gradually shaded, toward the center of the flower, into a pure and brilliant white. These flowers are delightfully fragrant, and fill the air with odors to a considerable distance. When the flower has withered, the ovary enlarges and becomes pulpy, and forms an acid juicy fruit, having some resemblance to a gooseberry. The plant was introduced to the medical profession by Dr. Scheele, of Germany; but little attention, however, was given to it, until Dr. R. Rubini, a Homœopathic physician of Naples, brought it into especial notice as a remedy in heart diseases. The parts of the plant used in medicine are the flowers and young and tender stems, which should be gathered in July, and at once made

into a tincture. The plant is mucilaginous, and when beaten in a mortar forms a viscid magma. No satisfactory analysis has been made of this plant, nor has it been satisfactorily ascertained whether the plant growing in its natural latitudes has any more powerful action than that cultivated in higher temperate latitudes.

Action, Medical Uses, and Dosage.—Cactus impresses the sympathetic nervous system, and is especially active in its power over the cardiac plexus. In sufficiently large doses it acts as an intense irritant to the cardiac ganglia, producing thereby irritability, hyperæsthesia, arrhythmia, spasm and neuralgia of the heart, and even carditis and pericarditis. According to E. M. Hale, M. D., it acts upon the circular cardiac fibers, whereas digitalis acts upon all the muscular fibers of the heart. Like the latter, as a secondary effect of over-stimulation, it may induce heart-failure. The tincture, in large doses, produces gastric irritation, and also affects the brain, causing confusion of mind, hallucination, and slight delirium. In excessive doses, a quickened pulse, constrictive headache, or constrictive sensation in the chest, cardiac pain with palpitation, vertigo, dimness of sight, over-sensitiveness to noises, and a disposition to be sad or to imagine evil, are among its many nervous manifestations. Melancholia often follows such action. It is generally conceded, however, that the mental, cerebral, gastric, and other effects are secondary to and dependent largely upon the primary effects of the drug upon the heart.

In medicinal doses, night-blooming cereus diminishes the frequency of the pulse, and increases the renal secretions, and is, therefore, sedative and diuretic. According to Prof. Scudder (*Spec. Med.*), it neither increases nor depresses innervation; that it is neither stimulant nor sedative. Prof. Locke, on the other hand, believes it sedative, but not depressant (*Syllab. of Mat. Med.*). In such doses it does not appear to weaken the nervous system in the least. The special field for cactus is *diseases of the heart*, in which it exerts a very decided action, palliating or removing the symptoms, and frequently giving prompt relief. This influence upon the heart is manifested when the disorder is functional; organic conditions are only benefited in a measure. However, our Allopathic antagonists, who are generally skeptical regarding the virtues of plants which do not possess unusually powerful properties, consider cactus as a valuable agent in *mitral regurgitation*, due to valvular lesions. In our school, however, it is recognized chiefly as a *functional* remedy, and one of the best of cardiac tonics. There is no doubt but that the continued use of the drug tends to increase cardiac nutrition and waste, and in this way may benefit cases with structural lesions. The influence of cactus is exerted wholly upon the sympathetic nervous system, through the superior cervical ganglion, expending its force in regulating the action of the heart and controlling the cerebral circulation, thus giving increased nutrition to the brain. It is the remedy for almost all *functional cardiac irregularities*, as *palpitation*, *pain*, *cardiac dyspnoea*, *intermission in rhythm*, etc. Even in structural heart-wrongs, the majority of unpleasant symptoms are due to disordered innervation, and this condition is corrected by cactus. It does not seem to make any difference whether the heart-action be feeble, violent, or irregular, provided it be due to lack of innervation, associated with mental depression, or in excitable or nervous individuals, the remedy relieves, because its tendency is to promote normal rhythmic action of the cardiac muscle. In *spasm of the heart-muscle*, and in *cardiac pain* of a constrictive character, as if the organ were held with a strong band, it is the most prompt of all cardiac remedies. It is a good remedy in the heart troubles produced by tobacco. In *palpitation*, *angina pectoris*, *cardiac neuralgia*, *rheumatism*, or *hypertrophy*, *valvular disease*, etc., it is of much benefit, often giving great relief, even in incurable cases. It has been likewise found serviceable in some cases of *dropsy*, and in tendency to, or in incipient *apoplexy*. *Pulmonary hemorrhage*, particularly that accompanying phthisis and in advanced *interstitial pneumonia*, prompt results may be expected from cactus. Its use should be associated with iron in anemic cases, with tonics where great debility exists, with antiscrofulous agents where there is a scrofulous disposition, etc. When associated with cardiac weakness and irregularities, and in so far as they depend upon these conditions, it has likewise been found useful in *cerebral congestion*, *mental derangements*, *rheumatism*, *inflammations of mucous membranes*, *prostatic diseases*, *irritable bladder*, *renal congestion*,

general dropsy, cedematous condition of the limbs, dysmenorrhœa, chronic bronchitis, etc When a vigorous and healthy action of the heart obtains under its use these troubles pass away.

Cactus is recommended in *visual defects* of an asthenopic character, and in *exophthalmic goitre*, due to functional heart disease; *tinnitus aurium*, from the same cause, is benefited by it. These eye and ear disorders are not benefited by it when the cardiac disorder is of an organic nature.

The peculiar state of the nervous system in cardiac diseases, calling for cactus, is quite characteristic. There is a marked mental depression, often amounting to hypochondria and fear of impending death. Associated with these are præcordial weight and oppression and difficult breathing. During the menstrual period and at the menopause, nervous women frequently experience unpleasant cardiac disturbances of a functional character. These are promptly relieved by cactus. For the *nervous menstrual headache*, Prof. Locke recommends: R Specific cactus, grt. x to xxx; aqua, fl̄iv. Mix. Sig. Dose, a teaspoonful 3 or 4 times a day. It has a marked control over the nervous system, somewhat like that of pulsatilla.

The effects of cactus are permanent and not merely temporary. The nutrition of the heart is increased, the contractile power augmented, and the irregular movements regulated.

The dose of tincture of cactus (plant, 3iv to alcohol, 98 per cent, Oj) is from a fraction of a drop to 10 drops; of specific cactus, a fraction of a drop to 5 drops.

Specific Indications and Uses.—Impaired heart-action, whether feeble, violent, or irregular; cardiac disorder, with nervousness, præcordial oppression, anxiety, apprehension of danger, or death; hysteria; tobacco heart; nervous disorders, with heart complications.

Related Species.—Many species of the cactus family have been used for food and medicine; others furnish acid fruits which yield a refreshing juice to thirsty travelers, while the seeds of some species have been roasted and made into bread. The *Opuntias*, growing wild in Texas, are roasted and fed to cattle, and it is recorded that horses and mules will crush with their hoofs various members of the order *Cactaceæ* to obtain the acid juices, of which they are exceedingly fond. The following represent a few of the species which have been employed more or less as a medicine, or for some other economic purpose:

Cactus flagelliformis, Linné (*Cereus flagelliformis*, Miller).—Red or pink flowers; stem-branches spiny, verrucose, 10-angled, slender, weak and prostrate, and many feet long. This plant has an acid juice and wooly fruit. Buchner (1836) found it to contain albumen, mucilage, bimalate of calcium, and acetate of potassium. Its juice is said to possess anthelmintic properties.

Cactus fimbriatus, Lamarck (*Cereus fimbriatus*, De Candolle).—Stock 8 or 10-angled and erect; spines clustered; flowers rose-pink; and fruit red and acid. The juice of the plant is acid.

Cactus paniculatus, Lamarck (*Cereus paniculatus*, De Candolle).—Stock 4-angled; branches spiny and crenated. The whole plant is tree-like, and bears sweetish-acidulous, yellowish fruit (berry).

Opuntia vulgaris, Miller (*Cactus Opuntia*, Linné). *Prickly pear*, *Indian fig*.—Stock prostrate, glaucous, with minute, scale-like leaves, a few spines and numerous bristles. The flowers are large and yellow. The fruit ovoid, almost smooth, slightly bristly, crimson when mature, and edible, having a sweetish, acidulous taste. According to careful analysis by Miss De Graffe (*A. J. P.*, 1896) neither alkaloids, glucosids, nor tannin occur in the fruit, but sugar is present in comparatively large amount. Used as a discutient, and the decoction is mucilaginous. Grows in the West Indies and from Connecticut to Texas, delighting in rocky situations. This species is said to effect the intestinal mucous surfaces and probably the abdominal nerves. *Diarrhœa*, with excessive nausea, is reputed to have been cured by *Opuntia vulgaris*.

Melocactus communis, Link et Otto (*Cactus Melocactus*, Linné).—West Indies. Stock succulent, round-ovate, about a foot high, and from 12 to 18-ribbed, brown clustered spines; stock surmounted by what resembles a spadix, consisting chiefly of dense, woolly tufts, in the summit of which are imbedded the small red blossoms. The bruised stems are employed as a discutient. The red berries of this and other species are said to impart a red color to the urine.

Anhalonium Lewinii, Henning.—Habitat Mexico, where it is known as *Muscale buttons*, and employed for narcotic purposes. Lewin (1888) isolated an alkaloid, *anhalonine* ($C_{12}H_{12}NO_2$). The anhalonium is said to grow on high chalk-cliffs and on almost inaccessible mountain peaks. Anhalonine paralyzes the spinal-cord, and increases reflex action, and may produce tetanic symptoms. Vomiting is induced by small doses of it. The fruit has a somewhat prolonged intoxicant action. Anhalonium is reputed a cardiac tonic, and is said also to be a remedy for all forms of *dyspnœa* (?), and of value in *angina pectoris*, to control the painful paroxysms.

Mammillaria simplex, Haworth (*Cactus mammillaris*, Linné).—Stock ovate-oblong, simple, studded with tubercular mammillæ, having spines, and bearing white flowers and red fruit.

CADMIUM IODIDUM.—CADMIUM IODIDE.

FORMULA: CdI_2 . MOLECULAR WEIGHT: 364.56.

SYNONYMS: *Iodidum cadmicum*, *Cadmium iodatum*.

Preparation.—Cadmium combines readily with iodine, either by heating the two substances together, or by boiling them in water till a solution is obtained. By evaporating this solution the iodide of cadmium crystallizes in 6-sided prisms. It may also be prepared by the double decomposition of 4 parts of iodide of potassium and 3 parts of sulphate of cadmium, and crystallizing from alcohol (absolute). It may further be made by dissolving cadmium in hydriodic acid.

Description.—Cadmium iodide crystals are white, with a silvery-satin or pearly luster resembling fish scales, transparent, permanent in the air, and melt very easily at 315.5°C . (600°F .), forming a liquid of an amber color. Strongly heated, the iodine is driven off. They are soluble in water and alcohol, from which solutions they are precipitated by the alkaline carbonates, furnishing carbonate of cadmium. With starch and chlorine, cadmium iodide yields a blue color, and with sulphide of hydrogen, a yellow precipitate. Its solution in water is of acid reaction. It is extensively employed by photographers.

Action and Medical Uses.—(For action, see *Cadmium*). Iodide of cadmium has been used as a substitute for iodide of lead, in external applications. It is said to produce the same beneficial effects as the latter agent, without any of its deleterious effects. It may be dissolved in glycerin, and must be applied by friction, in order to produce any effect. An ointment composed of 1 part of iodide of cadmium to 8 parts of lard has been found very useful in *chilblains*, some forms of *cutaneous disease*, *chronic inflammatory affections of the joints*, various forms of *nodes*, *scrofulous tumors*, etc.

Cadmium and its Compounds.—CADMIUM. Symbol: Cd. Atomic weight: 111.8. This metallic element was discovered by Stromeyer and Hermann about the year 1818. It usually occurs associated with the oxide of zinc obtained in the manufacture of this metal, from which it is separated as indicated below. It occurs native in Scotland as *greenockite*, a sulphide of cadmium. It resembles zinc in many of its physical and chemical characteristics. It differs, however, from zinc in forming with sulphide of hydrogen a *yellow* precipitate, which, like zinc sulphide, dissolves in diluted acids, but is insoluble in potassium cyanide solution. Cadmium may be obtained by dissolving in diluted hydrochloric or sulphuric acid, the zinc ore containing it, or the oxides resulting from the manufacture of zinc, and then precipitating the cadmium with zinc. It may also be prepared by taking the solutions in acids, and precipitating cadmium sulphide by means of hydrogen sulphide, zinc sulphide remaining in solution. The yellow product is then dissolved in concentrated chlorhydric acid, a precipitate produced by adding carbonate of ammonium in excess, and finally distilling the well-washed and dried precipitate with lampblack. Cadmium has a white color, with a slight bluish-gray tinge, is soft, very malleable, crystallizes in regular octahedrons, is very fusible, melting before it becomes red hot, and at a temperature somewhat higher than the boiling point of mercury. It is volatile, collecting in drops and crystallizing as it cools. Cadmium breaks with a fibrous fracture, and may be rolled out as foil or drawn as wire, and when bent, crepitates like tin. Its density (molten) is 8.546, and (hammered) 8.667. Nitric acid, also hydrochloric and hydriodic acids, readily dissolve it. Its dark-yellow vapor burns with a deep-red flame. Its solutions in acids yield a characteristic yellow precipitate (CdS), with hydrogen (or ammonium) sulphide; insoluble in yellow ammonium sulphide (difference from arsenic). White precipitates are obtained with alkaline hydroxides, phosphates, soluble carbonated alkalies, oxalates, and yellow prussiate of potash. Zinc and copper are apt to be present as impurities. Cadmium salts, which are soluble, are powerful agents, producing vomiting, purging, slow pulsation, slow respiration, vertigo, prostration, insensibility, and painful convulsions. Simpson compared their effects to those of antimony, while Garrod, who introduced the iodide into practice, thought them more nearly related to zinc salts.

CADMIUM SULPHAS, *Sulphate of cadmium*, *Sulphas cadmicus*, *Cadmium sulphuricum* ($3\text{CdSO}_4 + 8\text{H}_2\text{O}$) = 768.64).—This salt may be obtained by dissolving carbonate of cadmium, obtained by first making a solution of cadmium nitrate, and precipitating by the addition of sodium carbonate in diluted sulphuric acid, and evaporating the neutral liquid to crystallization; or, by dissolving 7 parts of cadmium in a mixture of 64 parts of sulphuric acid, 15 parts of water, and a small portion of nitric acid. Evaporate the solution to dryness, dissolve the residuum in distilled water, filter, and evaporate to form crystals. This salt crystallizes in large, transparent, rectangular prisms, similar in appearance to sulphate of zinc. They are very soluble in water, effloresce strongly when exposed to the air, lose their water of crystallization at a low heat without fusing, and at a strong red heat are changed into tabular crystals of subsulphate of cadmium, which are not very soluble in water. Their taste is astringent and metallic. Its aqueous solution has an acid reaction.

The effects of sulphate of cadmium on the system are said to resemble those of sulphate of zinc, but are 10 times more active. Internally $\frac{1}{2}$ grain has produced a copious flow of saliva, nausea, vomiting, and pain. It has been recommended as an irritant and astringent topical application in affections of the eye, specks and opacities of the cornea, etc. As an application in chronic ophthalmia, from $\frac{1}{4}$ grain to 4 grains may be dissolved in a fluid ounce of water; in *dorrhœa* the solution may be made of double the above strength. In specks on the cornea, an ointment has been used, composed of 1 or 2 grains of the sulphate to 80 grains of prepared lard. Cadmium bromide, largely employed in photography, was formerly used in *epilepsy* by Roux, but was abandoned on account of its emetic effects. Two women were poisoned with it, the agent producing severe gastro-intestinal disturbances. Cadmium carbonate has poisoned the operator by inhalation, while he was using it to polish silver.

CAFFEA.—COFFEE.

The seeds of *Coffea arabica*, Linné.

Nat. Ord.—Rubiaceæ.

COMMON NAME: Coffee.

ILLUSTRATIONS: Köhler's *Medicinal-Pflanzen*, Plate 106. Bentley and Trimen, *Med. Plants*, 144.

Botanical Source.—(See *Cultivation and Collection*).

History and Description.—The coffee plant is a native of Arabia Felix and Ethiopia, and is extensively cultivated in Asia and America between the north and south latitudes of 56°. The plant is propagated from the seeds, which sprout in 3 or 4 weeks, and are sufficiently advanced in the course of 12 months for transposition. The fruit appears in about 3 years, and the ripening of the seeds may be known by the dark-red color of the berries, when they must be gathered, else they will fall spontaneously. The fleshy part is removed from the seeds by certain apparatus, and their thin covering is detached after drying. There are many varieties of coffee, the characters of which depend upon the soil, the locality and the method of cultivation. The origin of its employment is still surrounded with many obscurities. The *Mocha coffee* is esteemed the best, and the *Java* next; but the coffee consumed in this country is chiefly furnished from Brazil, Demarara, Jamaica, and other West India islands. Good coffee

Fig. 53.

Coffea arabica.

should be firm and solid, and heavier than water, in which it immediately sinks; a blackish-colored coffee, not compact, and floating on water, is an inferior article. *Mocha coffee* comes from Arabia, in small, yellowish, and almost round grains, and emits an agreeable odor when properly roasted. *Zanzibar* is frequently sold under the name of *Mocha*; its bean is rather small, its color the same, a little paler, of a light-yellow, slightly greenish; the grains are irregular, round, like those of *Mocha*, sometimes compressed like those of the *Bourbon* coffee; the odor and taste after torrefaction are like those of good *Mocha*. *Martinique*, a very good kind of coffee, presenting large, elongated grains, of a persistent greenish color, and covered with a silvery pellicle, which separates upon roasting; the longitudinal furrow is quite marked and very open. The coffee is rich in active principles, and has an agreeable odor on roasting. *Hayti* and *Porto Rico* are in more irregular grains, of a clearer green color, rarely provided with a pellicle. Taste and odor less agreeable than the preceding. *Bourbon*, or *Coffee of the Reunion*, is somewhat like the *Mocha*, but it is larger, not so round, equally yellowish, but less perfect in the agreeableness of its odor upon roasting. The inferior kinds of coffee improve by keeping, and if kept for several years before roasting, they yield a much more fragrant and agreeable infusion than when roasted shortly after they have been gathered. Coffee has a feeble, characteristic odor, and a rough, sweetish, peculiar taste.

A distinct species of coffee shrub is cultivated in Liberia. It is the *Coffea liberica*, Hiern. It has been introduced into the isles of the Indian Ocean, and is said to be less prone to plant disease than the common coffee shrub.

According to Dr. Stenhouse, the dried leaves of coffee, roasted, form a very agreeable infusion, and which may be used as a substitute for tea and coffee.

They contain a much larger amount of *caffeine* than the coffee-bean, with caffeic acid, and the thought was at one time entertained that they would be extensively used in the same manner as tea. According to James Motley, Esq., the natives of Sumatra cultivate the coffee plant extensively, but use only the leaves, entirely neglecting the berries. They are fastened upon strips of bamboo, held over a clear blazing fire, until they acquire a rich, brownish-green color, and become perfectly crisp and brittle, then powdered and infused in boiling water, forming a dark-brown liquid of the odor of tea, but the flavor of a mixture of tea and coffee. This is much used by them as a beverage.

Roasted coffee is a powerful deodorizer, destroying the effluvia from decomposed animal and vegetable matter.

Cultivation and Collection.—The following excellent paper, by Mr. C. G. Lloyd, is here inserted in full by permission of the author, showing the modes of raising and gathering coffee in the West Indies, as described by the author in 1892:

THE CULTIVATION OF COFFEE IN JAMAICA.—"The island of Jamaica exports each year between 800,000 and 900,000 pounds of coffee, valued last year at \$1,360,000, and the product was last year 15.7 per cent of the total exports from the island. In former years the great bulk of the coffee went to England; thus only 10 years ago, England got 73 per cent, while the United States only received 13 per cent; but beginning with 1884, the States have taken a large proportion of the product, and last year received 45 per cent, the year before 57 per cent. I am very sorry to have to report, however, that the United States only gets the poorer grades, the English paying a better price for the choice grades. The best coffee of the island is raised on the Blue Mountains, in the parishes of St. Andrew and St. Thomas, the eastern end of the island, which coffee almost entirely goes to England. I am informed by the planters of Manchester parish, who sort their coffee, that their best grades, also, go to England.

"Jamaica (and also Hayti) coffee is of an average good quality, a little stronger than Java or Mocha, but not so strong and rank as the Rio. I presume every one who knows nothing of the subject, has an idea how coffee grows, even if it is erroneous. We naturally imagine that it grows on trees like cherries, and I had expected to see a coffee plantation look like a cherry orchard. (My impressions had been formed from the picture, plate 10, of the recent French work "*Plantes Medicinales*" of Dujardin-Beaumetz and Egasse. This plate is so grossly inaccurate, not only in regard to the character and apparent size of the coffee tree, but also to the size, shape, color, and cluster of the berries, that it is a discredit to that otherwise very excellent work. A good illustration of a coffee branch is plate 106 of the German work lately completed, Köhler's *Medicinal-Pflanzen Atlas*). When I left Kingston by rail for the interior of the island, a couple of weeks before Christmas, having been told that the coffee berries were then ripe, I kept a sharp lookout for the coffee trees, but saw nothing that I could take for them. On arriving at the station, I walked along the single road or street of the little village of negro huts, and chancing to stop by the side of a copse of tangled bushes, which I took for a wild growth, I noticed a few coffee berries on the ground under the bushes, and, on investigating, found that these bushes were coffee shrubs. I tried to think of what they reminded me at home, and nothing conveys to my mind a closer comparison than a tangled undergrowth of Wahoo shrubs.

"The bulk of the coffee of Jamaica is raised by small growers—negroes, who own from $\frac{1}{4}$ to 5 acres of ground, and who plant the shrub around the place without any order or system whatever, and apparently give the shrub no attention, excepting to break off occasionally the tops when they get too high, or to cut off a few dead branches. In the statistics of the island, where the estates are specified which raise 50 acres or more of coffee, only 30 estates are named, comprising about 3,000 acres, while the acreage of small holders, less than 50 acres, is nearly 18,000. These small growers, of course, for the most part have no machinery for preparing or sorting the coffee. Almost every negro hut in the coffee districts has in the yard what they call a "barbique." It is a flat drying surface, built where the sun will strike it, and reminds one of a square tray on a large scale, built of brick with raised edges and cemented smooth. The usual size is from 12 to 20 feet square. The negroes gather the coffee berries when they get ripe, a few each week, somewhat like we would pick gooseberries, one at a time. They

put the berries into a wooden mortar and beat them, which separates the outer skins, which are washed away in buckets of water. The seeds are then put on the "barbique" to dry. Without a close examination at this stage the product resembles large grains of coffee mixed with the imperfectly separated outer skins, but on closer observation we notice that each grain of coffee is enclosed in a thick, tough, cartilaginous skin. When the coffee has been dried on the "barbique" this skin becomes brittle, and the negroes again beat it in the mortar to hull it out of this skin. Then the seeds are picked over by hand, the better part of them being sold to the little stores throughout the country, which we notice with the sign out, "Licensed to deal in agricultural products," and which pay Her Majesty's government 2 pounds each per year for the privilege. These small storekeepers send it to Kingston, from whence it is shipped abroad. Coffee merchants in Kingston and some of the merchants in the smaller towns, sort the coffee into grades according to size and weight of the berry. Most of the sorting is done by hand, though some have sizing machines, as described further on.

"On coffee plantations the same process is gone through, but on a larger scale, more systematic, and with the aid of machinery. The coffee shrub thrives best on new land, hence the portion of the plantation devoted to coffee growth is virgin soil cleared of its forest for this purpose.

"Around Mandeville, in Manchester parish, the land is now almost all pasture, and I am told that the whole of it was originally cleared off for the growth of coffee many years ago in slave times, and having raised its crops of coffee and exhausted the ground for this purpose, it was sown in Guinea grass and used for grazing. To establish a coffee plantation the land is cleared of its trees, burnt over, and cleaned up. Then it is laid out by pegs into squares of 6 feet, and young coffee sprouts about a foot high are planted near each peg. These sprouts are generally obtained from beneath old shrubs, and are adventitious growths from seed dropped from the shrub, though sometimes nurseries are established for raising the young sprouts from planted seed. In these tropical regions, weeds and vines and wild growths of all kinds spring up very quickly, and with these the planter is constantly at war. Four times a year, at least, the fields should be gone over with a hoe and the weeds cut down. In 3 or 4 years the young coffee plants begin to bear, and the shrubs continue giving crops for about 30 years. The shrub, if left to grow, would reach the height of 12 to 15 feet, but on a plantation they are topped when about 4 feet high, and kept to about this height by breaking off the tops and such suckers as appear. The branches are slender, and when the shrubs are not crowded, spread nearly horizontal. The leaves are evergreen (as, indeed, are most of the shrubs and trees in the tropics), of a firm texture, smooth and shiny above. They are opposite, oval, entire, and borne on short petioles about $\frac{1}{2}$ an inch long. They are 3 to 5 inches long, 2 to 3 inches wide, and are terminated by acuminate points.

"The flowers are white, borne in clusters of 3 to 6 in the axes of the leaves, and are exceedingly fragrant. The petals are 5, slender, spreading. The shrubs begin to blossom in February and continue in flower up to May; the fullest bloom is in March and April. Coffee does not blossom as our fruit trees, all at once, and go out of bloom in a week or two, but continues to bloom for about 4 months, and the crop in consequence ripens through the same length of time, and the planters are thus enabled to gather and care for it to better advantage than if it all ripened at once. The coffee season lasts from September to December, September and October being the principal months. The coffee berries are borne on short stalks in clusters of 3 to 6 in the axis of the leaves. When ripe they are about the size of cherries, but are oval (not globular), and slightly compressed on the side. Each berry consists of 2 seeds (familiar to us as the green coffee of commerce), each seed enclosed in a thick, tough white skin, called the parchment skin, placed in the berry with 3 flat surfaces together, and surrounded with a small quantity of sweetened pulp, the whole enclosed in a thick skin like a Malaga grape. The color of the skin, when ripe, is red, not a bright red, like a cherry, but a pale, dull red.

"The berries are picked by negro and coolie women, who go over the coffee shrubs, picking the ripe berries into baskets, and are paid by measure. The price varies according to abundance of the berries, but is regulated so that a woman

makes about 9 pence (18 cents) a day. Rats are very fond of the sweetish pulp that surrounds the coffee grains, and they climb the shrubs and gnaw off a great many berries. Birds are also said to pick them, and lizards—which are very numerous in Jamaica—are also charged with despoiling the fruit. This “rat” coffee is picked from the ground by the women, and comprises about $\frac{1}{4}$ of the crop. It furnishes a larger proportion of heavy grains than the berries gathered from the shrubs, as the rats are credited with selecting the largest and best berries, and it is kept separate in all subsequent operations. As the bulk of this coffee is supposed to be gnawed off by the rats, all coffee picked from the ground is called “rat coffee.” It costs about double to gather it as when picked from the shrubs.

“The women bring the berries to the works, where they are measured and paid for by the “Busher,” as the overseer of a coffee plantation is called. To prepare the coffee for market the berries are first run through a machine called the “pulper,” which tears off the outer skins and pulp. A “pulper” is simply a large cylindrical wheel about 3 feet in diameter and 2 feet long, covered with corrugated iron, like a nutmeg grater, and arranged so that it revolves so close to another corrugated iron surface that the berries can not go through entire, but are caught by the rough surfaces and torn to pieces, the skins and pulp being carried through, the seed dropping beneath into a tank of water. The water serves to wash the grains, and also to separate the light from the heavy coffee; the former floating, are skimmed off; the latter sinking, are taken from the tank after the water is drawn away. Heavy coffee is much the better grade, and it is kept separate from the light in all subsequent operations. At this stage the coffee seeds are still enclosed in the “parchment skins,” which are tough and can not be separated from the seeds when green; hence the next process is to thoroughly dry the seed in order to make the “parchment skins” brittle so they can be hulled off. For this purpose the seeds are spread on “barbiques” similar to those previously described, only, of course, on a larger scale. The “barbiques” of an ordinary sized plantation cover about an acre of ground, and are usually built on sloping ground and terraced. When it threatens a shower, and every evening to protect it from the rain and dews (which are heavy in the tropics), the coffee is raked into a pile in the center of each barbieue and covered with a wooden cover-shaped hopper. From 10 days to 2 weeks’ exposure to the sun on the “barbieue” will dry the seeds so that they can be hulled. The “huller” is a large wooden wheel arranged to revolve like the wheel we see in brick-yards, but running in a circular narrow trough. The coffee is placed in this trough, and the wheel constantly running over it breaks off the brittle “parchment skins,” being heavy enough for this purpose, but not so heavy as to crush the seeds. The coffee seeds are separated from the broken “parchment skins,” called trash at this stage, by being run through a “fanner,” similar to the fans of our threshing machines, which blows off the trash. There still remain closely adhering to many grains of coffee thin light gray skins called “silver skins,” which would hardly be noticed by the ordinary observer. To remove these skins and brighten the grains of coffee, it is further dried in the warehouse for 2 or 3 weeks, and again put through the “huller” and “fanner.” The next step is to separate the “pea-berry coffee.” A small percentage of the coffee berries, instead of containing the normal 2 seeds, have by abortion only a single seed. The grains of these single-seeded berries, instead of having a flat face, are rounded, and are called “pea berries.” These “pea berries” are heavy and of the best quality, and bring a better price than the best grade of flat-faced grains. To separate them the coffee is run into a cloth belt slowly revolving at a slight inclined plane, the flat-faced grains being carried over the top, the rounded “pea berries” rolling off the bottom.

“The coffee is next graded according to the size of the grains by being run through a “sizer.” This is a cylindrical screen, consisting of 4 sections of different sized meshes, the smallest holes near the top. The screen revolves at an incline, and the different-sized grains drop through the various sections according to size into bins beneath, the largest grained and best grade being carried through the cylinder. Finally the coffee is given to women who spread it on a table and pick out all the deformed or broken grains, which are called the “tringe.” The best grades of coffee are put in tierces holding about 800 pounds, and mostly shipped to England. The poorer grades and “tringe” are put into barrels or

bags for this country. I have given a description of the machinery which I saw in operation on the plantations. There are improved machines, I am told, but they are said to furnish no better results than the old ones. In concluding this article, I wish to acknowledge my indebtedness for information and other courtesies to John H. Nosworthy, the "Busher" of Somerset Plantation."

Chemical Composition.—König (*Die menschl. Nahr. und Genussmittel*, 3d ed., 1893), enumerates the following constituents of raw coffee beans, with percentage added: Water, 11.23; nitrogenous matter, 12.07; caffeine, 1.21; fat, 12.27; sugar, 8.55; nitrogen, free extractive matter, 33.79; woody fiber, 18.17; ash, 3.92. Earlier analyses, *e. g.*, that of Payen, have also demonstrated the presence of 0.003 per cent of essential oil. The amount of *caffeine* ($C_8H_{10}N_4O_2 + H_2O$), which is the most important constituent of the coffee bean (see *Caffeina*), seems to vary in the different specimens examined, from 0.23 to 2 per cent, and more, according to older analyses. More recently, however, Paul and Cownley have observed a marked uniformity in the amount of caffeine in 4 specimens analyzed, varying only from 1.10 to 1.28 per cent (*Amer. Jour. Pharm.*, 1887). Coffee is also stated to contain a small portion of citric acid. Another important constituent is *caffeotannic acid* ($C_{14}H_{18}O_8$) (which is probably the same as Payen's chlorogenic acid). Hlasiwetz has shown this compound to be a glucosid, capable of being decomposed by prolonged boiling with caustic potash in excess, and afterward treating the solution with sulphuric acid, the process yielding caffeic acid ($C_8H_6O_4$), and grape sugar. To *caffeotannic acid* Hlasiwetz assigns the formula $C_{14}H_{18}O_7$. *Caffeic acid* (Hlasiwetz), forms pale-yellow crystals, yielding, as a rule, salts of the same color. When submitted to a roasting temperature the characteristic aroma of roasted coffee is evolved. *Caffeotannic acid* is an amorphous body, somewhat gum-like, soluble in water, and both this compound and caffeic acid yield protocatechuic acid ($C_7H_6O_4$), when melted with caustic potash. It yields a green color with ferric chloride, but is not precipitated by gelatin.

The caffeic acid isolated by Stenhouse from coffee leaves, in 1854, is probably identical with the *kinic acid* obtained later by Zwenger and Siebert (in 1861), from Java coffee. The latter, by oxidation with sulphuric acid and dioxide of manganese, yielded *kinone* (*quinone*). The *viridenic acid* of Rochleder (1848), is thought to be a mixture of several acids.

By roasting, coffee acquires new properties; it expands considerably, becomes lighter by 16 or 18 per cent, has a peculiar, agreeable odor imparted to it, and a bitterish, aromatic taste, owing to the products of the torrefaction, *viz.*, a brown, aromatic oil, and a brown, bitter principle; the caffeine volatilizes to a slight extent. Paul and Cownley have shown that the amount of caffeine in roasted coffee is fairly constant, about 1.3 per cent. Palmitic, acetic, and carbonic acids are found among the products when coffee is roasted in a closed vessel. Methylamine, pyrrol, acetone, and hydroquinone, are also produced, as well as *caffeol*. The flavor of coffee depends upon its minute quantity of aromatic, volatile oil, *caffeol* ($C_8H_{10}O_2$), and if the roasting process is carried too far, this is dissipated, and the coffee then becomes bitter, without the aroma. The reactions of *caffeol* point to its being identical with saligenin methyl-ether. The roasting of coffee should be effected by a gentle heat, carefully watching the process, not driving it too rapidly; the coffee must be removed as soon as it becomes of a russet tint, friable, and emitting an agreeable aroma. Different qualities of coffee should never be roasted together, but each one separately, as one may require such a length of time for proper torrefaction as would either destroy the desired properties of the other, or, fail to develop them. To make a superior infusion, the grains should be roasted only as required for use, be at once ground, or pounded, then have boiling water poured upon the powder, in a proper vessel, the whole set over a fire and allowed to remain until the liquid begins to boil. Let it stand a couple of minutes after removal from the fire, and it is ready for use. Or, it may be made by percolation with boiling water. The soluble materials of coffee furnish the aromatic and bitter principles, for when coffee, not roasted, is exhausted by water and then roasted, it fails to impart these principles to boiling water. Roasted coffee should be of a chocolate color, should be used soon after roasting, and should be ground only as wanted, as otherwise it loses nearly all of its flavor and activity.

Adulterations.—Roasted corn, peas, beans, oats, rye, or potatoes, when added to coffee, may be known by the deep-blue, blackish-blue, or purplish-red color, which a solution of iodine imparts to the infusion; pure and roasted coffee in infusion is rendered of a deeper reddish-brown tint by the iodine (see *Chicory*). A few drops of tincture of chloride of iron, added to an infusion of coffee berries, gives a sap-green color and are recommended as a test for the genuineness of essence of coffee. Whole coffee is most generally adulterated by mixing it with the inferior grades of berries variously pigmented with coloring agents. Coffee made of clays and other like substances may be detected by the absence of pieces of the tegumentary structures, and by having no deep furrow on the face of the berry. Ground coffee has been adulterated with ground roasted dandelion root, besides the amylaceous bodies above mentioned. The husks of coffee-seed, which contain a considerable amount of the active constituent, have been sold as *sultan* or *sacca coffee*. The flavor of coffee is materially improved when it contains the seed pericarps. They should be distinguished from the fruit pericarp, which contains no caffeine.

Action, Medical Uses, and Dosage.—An infusion of roasted coffee is an agreeable stimulant, anti-soporific, and anti-emetic. It produces a mild, stimulating influence upon the organs of digestion, facilitating digestion, augmenting the biliary flow, and increasing peristalsis, thus favoring a free action from the bowels. It slightly accelerates the circulation; taken too freely, it impairs the nervous and digestive systems. The nervous symptoms are usually irritability, dejected spirits, weakness, trembling, watchfulness, mental confusion, headache, dizziness, and ringing noises in the ears; the gastric effects are flatulence, acidity, pyrosis, and bitter and sourish eructations, as well as disorders of the bowels. On the other hand, if one is accustomed to moderate amounts of the beverage, which aids digestion, headache will result if the coffee be withdrawn. Black coffee removes that drowsiness which is apt to follow a heavy dinner. A cup of strong coffee will cause a degree of wakefulness for several hours, and will frequently overcome the soporific or intoxicating effects of opium, morphine, or alcohol. In *delirium tremens* strong black coffee acts as a good and valuable hyposthenisant. In *poisoning from opium* it should always be given.

Prof. Lehman considers coffee to increase the activity of the vascular and nervous systems, while at the same time it retards the metamorphosis of plastic constituents; and which effects are owing chiefly to its empyreumatic, volatile oil. C. Voit, from more recent experiments, instituted by himself upon a dog, is led to infer that coffee rather increases the metamorphosis of nitrogenous tissue, and the excretion of urea, and attributes its principal effects to its action on the nervous system, and not to its influence on the tissue changes. The question as to whether coffee and its alkaloid hastens or retards tissue metamorphosis, is still a mooted one, but the preponderance of evidence is in favor of declaring it a restrainer of tissue changes, acting thereby as a conservator of force.

With regard to the influence of coffee upon the circulation, there is a discordance among authors, probably depending upon the quantity used, and the conditions under which it has been administered. In moderate quantity it increases the pulsations from 5 to 10 beats or more. M. Jomand, who experimented carefully upon himself, found it, in an elevated dose, to diminish the pulsations from 84 to 75. It moderates digestion, removing the sense of fullness and heaviness after meals; diminishes the sense of hunger, and powerfully aids in supporting abstinence. It lessens the amount of urea and phosphoric acid in the urine, as well as diminishes the quantity of carbonic acid gas, evacuated in the 24 hours, and has the power of retarding the disintegration of the constituents of the animal frame. It is an active diuretic, especially when its action is seconded by a white wine rich in carbonate of potassium. With some it regulates the bowels. It renders motility and exercise more energetic, and diminishes the sensation of fatigue. It produces wakefulness without being followed by fatigue, and influences the brain so that one acquires an unexpected facility for intellectual labor, conversation, etc. But when coffee is used in excess, or when only its bitter and other principles are employed, too long boiling having driven off its aroma, it proves decidedly injurious.

Some individuals, from the excessive amounts of coffee ingested, suffer from what may be aptly termed chronic coffee poisoning. The chief symptoms are a

pallid or dusky skin with emaciation, dull, expressionless features, sometimes swollen, and again looking prematurely old. Dilated pupils and a glassy stare are observed, and both the tongue and lips tremble in talking. Sleeplessness or disturbed sleep supervenes, the appetite is poor, digestion is feeble, with diarrhoea or constipation; gastralgia and other neuralgic pains are felt in various parts of the body, and dizziness and headache, with occasional spasms or convulsions, are not uncommon results. It is not unlikely that many cases of pruritis ani et vulvæ are due to even moderate coffee drinking, and when the amount consumed is very large, these symptoms are more pronounced. To complete the picture, intractable leucorrhœal discharges debilitate the woman, while sexual vigor is impaired or impotence induced in the male.

Coffee, when burned in the rooms where noxious odors are present is well known as an efficient deodorizer, and is said to exert a feeble influence over pathogenic bacteria. When partially carbonized it may be used like charcoal, as a dressing for gangrenous and other foul ulcers. Internally, coffee has proved temporarily useful in light nervous headaches, especially migraine, and in asthma, hysteria, obstinate chronic diarrhoea, and calculous nephritis. It is contraindicated in all inflammatory affections of a high grade. Dr. A. Brown, of Cincinnati, found a strong decoction of the pulverized, unroasted coffee a superior remedy in some forms of chlorosis or amenorrhœa. When fullness in the head and pain in the back were present, he gave a gentle purgative, then used the warm foot-bath, and administered the decoction in wineglassful doses every half-hour or hour. Taken in early morning, coffee is a valuable adjunct in the treatment of constipation; on the other hand, in excess it may induce that condition. Either constipation or diarrhoea are corrected by it when these troubles depend upon gastro-intestinal atony. Indigestion, when dependent upon gastric atony, or when associated with exhaustion or debility, is benefited by pure black coffee in moderate amounts. It has long enjoyed a reputation of retarding tissue waste and conserving the vital forces, and when administered in this manner in acute fevers of a typhoid character, and in convalescence from acute disorders, the effects are salutary. In these conditions it is preferable to alcohol, for it is not followed by depression like the latter agent. The well known power of coffee to sober drunken individuals is often taken advantage of by inebriates, and in small and repeated doses it stimulates the stomach and nervous system, and retards tissue change, thus assisting in the treatment of delirium tremens, in which it also tends to overcome the anemic condition of the brain. Coffee, in strong infusion, without cream or sugar, is one of the first agents to be thought of in opium narcosis, though atropine should also be cautiously used, and electricity, and particularly flagellation, resorted to; here the coffee should be given in small and frequently repeated amounts, and not in large quantities at a single dose. Both coffee and caffeine are efficient in strychnine poisoning. It is a valuable agent in congestive headache, but is asserted to aggravate where the patient is pale and the pain is simply neuralgic in character.

Coffee has also been used with much success in whooping-cough, hiccough, and in spasmodic asthma, in the form of syrup, made with the extract of coffee prepared without heat, or a strong infusion by percolation, given in small and repeated doses. Salter expresses his belief that two-thirds of the cases of asthma in which coffee is employed, are relieved by it. Dr. W. Hamilton considered the free use of strong coffee almost a specific for gout, rheumatism, and gravel. Its efficiency in the majority of cases of rheumatism, however, may be questioned. Bouchardat considered it useful in malarial districts, and stated that without it, the European colonists would have been unable to dwell in several parts of Algiers.

It has been observed by Dr. Mosely, in his *Treatise on Coffee*, that "the great use of coffee in France is supposed to have abated the prevalence of the gravel. In the French colonies, where coffee is more used than in the English, as well as in Turkey, where it is the principal beverage, not only the gravel, but the gout, those tormentors of so many of the human race, are scarcely known. Du Four relates, as an extraordinary instance of the effects of coffee in gout, the case of Mr. Deverau. He says this gentleman was attacked with the gout at 25 years of age, and had it severely until he was upward of 50, with chalk-stones in the joints of his hands and feet; but for 4 years preceding the account of his case being given

to Du Four to lay before the public, he had been recommended the use of coffee, which he had adopted, and had no return of the gout afterward." But its efficacy is not confined to the cure or mitigation of these maladies. Sir John Floyer, who had suffered under *asthma* for more than 60 years, without finding any relief from any of the numerous remedies he tried, was at length cured, when above 80 years of age, by the free use of coffee.

Through their diuretic qualities both coffee and its alkaloid have attained some distinction as remedies for *dropsies of cardiac origin*. It is adapted to cases of *heart debility*, rather than to obstructive valvular lesions, and, according to Brakenridge, it acts upon (stimulates) the renal epithelium. The whole circulatory and muscular system is aroused by them, because the nervous power to cause them to act is augmented, and they become, therefore, of more value than digitalis, which only affects the involuntary muscular fibers, inducing tonic contractions. Caffeine possesses this power to a greater degree than coffee. It should be borne in mind, however, that both coffee and tea will accomplish therapeutical results, which their alkaloid is unable to fulfil (compare *Thea: Caffeina*).

S. Martin observes that the decoction of green coffee (unroasted), when it possesses all its caffeine, forms a liquid possessing stupifying properties; while roasted coffee furnishes an excitant fluid. Strong coffee has been used successfully to control *metrorrhagia* and *post partum hemorrhage*.

Specific Indications and Uses.—Spasmodic asthmatic seizures; opium narcosis; renal torpor; cardiac insufficiency; unpleasant sense of fullness in the head and drowsiness after meals; migraine, with cerebral hyperemia; constipation, from gastric atony, when not due to excessive use of coffee.

CAFFEINA (U. S. P.)—CAFFEINE.

FORMULA: $C_8H_{10}N_4O_2 + H_2O$. **MOLECULAR WEIGHT:** 211.68.

"A feebly basic, proximate principle, obtained from the dried leaves of *Thea sinensis*, Linné (*Nat. Ord.*—Ternstroemiaceæ, or from the dried seeds of *Coffea arabica*, Linné (*Nat. Ord.*—Rubiaceæ), and found also in other plants"—(U. S. P.).

SYNONYMS: *Theine, Coffeine, Caffeia, Guaranine, Methyl-theobromine, Trimethyl-xanthine.*

Preparation.—H. J. Versman states the following to be a very profitable and simple mode of obtaining caffeine. Ten parts of bruised coffee are mixed with 2 parts of caustic lime, previously slaked. This mixture is placed in an ordinary percolator, with alcohol of 80°, until the fluid which passes through no longer furnishes evidence of the presence of caffeine. The coffee is then roughly ground and brought nearly to the state of a powder, and the refuse of the already once digested mixture from the percolator dried, and ground again, and, mixed with hydroxide of calcium, is once more macerated. The grinding is more easily effected after the coffee has been subjected to the operation of the alcohol, having lost its horny quality, and the caffeine is thus certainly extracted. The clear alcoholic fluid thus obtained is then to be distilled, and the refuse in the retort to be washed with warm water to separate the oil. The resulting fluid is then evaporated until it forms a crystalline mass, which is to be placed on a thick filter, and the moisture expressed. The moisture, after evaporation, still furnishes some caffeine. The impure caffeine is freed from oil by pressure between folds of blotting paper, and purified by solution in water with animal charcoal, and then crystallized by evaporation. Good Brazilian coffee thus yielded 0.57 per cent of caffeine.

A former Hanoverian *Pharmacopœia* directed caffeine to be made by precipitating a decoction of coffee with acetate of lead, filtering and washing the precipitate, evaporating the liquids to dryness, and, after mixing the powdered extract with sand, the mass is sublimed in Mohr's apparatus, just as in making benzoic acid (*A. J. P.*).

With a view of extracting all the caffeine from coffee, M. Pucetti tried the following method: He brought the decoction of coffee to the consistence of an extract, and treated it with alcohol, which left undissolved a resinous substance; he then dissolved a slight excess of pulverized caustic lime in the alcoholic fluid,

which, when filtered and evaporated to the necessary degree, furnished crystals of impure caffeine. This was pressed between thick linen, to get rid of the adherent mother liquor, and then dissolved in well-water, and treated with animal charcoal, by which means the alkaloid was obtained pure. One pound of coffee yielded $\frac{1}{10}$ of an ounce (about 1.5 gramme) of caffeine. He also obtained it in larger quantity from tea.

Vogel's process for procuring caffeine is to treat ground coffee with benzin; this dissolves out the caffeine and fixed oil. Distill the benzin solution to dryness, and boil the residue in water, which dissolves the caffeine, and deposits it on filtering and concentrating the liquid.

Wayne's method is to boil finely ground coffee or tea (2 parts) in washed litharge (3 parts) and water. On filtering, an almost colorless filtrate is obtained, which, by means of sulphide of hydrogen, is freed from lead, and, when sufficiently concentrated, yields caffeine in colorless crystals. Some of the alkaloid still remains in the mother liquor, and, after treatment with bone charcoal, colorless crystals may again be obtained. Another common method is that of Garot: Precipitate a coffee decoction with acetate of lead; filter; treat the filtrate with sulphide of hydrogen, to remove the lead in excess; add ammonia to neutralization; evaporate and recrystallize.

Description and Tests.—According to the *U. S. P.* caffeine occurs as "fleshy masses of long, flexible, white crystals, possessing a silky lustre, without odor, having a bitter taste, and permanent in the air. Soluble, at 15° C. (59° F.), in 80 parts of water, 38 parts of alcohol, 555 parts of ether, or 7 parts of chloroform. Also soluble in 9.5 parts of boiling water, and very soluble in boiling alcohol. When heated to 100° C. (212° F.), caffeine loses its water of crystallization, and at 229° C. (444.2° F.) it melts, forming a colorless liquid. When ignited, caffeine is completely volatilized without charring or leaving a residue. Caffeine is neutral to litmus paper. On dissolving a small quantity of caffeine in concentrated sulphuric acid, and adding a minute fragment of potassium dichromate to the liquid, the latter will acquire a yellowish-green color, which gradually becomes green. If a small quantity of caffeine be dissolved in about 1 Cc. of hydrochloric acid, a little potassium chlorate added, the whole evaporated to dryness on a water-bath, and the capsule then inverted over a vessel containing a few drops of ammonia water, the residue will acquire a rich purple color, which is destroyed by alkalis. Caffeine should dissolve in strong sulphuric or nitric acid without producing a color (absence of organic impurities). Its aqueous solution should not be precipitated by mercuric potassium iodide T.S. (absence of other alkaloids)"—(*U. S. P.*). At an elevated temperature it sublimes in needles similar to those of benzoic acid. Tannic acid precipitates it from aqueous solution. According to the analysis of theine from tea by M. Jobst, caffeine proves to be identical with it. Caffeine exists in other substances, as tea (containing 2 to 4 per cent), maté (Paraguay tea), kola nut, guarana, etc. (in the latter to the extent of 5 per cent). The taste of caffeine, though bitter, is not very unpleasant. The alkaloid may be obtained in an anhydrous state by crystallization from ether or alcohol; but, if crystallized from water, it contains a molecule of H_2O , which is expelled at, or above the boiling point of water (100° C. [212° F.]).

Chemical Composition.—It has been shown by Strecker, who produced it synthetically (1861), that caffeine is *methyl-theobromine*. When heated in the presence of barium hydroxide solution, or with solution of caustic potash in alcohol, beside a barium or potassium salt, ammonia and methylamine are produced, and from the residual matter may be obtained an amorphous basic body, soluble in both alcohol and water, but very sparingly soluble in ether, and which is known as *caffeidine* ($C_7H_{12}N_4O$). By prolonged heating the caffeidine is further decomposed and results in the production of formic acid, methylamine, ammonia, and sarkosine (methylglycocoli [$NHCH_2CH_2COOH$]). J. E. Walter (*Pharm. Rec.*, 1890), from an analysis of several kinds of unroasted coffee berries, found Costa Rica coffee to contain the largest amount of caffeine (1.24 per cent), and Mocha the least (0.54 per cent); other grades were: Rio, 1.12; Liberian Java, 1.08; Java, 0.89; Peaberry (Fenroll), 0.77 (also compare *Coffea*).

Action, Medical Uses, and Dosage.—To the nervous system caffeine is stimulant, its effects being rapidly developed. It produces a characteristic wake-

fulness, and a state of nervous unrest. Mental activity is pronounced, thought is rapid, and so great is the cerebral stimulation, that an enormous amount of brain power is developed, so that individuals are capable of prolonged and severe mental application. The reasoning faculties are sharpened, and there is also a marked capacity for physical labor. There is a great variability in its effects, as much as 23 grains having been given without marked toxicity, while doses of 8 or 9 grains have induced symptoms quite like those from alcoholic intoxication—giddiness, tinnitus, headache, tremors, unrest, wakefulness, mental confusion, delirium, and a state of drowsiness being among the phenomena observed. Diuresis is also increased. It seems not to affect the blood, though readily absorbed. Varying reports are given of its effects upon the heart. The cardiac contractions, however, are increased in force, the systole being sustained while the diastole is shortened. In consequence, there is a rise in the blood pressure. It is not thought, as formerly, that caffeine acts directly upon the cardiac muscles, like digitalis, but that it stimulates the nervous centers, thus striking at the source of cardiac power. Under its action the regularity of the heart-action is restored when disordered; the pulse rate is increased, and blood pressure augmented. These are the effects of medicinal doses, while in large amounts the heart is paralyzed by caffeine and its salts. Small doses scarcely affect the temperature, which is somewhat increased by large doses. Large doses also depress the breathing organs, while, in therapeutic doses, it acts upon the medulla, causing mere respiratory excitation. Upon the muscular structures its action is decided, increasing the power of contractility. Caffeine acts upon the secreting cells of the kidneys, stimulating them and causing diuresis—a function greatly augmented by overdoses of the drug. Both the liquid and solid constituents of the urine are increased by it, thus proving it one of the best diuretics. Partial elimination takes place by the kidneys, chiefly when toxic amounts are ingested, but in therapeutic doses the drug is destroyed in the system. That both coffee and caffeine enables one to stand severe mental and physical service is well known, and, though a question still in dispute, it is believed that this is due to its power of limiting the excretion of nitrogenous products, thus acting as a restrainer of tissue waste—a conservator of both tissue and force. This was pointed out by Lehmann (1853) and Böcker (1854) the former showing that, after the administration of a daily quantity of 6 grains of caffeine, the elimination of urea diminished from 12 to 20 per cent. Citrated caffeine, in a dose of 18 grains, caused in a woman of 30, delirium, semi-insensibility, but no headache. The feet, hands and tongue trembled, and the patient walked with a reeling gait. A cold and clammy perspiration covered the surface and the extremities were cold; the temperature remained unaffected, but the pulse was irregular and slow (55); the legs cramped; the hands and feet were slightly paralyzed; and tetanoid convulsions ensued, as well as vomiting. Intestinal pain added to the unpleasantness, but no action from the bowels was provoked. The vision was dulled though the pupils were unaffected. As is characteristic of the drug, free and frequent urination took place. In another instance an experimenter (Dr. Pratt) experienced, from 12 grains of caffeine, great mental anxiety and restlessness, persistent and rapid thinking, tremors, obstinate insomnia, and urination was frequent. These effects were developed in 2 hours after taking the drug.

Caffeine may be used to fulfil many of the uses for which coffee itself is used. It should be remembered, however, that neither fully represents the other, their effects being somewhat different, and, indeed, it is very doubtful if much caffeine remains in coffee which has been subjected to heat. The chief uses for caffeine are as a cardiac and cerebral stimulant, and as a remedy for *dropsy of cardiac origin*. As opium and coffee, and morphine and caffeine, are directly antagonistic to each other, it seems a plausible remedy for *opium narcosis*, and coffee has for years occupied the place of a standard remedy for this condition. Other and more active treatment should be instituted at the same time. Caffeine and its salts are among the most powerful of heart energizers, and may be thought in feeble and irregular action of that organ, when not due to obstruction or valvular lesions. It is preferable to digitalis in that it does not derange the stomach, is not cumulative, and acts primarily upon the nerve centers, presiding over the cardiac movements and not like digitalis upon the heart muscle alone.

Cardiac paralysis, or heart failure, may be averted by administering 5 grains every 2 hours. It is particularly adapted to that failure of cardiac power depending upon *heart dilatation, typhoid fever, pneumonia, la grippe*, and other diseases tending to implicate the heart. Administer 2 grains every 2 or 3 hours. It is more prompt than digitalis and yet more fugacious, though its diuretic power is greater. It is a valuable remedy in *dropsy*, due to feeble and irregular cardiac action, and will even act independently of its effects upon the circulation, as it has been shown to directly affect the secretory epithelial structures of the uriniferous tubules. Other forms of dropsy than the cardiac variety are little benefited by it. While it should be avoided in *acute albuminuria*, it is of signal value in the chronic form, with weak heart, provided no marked irritation of the kidneys be present. It corrects the deficient action of the renal structures. It is not without value in *uremic coma*. Caffeine, or the citrate, may be given in doses of from 1 to 5 grains every 4 hours, increasing the dose as necessary. If it tends to produce obstinate wakefulness at night, the doses may be given at short intervals in the early part of the day. It is of value in the *pulmonary congestion and pneumonia* of the aged, assisting both the heart-action and the pulmonic circulation.

Caffeine, and especially the citrated form, has attained a reputation in *migraine*. The cases most benefited are those of a hyperemic character with flushed countenance and cerebral fullness. Purely neuralgic pain, with cerebral anemia, is said to be made worse by caffeine.

The dose of caffeine ranges from $\frac{1}{2}$ to 9 grains, mixed with sugar, though the intermediate doses are to be preferred. Sodium benzoate, sodium salicylate, and antipyrin render it more soluble, and it should not be given in pill. Tanret's solution for hypodermatic use consists of sodium benzoate, Gm. 3.60 (55.5 grains); caffeine, Gm. 3 (46.3 grains); and distilled water, q.s. 10 Cc. (102.3 minims). Each cubic centimeter contains Gm. 0.30, or about 5 grains of caffeine.

Specific Indications and Uses.—Cardiac insufficiency; renal torpor, depending upon a weak heart, and dropsy from a like cause. Headache (*migraine*), with cerebral hyperemia, as evidenced by flushed face; hyperemic states of the cerebrum; opium narcosis.

Derivative of Caffeine.—**ETHOXY-CAFFEINE.**—This product has a somewhat narcotic effect upon both the brain and the spinal cord. Without materially interfering with the motor centers, or the circulation, it may cause stupor and paralysis. Diuresis, diaphoresis, and quickened heart-action, with flushed countenance, result from its physiological doses. Moderate doses induce sleep, while larger doses seem to disturb it. It may produce vomiting. In broken doses it may be administered to the extent of from 4 to 12 grains daily for the relief of *migraine*.

CAFFEINA CITRATA (U. S. P.)—CITRATED CAFFEINE.

SYNONYM: *Caffeine citrate*.

Preparation.—"Caffeine, fifty grammes, (50 Gm.) [1 oz. av., 334 grs.]; citric acid, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; distilled water (hot) one hundred cubic centimeters (100 Cc.) [3 fl \bar{z} , 183 m]. Dissolve the citric acid in the hot distilled water, add the caffeine, and evaporate the resulting solution, on a water-bath, to dryness, constantly stirring towards the end of the operation. Reduce the product to a fine powder, and transfer it to well-closed bottles"—(U. S. P.).

Commercial citrate of caffeine, so-called, is not a definite salt, but as the pharmacopœial name (citrated caffeine) would indicate, it is the alkaloid caffeine, with a portion of adherent citric acid, as shown by Hager and Haarmann. While the process above given produces a citrated caffeine only, Prof. J. U. Lloyd has shown that a true citrate of caffeine may be obtained by dissolving caffeine in chloroform and citric acid in alcohol, and mixing the two solutions, when, by evaporation, crystals of caffeine citrate result. He has further shown that this salt, so obtained, decomposes immediately in contact with water. (See *New Remedies*, 1881, p. 38).

Description.—"A white powder, odorless, having a purely acid taste and an acid reaction. One part of citrated caffeine forms a clear, syrupy solution, with about 3 parts of water. Upon dilution with water, this yields a white precipitate (caffeine), which redissolves when about 25 parts of water have been added.

It is also soluble in a mixture of 2 volumes of chloroform and 1 volume of alcohol"—(U. S. P.).

Action, Medical Uses, and Dosage.—The general action and uses of this drug are the same as those given under caffeine. This salt is used chiefly as a remedy for the *idiopathic headache*, called *migraine* (pain in the forehead). This salt is very soluble in water, and is assimilated much more readily than pure caffeine when taken into the stomach. It may be made into a pill mass with some simple extract, say 8 grains of the salt to 15 of the extract, and divided into 10 pills, of which 1 may be given every 1 or 2 hours. Pills, however, are not as desirable as other forms for administration. Or, $2\frac{1}{2}$ drachms of the salt may be dissolved in 4 ounces of simple syrup, of which 1 tablespoonful may be given as above, according to the violence of the attack. The dose of citrated caffeine ranges from 3 to 8 grains (see *Caffeina* for *Uses and Specific Indications*).

Related Salts of Caffeine.—**VALERIANATE OF CAFFEINE.** Like the citrated caffeine, this is not a definite product, and is liable to great variability in strength and quality. It has been employed in $\frac{1}{2}$ to $\frac{1}{4}$ -grain doses, administered twice daily, for the relief of *pertussis*. It is asserted to be useful in allaying the *vomiting of hysteria*.

CAFFEINE DIIODIDE-HYDRO-IODIDE ($2C_8H_{10}N_4O_2I_2 \cdot HI + 3H_2O$), or so-called *caffeine triiodide*, occurs as long prismatic crystals, of a deep-green color. It is freely dissolved by alcohol. Dose, 1 to 4 grains.

CAFFEINE SODIO-BENZOAS (N. F.), *Caffeine sodio-benzoate*.—*Formulary number, 15:* "Caffeine, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; sodium benzoate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; alcohol, a sufficient quantity. Triturate the caffeine with the sodium benzoate and a sufficient quantity of alcohol, to a smooth paste, and dry this by exposure in a moderately warm place. Rub the dry mass to a powder, and keep in well-stoppered bottles. *Note.*—The product contains 50 per cent of caffeine, and is soluble in 2 parts of water"—(Nat. Form.).

CAFFEINE SODIO-SALICYLAS (N. F.), *Caffeine sodio-salicylate*.—*Formulary number, 16:* "Caffeine, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; sodium salicylate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; alcohol, a sufficient quantity. Triturate the caffeine with the sodium salicylate and a sufficient quantity of alcohol, to a smooth paste, and dry this by exposure in a moderately warm place. Rub the dry mass to powder, and keep it in well-stoppered bottles. *Note.*—The product contains 50 per cent of caffeine, and is soluble in 2 parts of water"—(Nat. Form.).

CAFFEINA CITRATA EFFERVESCENS (U. S. P.)—EFFERVESCENT CITRATED CAFFEINE.

Preparation.—"Caffeine, ten grammes (10 Gm.) [154 grs.]; citric acid, ten grammes (10 Gm.) [154 grs.]; sodium bicarbonate, three hundred and thirty grammes (330 Gm.) [11 ozs. av., 280 grs.]; tartaric acid, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; sugar, in very fine powder, three hundred and fifty grammes (350 Gm.) [12 ozs. av., 151 grs.]; alcohol, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Triturate the solid ingredients, separately well dried, to a fine uniform powder. Mix this with alcohol, to a soft paste, and rub it through a No. 6 tinned iron sieve or enamelled colander. Then dry it, and reduce it to a coarse, granular powder. Keep the product in well-stoppered bottles"—(U. S. P.).

Action, Medical Uses, and Dosage.—An agreeable form in which to administer citrated caffeine, the dose being a teaspoonful dissolved in water, and drunk while effervescing (see *Caffeina*).

CAHINCA.—CAHINCA-ROOT.

The bark of the root of *Chiococca racemosa*, Jacquin.

Nat. Ord.—Rubiaceæ.

COMMON NAMES: Snowberry, Cluster-flowered snowberry, Cahinca, Cainca, David's root.

Botanical Source.—A somewhat climbing shrub, with a round, branched root, and a stem 8 to 12 feet high, arborescent, with branches opposite. The leaves are ovate, pointed, and smooth, with an uninterrupted margin; the stipules are short, pointed, and joined together at the base. The flowers are white, without odor, but subsequently become yellowish and redolent, and are borne in

short, axillary, 1-sided racemes. The calyx is 5-cleft; the corolla funnel-shaped; the stamens 5. The fruit is a small, roundish, compressed, white berry. The *C. anguifuga*, Martius, and *C. densifolia*, Martius, are varieties possessing similar properties.

History and Description.—This plant, sometimes called *Snowberry*, is a native of the West Indies, South America, and also of the sea-coast of Florida. In Brazil the root is known as "*raiz preta*" (black root). In that country the roots of *Chiococca anguifuga*, Martius, and *Chiococca densifolia*, Martius, are employed under the names *canina* and *caninana*. The root as found in commerce, is in small round pieces of different sizes and lengths, flexuous, with longitudinal rugæ and a few rough spots, and brownish-black or grayish-brown, having its thin, cortical portion of a reddish-brown color, fragile, of a disagreeable odor, and a coffee-like taste, succeeded by a pungent nauseousness; its internal, woody portion is without taste. The bark is the medicinal part, and yields its properties to water or alcohol.

Chemical Composition.—Besides *cahincic acid* ($C_{20}H_{34}O_{12}$), the root-bark contains, according to Pelletier, gummy, oily, and coloring matters, the nature of which is not well understood. Its most important medicinal constituent is the *cahincic acid*, or *cahincin*. It forms in silky-white, acicular crystals, sparingly soluble in ether and cold water (1 in about 600). It dissolves in hot alcohol, from which it again crystallizes upon cooling. It is a permanent body, and is supposed to exist partly free in the root, and also as a calcium subcahincate. It is odorless, and has a slowly developing, yet excessively bitter taste. By boiling with hydrochloric acid it is split into grape sugar and other bodies, chief among which is *cahincetin* (*caincetin*) ($C_{22}H_{34}O_8$), a principle soluble in alcohol, in which on adding water, it gelatinizes. The root contains a tannin which was pointed out, in 1851, by Rochleder and Hlasiwetz, to be *caffeo-tannic acid*. A body, named *cahincigenin*, having the formula $C_{14}H_{24}O_8$, and butyric acid, are produced when *cahincetin* and caustic potash are melted together.

Action, Medical Uses, and Dosage.—In medium doses it augments the urinary discharge, slightly accelerates the action of the heart, and increases the peristaltic action of the bowels; and if the body be kept warm, and warm infusions be drank, instead of purging it will produce perspiration. In large doses it produces the most violent emetic and drastic effects. It has been found efficient in *dropsy*, uncomplicated with acute renal disorder, *amenorrhœa*, *rheumatism*, *syphilis*, and *osteocopus*, and in Brazil is used as an antidote to *poisonous snake-bites*. From 20 to 60 grains of the powdered root-bark will act as a purgative and diuretic; or from 10 to 20 grains of an aqueous or spirituous extract. It may also be used in decoction or tincture (root, ʒviii to alcohol 98 per cent, Oj). Tincture, 1 to 5 drops.

Specific Indications and Uses.—Scanty urine with a sense of fullness in the loins; edematous feet and eyelids.

CALAMUS (U. S. P.)—SWEET FLAG.

The rhizome of the *Acorus Calamus*, Linné.

Nat. Ord.—Aroideæ.

COMMON NAMES: *Sweet flag*, *Calamus*.

ILLUSTRATIONS: Willdenow, *Sp. Plants*, II., 199; Woodville, *Med. Bot.*, 248; Barton, *Med. Bot.*, II, 63; Bentley and Trimen, *Med. Plants*, 279.

Botanical Source.—Calamus is an herbaceous, perennial, aromatic, flag-like plant, flourishing in wet situations. The leaves are long, radical, and sword-like, erect, bright green, but reddish or pink at the base, where they are ensheathing. The stalk is triangular, giving off from one side a spadix bearing thickly crowded, perfect greenish-yellow flowers.

History.—Calamus grows in muddy places, in swamps and meadows, along streams and the borders of lakes, in nearly all parts of India and Central Asia (from whence it has spread to other parts of the globe), Southern Siberia, Japan, China, Europe, and North America. In Ceylon and Burmah it is cultivated to some extent. Persian and East Indian calamus is said to be of better quality

than that of other parts of the world. In America it blooms from April to July. The rhizome should be gathered in early spring or in October and November, freed from dirt and its bitter rootlets, and dried quickly in a gently warmed room. The leaves also possess the aromatic properties of the rhizome, but to a lesser degree, and are not employed as a medicine. This drug and the calamus of Scripture are probably identical. Sweet flag has long been a popular remedy in India, where large quantities of it are yearly sold in the bazaars. According to Ainslie (1813), it is there considered so valuable in the bowel disorders of children that a penalty is incurred by any pharmacist who will not open his shop in the night to sell it when called upon to do so (*Pharmacographia*). The Hindus regard it as an emetic in large, and stimulant, tonic, and carminative in small doses, and employ it in stimulant doses in paralysis and other nervous disorders. The Mahometans use it internally in calculous troubles, and advise its use for teething children to bite upon. An infusion is considered in Ceylon as an efficient anthelmintic for children (Dr. Ondaatji, Col. Surg. of Ceylon). Evers found the decoction useful in diarrhoea and dysentery, and infantile bronchitis, and often used it personally for cold in the chest. Watts states that it is useful for distressing cough (Dymock, *Mat. Med. Western India*).

Description.—The rhizome, or part employed, is subspherical, creeping, fleshy, thick, and rather spongy, and gives off numerous rootlets. It is often several feet in length, and shows upon its upper surface triangular leaf-scars, which are occasionally apparently hairy (when dried), and on the lower surface may be seen several zigzag or wavy lines composed of circular dots, indicating where the rootlets were attached. The rhizome is occasionally wrinkled longitudinally, and has a brownish-yellow color (pinkish shortly after being peeled). It has a peculiarly agreeable, aromatic odor, and an aromatic, bitterish, pungent taste. The dried roots of commerce are from 3 to 6 inches long, light-brown or fawn colored, of a whitish or slightly roseate hue internally, corrugated outside, and break with a spongy or cork-like fracture. It has the peculiar warm, pungent taste possessed by the green rhizome. It loses its strength with age, and is liable to destruction by worms. Water or alcohol takes up its medicinal virtues. To preserve it, it should not be peeled. The *U. S. P.* describes it as follows:

"In sections of various lengths, unpeeled, about 2 Cm. ($\frac{3}{4}$ inch) broad, subcylindrical, longitudinally wrinkled; on the upper surface marked with leaf-scars forming triangles, and on the lower surface with the circular scars of the rootlets in wavy lines; externally reddish-brown, somewhat annulate from remnants of leaf-sheaths; internally whitish, of a spongy texture, breaking with a short, corky fracture, showing numerous oil cells and scattered wood bundles, the latter crowded within the subcircular endoderm. It has an aromatic odor, and a strongly bitter taste"—(*U. S. P.*).

Chemical Composition.—Trommsdorff found it to contain essential oil, resin, extractive with chloride of potassium, gum with phosphate of potassium, starchy matter, woody fiber, and water. The oil is lighter than water, and is pale yellow, very odorous and pungent. Kurbatow (1873) found this oil to contain a hydrocarbon ($C_{24}H_{34}$), which, with hydrochloric acid, formed a crystalline compound, and another hydrocarbon refusing to combine with this acid (*Pharmacographia*). Faust (1867) obtained a bitter glucosid, of a brownish color, and of a semi-fluid consistence, which he named *acarin* ($C_{24}H_{34}O_8$). It contains no nitrogen when purified, is insoluble in water and benzol, but dissolves in alcohol, methylic alcohol, chloroform, and ether. Flückiger (*Pharmacographia*), by precipitating a decoction with tannin, and treating the precipitate with litharge, and exhausting the residue with chloroform, obtained a minute quantity of a very bitter, crystalline solid. Thoms (1886) thought to have obtained a crystalline alkaloid, *calamine*, which, however, in 1888 he declared to be *trimethylamine*. This result is supported by the observation of Kunz (1888) who found *choline* to exist in calamus root.

Action, Medical Uses, and Dosage.—The root is carminative, slightly tonic, and excitant, and forms a useful adjunct to other tonics and stimulants. It may be used in cases of *flatulent colic*, *atonic dyspepsia*, *feebleness of the digestive organs*, and to aid the action of cinchona or quinine in *intermittents*. It forms an excellent substitute, in syrup, for Godfrey's cordial. In *flatulent colic* of infants

it is best combined with magnesia. Externally, it is a valuable application to *indolent ulcers*, and to keep up the discharges from *blistered surfaces* and *issues*. Dose of the infusion made by scalding 4 drachms of the root, coarsely bruised, in 8 fluid ounces of water, from 4 to 6 fluid ounces; of the powdered root, 20 to 40 grains; a tincture may be prepared from 1 part of the root and 5 parts of alcohol. Dose, from 5 to 30 minims.

CALCI BROMIDUM (U. S. P.)—CALCIUM BROMIDE.

FORMULA: CaBr_2 . MOLECULAR WEIGHT: 199.43.

SYNONYM: *Bromide of calcium*.

Preparation.—This salt may be formed by the decomposition of bromide of sulphur with lime. In 1872, Mr. J. R. Mercein recommended that it be prepared from hydrobromic acid and carbonate of calcium, hydrobromic acid being first made by passing sulphide of hydrogen through bromine beneath water, and then the carbonate of calcium to be subsequently decomposed with this solution. To this end, take any convenient quantity of solution of hydrobromic acid, place it in a porcelain evaporating dish capable of holding 4 times the bulk, and then add carbonate of calcium, with stirring, as long as effervescence continues, then warm it, filter, and evaporate the filtrate to dryness.

Description.—Bromide of calcium, by evaporation from its aqueous solution, forms silky needles which, according to Watts, are a hydrated bromide. In many respects it resembles calcium iodide and calcium chloride. The *U. S. P.* describes it as "a white, granular salt, odorless, of a sharp, saline taste, and very deliquescent. Soluble at 15° C. (59° F.), in 0.7 part of water, and in 1 part of alcohol; much more soluble at a boiling temperature. At 680° C. (1256° F.), the salt fuses, and at a higher temperature it is partly decomposed, with loss of bromine. The salt is neutral to litmus paper"—(*U. S. P.*).

The impurities more apt to be encountered in this salt are hydroxide of calcium and calcium oxybromide (calcium bromate). Either may be separated by dissolving the salt in alcohol, and then filtering, as these impurities are insoluble in alcohol. Other substances, such as chlorides, nitrates, bromates, etc., are not likely to occur in any considerable amount. "Calcium bromide should be kept in well-stoppered bottles"—(*U. S. P.*).

Tests.—"The aqueous solution (1 in 20) of the salt yields, with ammonium oxalate T.S., a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If to 5 Cc. of the aqueous solution a few drops of chloroform be added, and then 1 Cc. of chlorine water, bromine will be liberated, and, on agitating the mixture, will dissolve in the chloroform with a yellow or brownish-yellow color. If 1 Gm. of the salt be dissolved in 20 Cc. of the water, it should form a clear, colorless solution, leaving no residue (absence of insoluble impurities). If to 5 Cc. of this aqueous solution, slightly acidulated with hydrochloric acid, an equal volume of hydrogen sulphide T.S. be added, neither coloration nor turbidity should be perceptible (absence of arsenic, lead, etc.). The addition of ammonium sulphide T.S. to the aqueous solution should not produce any color or turbidity (absence of iron, aluminum, etc.). If 5 Cc. of the aqueous solution (1 in 20), slightly acidulated with acetic acid, be completely precipitated with ammonium oxalate T.S., the filtrate should, on evaporation, leave not more than a trace of fixed residue (limit of magnesium and alkalies). If diluted sulphuric acid be dropped upon the salt, the latter should not at once assume a yellow color (absence of bromate). If to 5 Cc. of the aqueous solution (1 in 20) a few drops of starch T.S. be added, and then chlorine water, drop by drop, no blue color should appear (absence of iodide). No turbidity should be produced if 0.2 Cc. of barium chloride T.S. be added to 5 Cc. of the aqueous solution (absence of sulphate). If 1 Gm. of the salt be mixed with 0.5 Gm. of iron filings and 0.5 Gm. of powdered zinc, and heated in a test tube with 5 Cc. of sodium hydrate T.S., no ammoniacal vapors should be evolved (absence of nitrate or nitrite). If 0.25 Gm. of the well-dried salt be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. added, it should require 25 Cc. of decinormal silver nitrate V.S. to produce a permanent red color (corresponding to 99.7 per

cent of the pure salt, a greater amount indicating presence of chloride, a smaller amount other impurities"—(U. S. P.).

Action, Medical Uses, and Dosage.—The attention of the profession was directed to bromide of calcium, in 1871, by Dr. W. A. Hammond, as a sedative and hypnotic in certain nervous maladies, in lieu of bromide of potassium and other bromides. He has found it beneficial, acting promptly, in cases of *delirium*, *insomnia* due to business anxieties, or intense mental labor or excitement; in exhausted and irritable conditions of the nervous system, as indicated by *head-ache*, *vertigo*, *wakefulness*, etc., so frequently observed among hysterical women; in *epilepsy* occurring in very young infants, that resisted the bromide of potassium. He has likewise derived advantage from its use in *cerebral congestion*, both the active and passive forms, and in *locomotor ataxia*. It is much more prompt in its action than the other bromides. Its dose is from 15 to 30 or more grains for an adult. He has given the following as an eligible formula: Take of bromide of calcium 1 ounce, syrup of lactophosphate of calcium 4 fluid ounces; mix. The dose of this solution is 1 teaspoonful in a little water, to be repeated 3 times a day. This bromide will be found useful in nearly all cases in which the other alkaline bromides are indicated, in most instances acting more promptly, with greater efficiency, and with less tendency to acneiform eruptions.

Specific Indications and Uses.—Anemia; nervous debility from malnutrition.

CALCI CARBONAS PRÆCIPITATUS (U. S. P.)—PRECIPITATED CALCIUM CARBONATE.

FORMULA: CaCO_3 . **MOLECULAR WEIGHT:** 99.76.

SYNONYMS: *Calcaria carbonica præcipitata*, *Creta præcipitata*, *Precipitated carbonate of calcium*, *Precipitated chalk* (compare *Creta præparata*).

Preparation—Precipitated chalk may be made by dissolving 5 ounces of chloride of calcium (obtained by dissolving pieces of marble in diluted hydrochloric acid, leaving the former in excess), and 13 ounces of carbonate of sodium, each, in 2 pints of boiling distilled water, mixing the two solutions, and when the precipitate has subsided, collecting it on a calico filter, washing it with boiling distilled water, until the washings cease to give a precipitate with nitrate of silver, and then drying the product at a temperature of 100°C . (212°F .), or on bibulous paper. It forms a very pure article. This process is in accordance with that of the *British Pharmacopæia*. The reaction may be expressed thus: $\text{CaCl}_2 + \text{Na}_2\text{CO}_3 = \text{CaCO}_3 + 2\text{NaCl}$. The calcium carbonate is precipitated while the sodium chloride is left in solution, though the precipitated salt, even when repeatedly washed, is apt to retain a small amount of common salt. If precipitated in cold instead of hot water, the product is a light and bulky, flocculent article, difficult to deprive of its impurities, even by thorough washing. Other alkaline carbonates produce with soluble calcium salts, a precipitated carbonate of calcium. When ammonium carbonate is employed, the product is deprived of its impurities with less difficulty than when sal soda is used. It is sometimes adulterated with calcium sulphate (gypsum).

Description and Tests.—"A fine, white powder, without odor or taste, and permanent in the air. Nearly insoluble in water; the solubility is increased by the presence of ammonium salts, and especially by carbonic acid; alkali hydrates diminish it. Insoluble in alcohol. In diluted acetic, hydrochloric, or nitric acid, it is completely soluble, with effervescence. When heated to redness with access of air, the salt loses carbon dioxide, and a residue of calcium oxide remains"—(U. S. P.).

"For applying tests of identity and of purity, boil 6 Gm. of calcium carbonate with a mixture of 50 Cc. of diluted acetic acid, and 50 Cc. of water, allowing the liquid to cool, and filter. In this solution, ammonium oxalate T.S. produces a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If from 20 Cc. of this solution the calcium be completely precipitated by a slight excess of ammonium oxalate T.S., the filtrate should, on evaporation, leave only a trace of fixed residue (limit of magnesium and alkalies). If 10 Cc. of the solution be slightly acidulated with acetic acid, no immediate turbidity should be produced by the addition of 0.5 Cc. of barium chloride T.S. (limit of sulphate).

If to 10 Cc. of the solution, slightly acidulated with nitric acid, 0.1 Cc. of silver nitrate V.S. be added, and the precipitate, if any, removed by filtration, the filtrate should remain perfectly clear upon the addition of more silver nitrate V.S. (limit of chloride). Addition of ammonia water should not produce any turbidity in the solution (absence of iron, aluminum, phosphate, etc.). If to the solution, slightly acidulated with acetic acid, an equal volume of hydrogen sulphide T.S. be added, neither color nor turbidity should be produced (absence of arsenic, lead, etc.). If 1 Gm. of the salt be agitated with 50 Cc. of water, the filtrate should not show an alkaline reaction with litmus paper, and, on evaporation, should not leave more than a trace of residue (limit of soluble impurities)"—(U. S. P.).

Action, Medical Uses, and Dosage.—For general uses precipitated chalk does not possess any marked advantage over prepared chalk, though some dentists prefer it to the latter as a dentifrice. On the other hand, the amorphous creta preparata is to be preferred for internal use (see *Creta Preparata*). The dose of precipitated chalk is the same as for prepared chalk.

CALCI CHLORIDUM (U. S. P.)—CALCIUM CHLORIDE.

FORMULA: CaCl_2 , MOLECULAR WEIGHT: 110.65.

"Calcium chloride, rendered anhydrous by fusion at the lowest possible temperature. It should be kept in well-stoppered bottles"—(U. S. P.).

SYNONYMS: *Calcium chloratum*, *Chloridum calcicum*, *Calcaria muritica*.

Source and Preparation.—Calcium chloride is present in sea-water and in the waters of many mineral springs. It is obtained largely as a by-product in the production of potassium chlorate and ammonia water. When the latter is made by double decomposition of ammonium chloride and calcium hydroxide, calcium chloride results, thus: $(\text{NH}_4\text{Cl})_2 + \text{Ca}(\text{OH})_2 = \text{CaCl}_2 + (\text{NH}_4\text{OH})_2$. It may be prepared by dissolving fragments of chalk, marble, or other forms of calcium carbonate, in hydrochloric acid, allowing chlorine gas to pass into the solution to oxidize the iron and manganese, then adding an excess of milk of lime, filtering, and finally evaporating the filtrate to dryness over a fire.

The commercial form is unsuited for chemical uses, such as drying gases, etc. It may, however, be rendered useful for this purpose by fusing in a porcelain or iron evaporating dish over a direct fire, and allowing it to become dry, and, while still hot, transferring to and securing it in glass-stoppered bottles.

Description and Tests.—Calcium chloride may be obtained as transparent, colorless, deliquescent, striated, prismatic crystals, having the composition: $\text{CaCl}_2 + 6\text{H}_2\text{O}$; but as met with in commerce it is in amorphous masses or lumps. On account of its remarkable affinity for water, it is used in the laboratory for abstracting moisture from gases. The Pharmacopœial salt is thus described: "White, slightly translucent, hard fragments, odorless, having a sharp, saline taste, and very deliquescent. Soluble, at 15°C . (59°F .), in 1.5 parts of water, and in 8 parts of alcohol, in 1.5 parts of boiling alcohol, and very freely in boiling water; insoluble in ether. Below a red heat the salt fuses, and, on cooling, solidifies without change in composition; but at a higher temperature, especially if kept in fusion for some time, a portion is decomposed and calcium oxide formed. When perfectly pure, the salt dissolves in water without residue, and the solution is strictly neutral to litmus paper. When the salt is overheated in fusing, the solution has an alkaline reaction, and a small residue is left, which is soluble in hydrochloric acid. The aqueous solution (1 in 20) yields, with ammonium oxalate T.S., a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid. With silver nitrate T.S. it yields a white precipitate insoluble in nitric acid. The aqueous solution (1 in 20) should remain clear upon addition of ammonia water (absence of iron, aluminum, etc.), or of barium chloride T.S. (absence of sulphate). If from 20 Cc. of the solution the calcium be completely precipitated by ammonium oxalate T.S., the filtrate should, on evaporation, leave not more than a trace of fixed residue (limit of magnesium and alkalis). If 5 Cc. of the aqueous solution, acidulated with hydrochloric acid, be mixed with an equal volume of hydrogen sulphide T.S., neither color nor turbidity should appear (absence of arsenic, lead, etc.). No turbidity should be produced

by the addition of 0.5 Cc. of potassium dichromate T.S. to 5 Cc. of the aqueous solution (absence of barium)"—(U. S. P.). Calcium chloride has been employed in preparing artificial mineral waters, and, mixed with snow or ice, forms a powerful freezing mixture, producing a temperature as low as -48°C. (-54.4°F.).

LIQUOR CALCII CHLORIDI.—The *British Pharmacopœia* directs calcium chloride, 88 grains; distilled water, 1 ounce. Solve. It may also be prepared by dissolving in 1 ounce of distilled water 226 grains of fused calcium chloride, and filtering the solution.

Action, Medical Uses, and Dosage.—Chloride of calcium in small doses promotes secretions from the skin, kidneys, and mucous surfaces. Over the glandular system and lymphatics it exerts a specific influence, acting as a powerful resolvent in reducing hard lymphatic and glandular enlargements. Nausea, vomiting, sometimes purging, quickened pulse, præcordial anxiety, faintness, muscular weakness, tremors, and vertigo are the effects of large doses. Toxic doses act powerfully upon the nervous system, producing tremors, contracted pulse, spasms, paralysis, unconsciousness and death. Both internally and by means of a bath, chloride of calcium has a deserved reputation as a remedy in *scrofulous conditions*, with marked involvement of the lymphatic glands. *Goitre*, *paralysis* and *arthritic affections* have been successfully treated with it, and it is asserted to have cured *tuberculosis mesenterica*—a mistake probably—but there is no reason why it should not exert a kindly action in this disorder. The conditions pointing to its selection are given below. Add 1 drachm of fresh calcium chloride to 1 pint of distilled water, cork the vessel well, and give teaspoonful or table-spoonful doses of the solution in a wine-glassful of cold water, 3 or 4 times a day. Of the liquor calcii chloridum, 10 to 60 drops in milk or water.

Specific Indications and Uses.—Lymphatic glandular enlargement; slow inflammations, with cacoplastic deposits; bad breath, with tongue dirty with pasty coat (Scudder); dyspepsia of scrofulous children, with enlarged tonsils, bad breath, irregular stools, capricious appetite, restlessness in sleep; strumous skin diseases.

CALCII HYPOPHOSPHIS (U. S. P.)—CALCIUM HYPOPHOSPHITE.

FORMULA: $\text{Ca}(\text{PH}_2\text{O}_2)_2$. **MOLECULAR WEIGHT:** 169.67.

SYNONYMS: *Hypophosphite of lime*, *Calcarium hypophosphorosum*, *Calcium hypophosphorolum*, *Hypophosphis calcicus*, *Hypophosphite of calcium*.

Preparation.—On a large scale this salt is prepared by acting upon finely divided phosphorus, with milk of lime, at the same time exposing the mixture to the air and frequently agitating it until the phosphorus is all consumed. A complicated reaction ensues, whereby phosphide of hydrogen is formed as a by-product, which ignites spontaneously in contact with the air, forming white rings of pentoxide of phosphorus and water as the products of combustion, consequently the operation, which at best is unpleasant, should be conducted under a hood, or in the open air. Prof. Procter (1858) proposed a process essentially as follows: Into a deep boiler introduce a smooth milk of lime, prepared with 5 gallons of water and 4 pounds (av.) of quick lime. Boil with this milk 1 pound of phosphorus, adding boiling water occasionally to preserve the full amount of liquid, and continue heating until all the phosphorus has become oxidized, and until it no longer evolves the odor of hydrogen phosphide. Then filter the mixture, wash the residue with water, evaporate to 6 pints, and again filter to remove the calcium carbonate and calcium hydroxide, and evaporate until a pellicle forms, when it may be set aside to crystallize, or, if desired in granulated form, it may be so obtained by stirring while still hot, and continuing the evaporation. When prepared according to this process, a large amount of the phosphorus is oxidized, forming phosphoric acid, which unites with the superabundant lime to form insoluble phosphate of calcium. Much of this loss may be averted by rendering the phosphorus spongy by passing a current of air into the water in which it is immersed.

In this way it may be made to unite with the lime at a much lower heat, or even at 15°C. (59°F.), though most readily at about 54°C. (about 129°F.); but little hydrogen phosphide is then evolved.

Description and Tests.—The *U. S. P.* describes this salt as follows: "Colorless, transparent, monoclinic prisms, or small, lustrous scales, or a white, crystalline powder, odorless, having a nauseous, bitter taste, and permanent in the air. Soluble, at 15° C. (59° F.), in 6.8 parts of water, and in 6 parts of boiling water; insoluble in alcohol. When heated in a test-tube, the salt decrepitates, and above 300° C. (572° F.) it begins to decompose, giving off water, and emitting inflammable gases (hydrogen and hydrogen phosphide), and leaving a residue of calcium pyrophosphate and metaphosphate, with some red phosphorus. The aqueous solution (1 in 20) is neutral to litmus paper, and yields, with ammonium oxalate T.S., a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. The aqueous solution, slightly acidulated with sulphuric acid, yields, with silver nitrate T.S., a precipitate which is white at first, but rapidly turns brown and black by separation of metallic silver. With copper sulphate T.S., on gentle heating, a reddish-brown precipitate of copper hydride is formed. When the aqueous solution is added, drop by drop, to mercuric chloride T.S., at first a white precipitate of mercurous chloride is formed, which, as soon as the hypophosphite solution is added in excess, turns gray from reduction to metallic mercury. If 1 Gm. of the salt be dissolved in 20 Cc. of water, no insoluble residue should be left (absence of phosphate, sulphate, and other insoluble impurities). In this solution no precipitate should be produced by the addition of lead acetate T.S. (absence of soluble phosphate); nor, after acidulating with hydrochloric acid, by barium chloride T.S. (absence of soluble sulphate); nor by an equal volume of hydrogen sulphide T.S. (absence of arsenic, etc.). On adding to 5 Cc. of the solution (1 in 20) 1 Cc., each, of ammonium chloride T.S. and ammonia water, and 3 Cc. of ammonium carbonate T.S., applying a gentle heat for a few minutes, and then filtering, not more than a very slight turbidity should be produced upon adding to the filtrate a few drops of sodium phosphate T.S. (limit of magnesium). If 0.1 Gm. of the salt be dissolved in 10 Cc. of water, then mixed with 10 Cc. of sulphuric acid and 50 Cc. of decinormal potassium permanganate V.S., and the mixture boiled 15 minutes, it should require not more than 3 Cc. of decinormal oxalic acid V.S. to discharge the red color (corresponding to at least 99.68 per cent of the pure salt)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Calcium hypophosphite belongs to the class of alteratives and restoratives. Undoubtedly much of its value is due to the phosphorus combined in it, but its whole action can not be attributed to that element. It is adapted especially to those conditions of innervation, with great depression of the nervous powers—a lack of nerve force, which so often seems to be the chief trouble in innumerable chronic diseases. It is of considerable value in *scrofulosis*, and in *incipient consumption* it was regarded by Prof. J. M. Scudder as one of the most certain agents he had ever employed (*Dis. of Child.*, p. 69). It tones the digestive organs, relieves pulmonary atony and irritation, checks the cough, gives freer respiration, and improves blood-making and nutrition. It is a constituent of the compound syrup of the hypophosphites. Dose, 2 to 10 grains, 2 or 3 times a day.

Specific Indications and Uses.—Deposits of aplastic or cacoplastic material in connective tissue, resulting in slight inflammations; tuberculosis; phthisis pulmonalis, especially in early stage; marked nervous depression.

CALCI IODIDUM.—CALCIUM IODIDE.

FORMULA: CaI_2 . MOLECULAR WEIGHT: 292.97.

SYNONYMS: *Iodide of calcium*, *Calcium iodatum*, *Iodide of lime*.

Preparation.—Iodide of calcium may be prepared by acting upon a solution of ferrous iodide with milk of lime, and filtering and evaporating the solution. It may also be prepared by making a solution of slaked lime (or carbonate of calcium may be employed), in hydriodic acid, and evaporating to crystallization.

Description.—Iodide of calcium crystallizes in lustrous, pearly lamellæ, which are exceedingly deliquescent. When pure it should be white, but as ordinarily prepared, is yellowish. Water and alcohol freely dissolve it, and the solution of the salt itself will dissolve iodine. In contact with the atmosphere partial

decomposition of its solution takes place, with the formation of some carbonate of calcium. This salt does not easily crystallize, and is not so stable as potassium iodide. It is usually found in commerce as a powder.

Action, Medical Uses, and Dosage.—Large doses of this salt are irritant. Putrefactive changes are arrested, and the feces deodorized by it. Material doses (1 to 3 grains 3 times a day), have been used to check *suppurative discharges*, at the same time deodorizing them, to arrest *erysipelatous inflammation*, and to promote resolution in *scrofulous ulcerations*. Calcium iodide acts chiefly upon the glandular system, and has been preferred by some over other iodine preparations in *pulmonary consumption*. It is especially serviceable in *enlarged cervical lymphatics*, and in *enlargements of the bronchial glands* as evidenced by persistent cough. Among scrofulous children, a *chronic bronchitis* with the above characteristics is likely to occur; 1 to 3-grain doses of the 1 x, 2 x, or 3 x trituration may be given several times a day. A dark-colored iodide of lime has been lauded as a remedy for *croup*.

Related Salt.—**CALCII IODAS.** *Calcium iodate, Iodate of lime.* Formula $\text{Ca}(\text{IO}_3)_2 + 6\text{H}_2\text{O}$. Molecular weight, 496.49. This salt may be prepared by acting upon iodine with chlorinated lime in excess, in the presence of water. When decolorized, hydrochloric acid sufficient to slightly acidulate, is added, the mixture heated to 100°C . (212°F .), filtered, and allowed to crystallize. It may also be prepared by mixing gradually an excess of aqueous solution of chlorinated lime and iodine dissolved in alcohol. When this process is employed, iodine chloride is liable to be formed if the temperature is much increased. This salt exists naturally in the waters of the sea. It forms slowly efflorescing, flat, acicular crystals, without color, and presenting a shining appearance. It is not readily soluble in water, and scarcely at all in alcohol. On the addition of sulphurous acid, iodine is set free. This salt has been used but little in medicine, though it is said to reduce temperature and augment the appetite in *fevers*, when administered 3 times a day in from 2 to 4-grain doses. On account of its reputed antiseptic qualities, it has been proposed as a food preservative.

CALCII PHOSPHAS PRÆCIPITATUS (U. S. P.)—PRECIPITATED

CALCIUM PHOSPHATE.

FORMULA: $\text{Ca}_3(\text{PO}_4)_2$. **MOLECULAR WEIGHT:** 309.83.

SYNONYMS: *Calcium phosphoricum, Precipitated phosphate of lime, Bone phosphate of lime, Bone phosphate, Calcaria phosphorica, Calcii phosphas (Br.).*

Preparation.—Take of finely powdered calcined bone, 2 ounces; hydrochloric acid, 4 ounces; ammonia water, 6 fluid ounces; distilled water, a sufficient quantity. Digest the calcined bone in the hydrochloric acid diluted with 8 fluid ounces of the water, until it is all dissolved. Then filter the solution and add to it 8 fluid ounces more of the water, and afterward the water of ammonia, gradually adding it until the fluid acquires an alkaline reaction. The precipitate thus obtained must be collected on a calico filter, and, to remove any ammonium chloride that may be present, washed with boiling distilled water as long as the liquid which passes through occasions a precipitate when dropped into a solution of nitrate of silver acidulated with nitric acid. Dry the washed product at a temperature not exceeding 100°C . (212°F .).

The U. S. P. (1870), and the *British Pharmacopæia*, direct bone ash, 4 ounces; water, 2 pints; hydrochloric acid, 6 (Br.), [8 (U. S.)] ounces; solution of ammonia, 12 ounces (or a sufficient amount), and distilled water, q. s. After digesting the bone-ash in the diluted hydrochloric acid, the solution is boiled (Br.) for a few moments, after which the procedure is essentially that given above. The *German Pharmacopæia* prepares a more soluble salt by precipitating with sodium phosphate a solution of sodium chloride. Its formula is $\text{CaHPO}_4 + 2\text{H}_2\text{O}$.

Description and Tests.—“A light, white, amorphous powder, odorless and tasteless, and permanent in the air. Almost insoluble in cold water; partly decomposed by boiling water, which dissolves out an acid salt; almost insoluble in acetic acid, except when freshly precipitated; easily soluble in hydrochloric or nitric acid; insoluble in alcohol. At an intense white heat the salt fuses without decomposition. When moistened with silver nitrate T.S., a yellow color is assumed by the salt either before or after ignition (distinction from acid calcium phosphate, which, after ignition, when moistened with silver nitrate, remains white). For applying tests of identity and purity, shake 2 Gm. of the salt with

20 Cc. of water, and add nitric acid, drop by drop, until solution is effected; and then add water to make the liquid measure 40 Cc. No effervescence should occur on adding the acid (absence of carbonate). From a portion of this solution the salt is precipitated unchanged by a slight excess of ammonia water. From another portion ammonium molybdate T.S. precipitates yellow ammonium phosphomolybdate; the reaction is accelerated by a gentle heat. If to 5 Cc. of the solution, acidulated with nitric acid, 0.5 Cc. of silver nitrate T.S. be added, not more than a slight turbidity should result (limit of chloride). The clear solution should not be rendered turbid by barium chloride T.S. (absence of sulphate); nor by potassium sulphate T.S. (barium); nor by an equal volume of hydrogen sulphide T.S. (arsenic, lead, etc.); nor should it be colored blue by potassium ferrocyanide T.S. (iron). If 5 Cc. of the solution be mixed with 1 Cc. of sodium acetate T.S., and then with ammonium oxalate T.S., until the calcium is completely precipitated, the filtrate should not be rendered very turbid by adding ammonia water in slight excess (limit of magnesium)"—(U. S. P.). Prolonged boiling with water slowly decomposes it, forming a soluble acid phosphate, and an insoluble basic phosphate of calcium ($\text{Ca}_3[\text{PO}_4]_2\text{OH}$).

Action, Medical Uses, and Dosage.—Phosphate of calcium was at one time considered a useful remedy in *rickets* and *mollities ossium*, its application to these diseases being based upon a theoretical inference from the state of the bones, which are known to be deficient in their calcareous constituents. Later it was presented to the profession as a remedy in the treatment of *tuberculous affections*, as *scrofula*, *pulmonary consumption*, etc. But it is extremely doubtful whether the beneficial results following its use are due to it, or to the other agents with which it is usually associated, as cod-liver oil, preparations of iron, etc. The following compound has been recommended in *phthisis*, *scrofula*, *chloro-anemia*, *mollities ossium*, *caries*, and *oxaluric gravel*: Take of precipitated phosphate of calcium, 30 parts; precipitated carbonate of calcium, 20 parts; bicarbonate of sodium, 6 parts; mix thoroughly together. The dose is 1 or 2 drachms in sweetened water, every morning and evening. Recently, some of our practitioners, basing their views partially upon homeopathic uses of the drug, have declared it a valuable remedy for that form of *malnutrition* in which the teeth, bones, connective tissue, and blood corpuscles suffer. *Rachitis*, *tardy union in fractures*, *ulcers* and *abscesses* of a *scrofulous* character, with rapid melting away of soft structures, exhaustive discharges, as *colliquative sweats of debility*, *leucorrhœa*, *bronchorrhœa*, *malnutrition during dentition*, *marasmus* following *cholera infantum* and *anemic conditions* are those in which it has been successfully used. In *chronic tonsillar* and *faucial irritation* in *scrofulous* patients, malnutritive states following child-bearing and suckling, and in *menstrual derangements* with debility and exhausting discharges, it has been highly commended. Small doses (1 or 2 grains), of the crude salt, or the triturations, may be employed. Some prefer the 3 x trituration. Dose of precipitated phosphate of calcium, 1 to 30 grains.

Specific Indications and Uses.—Strumous diathesis; profuse discharges, leucorrhœa, and profuse menstruation; debility after child-bearing; colliquative sweats, hectic fever; anemia; osteal and dental malnutrition.

Preparations and Related Bodies.—**SYRUPUS CALCI PHOSPHATIS**, *Syrup of phosphate of calcium*. Precipitated phosphate of calcium, 1 troy ounce; phosphoric acid, a sufficient quantity to dissolve the calcium salt without having an excess of the acid. Add simple syrup to make 1 pint of the finished product. Hydrochloric acid has been employed as a solvent, but phosphoric acid is better for this preparation.

Os.—*Bone*. The bones of the vertebrate animals consist of a compact organic tissue, impregnated with calcareous depositions. When fresh they are pinkish-white; when dried, a dull, ivory white. Water does not, but acids partially dissolve them, taking up the inorganic constituents, and leaving behind a gelatinous framework, called *ossein*. On the other hand, when calcined in the open air, the organic portion is totally destroyed, leaving a white, porous residue of inorganic matter. When heated in closed vessels by destructive distillation, a porous charcoal—*carbo animalis*—is produced, while ammoniacal products are given off. The organic constituent, *ossein*, when long boiled, yields gelatin. Bones of different species, different bones of the same animal, and different portions of the same bone, vary in the proportion of inorganic matter. The outer or *compact tissue* of bone contains the most, sometimes as high as 66 per cent; the inner or *cancellous tissue*, contains the least, sometimes as much as 40 per cent. Eby, in 1874, advanced the theory that the chief inorganic constituents of bone were combined with a chemical salt of the structure, $3\text{Ca}_3(\text{PO}_4)_2\text{CaCO}_3$, and probably with water,

and mixed with carbonate of calcium. The ash of bone is recognized in the *British Pharmacopœia* as *Ossis ustum* or *Bone ash*, and defined as "the residue of bones which have been burned to a white ash in contact with air. Bone consists principally of phosphate of calcium mixed with about 10 per cent of carbonate of calcium, and a little fluoride of calcium, silica, and phosphate of magnesium" (*Br. Ph.*). *Bone ash* or *bone earth* is employed chiefly in the preparation of calcium and sodium phosphates, glacial phosphoric acid, and phosphorus. *Bone ash* contains approximately traces of iron, silica, manganese, and sodium chloride, and less than 1 per cent of calcium fluoride, 1 to 2.7 per cent of magnesium phosphate, 5 to 10 per cent of calcium carbonate, and 75 per cent of calcium phosphate (the chief constituent). One hundred parts of ox bones (dry), 3.45 parts of soda with a small portion of sodium chloride, 2.05 parts of magnesium phosphate, 3.85 parts of calcium carbonate, 57.35 parts of calcium phosphate, with a little of calcium fluoride, and 33.3 parts of bone gelatin, the organic constituent (Berzelius). Gelatin, size, and glue are obtained from the organic constituent of bones. Animal jellies, isinglass, etc., are prepared from them. The hoof-bones of cattle yield the oil known as *neal's-foot oil* (*Oleum bubulum*).

SUPERPHOSPHATE OF LIME is extensively employed as a fertilizer. It contains organic matter, a small amount of magnesium compounds, acid calcium phosphate ($\text{Ca}[\text{H}_2\text{PO}_4]_2$) (22 or 23 per cent), and calcium sulphate (about 50 per cent). It is prepared by treating ground bones with about 50 per cent, by weight, of sulphuric acid. Such a mixture is employed also to extract ammonia from illuminating gas, forming besides the superphosphate of lime, a portion of phosphate and sulphate of ammonium, very valuable as an artificial manure.

CALCIUM SULPHAS EXSICCATUS (U. S. P.)—DRIED CALCIUM SULPHATE.

"A powder containing about 95 per cent, by weight, of calcium sulphate ($\text{CaSO}_4=135.73$), and about 5 per cent of water; prepared from the purer varieties of native gypsum ($\text{CaSO}_4+2\text{H}_2\text{O}=171.65$), by carefully heating until about $\frac{2}{3}$ of the water has been expelled. Dried calcium sulphate should be kept in well-closed vessels, carefully protected from moisture"—(*U. S. P.*).

SYNONYMS: *Plaster of Paris*, *Dried gypsum*, *Calcii sulphas* (*Br.*).

Description and Tests.—Plaster of Paris is "a fine white powder, without odor or taste. From moist air it attracts water, becomes granular, and then loses the property of hardening with water. When mixed with half of its weight of water, dried calcium sulphate forms a smooth, cohesive paste, which rapidly hardens. It is soluble in about 410 parts of water, at 15°C . (59°F .); in 388 parts, at 38°C . (100.4°F .); and in 476 parts, at 100°C . (212°F .). In alcohol it is insoluble. It readily dissolves in diluted nitric or hydrochloric acid, also in saturated solutions of potassium nitrate, sodium hyposulphite, and of various ammonium salts. When heated above 204°C . (399.2°F .), dried calcium sulphate becomes anhydrous and loses the property of forming a paste with water and hardening rapidly. Its saturated solution in water should be neutral to litmus paper. It forms white precipitates with barium chloride T.S., with ammonium oxalate T.S., and with alcohol. No effervescence should occur on the addition of diluted acids to dried calcium sulphate (absence of carbonate)"—(*U. S. P.*). Plaster of Paris hardens without decrease of bulk.

Surgical and Other Uses.—Plaster of Paris is chiefly used as an immovable *surgical dressing*, and as a material for preparing plaster casts as well as molds for the same and wax figures. The method is as follows: Into a common paste-board box of sufficient depth and size, pour a quantity of plaster of Paris, mixed with water, to the consistence of a soft magma, so that it will not run, but receive the impression of the article of which a mold is desired, and thick enough to quickly "set." Now, take the article, an apple for instance, grease it well and press it down to that portion of the model at which the dimensions begin to diminish. Allow the plaster to harden, and, without removing the apple, cut a conical depression, one on each side, into the plaster surface, a little distance from the apple, and again apply grease to the exposed portion of the fruit and to all of the exposed surface of the plaster, including the depression. Now, fill the box completely with more plaster of the same consistence as that first employed, completely burying the apple. Allow the mass to harden, when the two halves of the mold will readily come apart, and the fruit may be removed. The cut depressions in the lower half will have received plaster in the form of pegs depending from the upper half, and these will serve to accurately fit the parts of the mold

together when in use. Now cut a gutter in one-half of the mold, or in both opposed to each other, and the instrument is finished. To reproduce the figure, instrument, etc., in wax, all that is necessary is to bring the wax to a fluid state by heat and pour through the gutter a small quantity into the mold (previously thoroughly greasing inside), and then slowly revolve the mold until the wax has hardened. Separate the mold and remove the figure. To reproduce in plaster follow the same procedure, using a milk of plaster of Paris; if the figure is desired solid fill the mold full.

This process may be used to reproduce the shapes of instruments, surgical deformities, injuries, etc., but in order to obtain a mold of a part of the body, the hair must first be shaven from the part else much pain will be experienced in removing the mold from the flesh.

Plaster of Paris is the substance used in preparing the fixed surgical appliance known as the *plaster of Paris dressing*. To do this, take a roller of soft, coarse-meshed cloth—cheese-cloth, crinoline, flannel, or muslin, the latter is preferred—and rub into the meshes dry plaster and roll the bandage tightly. These may be used at once, or kept in air-tight, dry boxes until needed. To use these pour upon each end of the roller some cold water, or immerse the roller in the water. First apply a dry cloth without plaster and follow with the moistened plaster-impregnated bandage, being careful not to execute any reverses in applying the roller. It dries quickly and forms a light, hard dressing. When applied to the body it may be cut longitudinally and eyelets inserted, so as to serve as a *plaster jacket*. Plaster dressings are applied to *fractured limbs and ribs*, and certain *spinal deformities*. Many object to them on account of their concealing the injury and the liability of shortening, strangulation, and other accidents which may result from their unskillful application.

Related Compound.—CALCH SULPHAS. *Gypsum, Native calcium sulphate*.—This compound occurs in nature in the form of transparent prismatic bodies, known as *selenite*, or as white, somewhat opaque masses, termed *alabaster*. Gypsum is often beautifully colored by impurities present. Another beautiful modification is known as *satinspar*, or *fibrous gypsum*, from which many ornaments may be made. Ground gypsum, popularly known in rural sections as “land plaster, or plaster,” is used extensively in agriculture to spread upon the soil, and as a medium (or diluent) by which paris green may be applied to potato plants for the destruction of the Colorado beetle. It may be artificially prepared by precipitating calcium compounds with a sulphate, or with sulphuric acid. In this way it occurs as a crystalline, white powder, sparingly soluble in hot water, and more soluble in cold water. It refuses to dissolve in alcohol. But very little use has been made, in our school, of calcium sulphate as an internal remedy. Webster, however, following Schuessler, of “tissue-remedy” fame, states that it is a remedy closely allied to calcium sulphide, as a remedial agent in *suppurative states* of the connective tissues. It has been used in a variety of troubles, mainly of a scrofulous suppurative nature, much after the method of using calcium sulphide. Five grains of the 3x trituration is added to 4 fluid ounces of water, and teaspoonful doses administered every 2 hours in acute, and every 4 hours in chronic disorders. The preparation used by Homœopaths is that prepared by acting upon solution of calcium chloride with diluted sulphuric acid, washing the precipitate with hot water, and drying the product at a heat near 30° C. (86° F.).—(*Am. Hom. Pharm.*).

CALCH SULPHIS.—CALCIUM SULPHITE.

FORMULA (of anhydrous salt): CaSO_3 . MOLECULAR WEIGHT: 119.76.

FORMULA (of crystallized salt): $\text{CaSO}_3 + 2\text{H}_2\text{O}$. MOLECULAR WEIGHT: 155.68.

Preparation.—Sulphite of calcium may be made by mixing a solution of a normal sulphite with a solution of a salt of calcium. Also, by making a thick paste with slaked lime and water, spreading in thin layers, and passing sulphurous acid gas over it until absorption of the gas ceases. The latter is the process employed on a large scale.

Description.—This salt is a white powder of a weak, sulphurous taste, and is known in commerce as *sulphite of lime*. It is soluble in 800 parts of water, and freely soluble in solution of sulphurous acid, without effervescence. If effervescence ensues, carbonate of calcium is present as an impurity. When the solution in sulphurous acid is exposed to the atmosphere, the acid escapes, and 6-sided needles of the composition $\text{CaSO}_3 + 2\text{H}_2\text{O}$ separate. Sulphite of calcium is chiefly consumed by cider-makers, as the addition of a small amount will retard or check

the vinous fermentation. For this purpose it has been customary to permit fermentation to progress until the cider is of the desired quality, then to add to it sulphite of calcium in the proportion of 4 or 6 ounces to the cask of 40 gallons of cider, then agitate well, permit the turbid liquid to settle, and afterward, as desired, draw off the clear cider. The impurities that may be expected to exist in sulphite of calcium are such as are contained in the lime from which it is prepared, as, carbonate of calcium from previous exposure of the slacked lime to atmospheric action, and sulphate of calcium, both in varying proportions. The latter substance is gradually produced when sulphite of calcium is exposed to the atmosphere.

Action, Medical Uses, and Dosage.—Sulphite of calcium and "bisulphite of lime" (see below), possess properties similar to other sulphurous acid preparations, being disinfectant and antiseptic. They are mostly employed for the purpose of checking fermentation in fluids liable to undergo such action. They are rarely employed in medicine, except, occasionally, to disinfect and stimulate *obstinate ulcers* of long standing. For internal use, there are several other sulphites before the profession that are preferred. Dose, 5 to 60 grains.

Related Compound.—BISULPHITE OF LIME. The solution of sulphite of calcium in sulphurous acid water is known in commerce as *bisulphite of lime*, and is produced by passing sulphurous acid into milk of lime. It is a clear liquid of a suffocating sulphurous odor, and is said to be used by brewers for the purpose of giving stability to beer (Roscoe and Schorlemmer), and is occasionally employed by fruit preservers, in small proportion, for the purpose of preventing fermentation in canned fruit. It is useful for preserving anatomical specimens and animal tissues of several kinds. It is also considerably employed to prevent fermentation in cider, wine, etc.

CALENDULA (U. S. P.)—CALENDULA.

The florets and leaves of *Calendula officinalis*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Calendula*, *Marigold*, *Marygold*, *Garden marigold*.

Botanical Source.—*Calendula officinalis* has a fibrous, annual root, with a stem about a foot high, having many patent, dichotomous, or sometimes trichotomous branches, which are striated, green, succulent, and hispidopubescent. The leaves are alternate, oblong, acute, mucronate, sessile, somewhat succulent, broad, a little cordate at the base, the margins quite entire, often scabrous-ciliate. The flower-heads are large, terminal, solitary upon each branch, of a rich, full, golden yellow, deeper and brighter previous to their full expansion. The involucre consists of many nearly equal, appressed, linear-subulate, pilose-hispid leaves or scales, not one-third as long as the radiant florets, the apices a little recurved. Achenia carinate, muricate, incurved. Corollas of the ray ligulate, female tridentate, broadly linear, lower tubular portion hairy; ovary singularly boat-shaped, curved like a horse-shoe, large, green, downy within, having a thickened margin, more or less tuberculated on the back. The florets of the center are all tubular, small, male, and consequently sterile; mouth 5-cleft, base hairy. The abortive ovaries are cylindrical, downy, and green. Receptacle dotted (L.—W.).

History.—*Calendula* is a native of South Europe and the Orient. It is a common garden herb, with a feeble, aromatic, somewhat narcotic, though not very unpleasant smell, and a salty, austere, rather disagreeable taste. The leaves, and more generally the flowers are used, and impart their active properties to alcohol or boiling water. The dried plant has a much weaker odor and taste. The dried flower heads are occasionally found in commerce. The *French* and the *African marigold* of our gardens, *Tagetes erecta*, Linné, and *Tagetes patula*, Linné, respectively, natives of the tropics, have been sold for true *calendula*, and it is believed that much of the fluid preparations of *calendula* are prepared from these plants.

Description.—"Florets about 12 Mm. ($\frac{1}{2}$ inch) long, linear and strap-shaped, delicately veined in a longitudinal direction, yellow or orange-colored, 3-toothed above, the short, hairy tube enclosing the remnants of a filiform style, terminating in 2 elongated branches; odor slight and somewhat heavy; taste somewhat bitter and faintly saline"—(U. S. P.).

Chemical Composition.—Geiger, who examined this plant in 1819, found gum, sugar, an amorphous, bitter body, a minute quantity of volatile oil, and a tasteless, yellow substance to which the name *calendulin* was applied. *Calendulin* is obtained by digesting the flowers and leaves of marigold in alcohol, and then evaporating the solution to the consistence of an extract. This must first be digested in ether, which dissolves a substance analogous to wax, and afterward in water. The mucilaginous substance which remains is the calendulin. It is, when dried, yellowish, translucent, and brittle; it swells up and forms mucilage with water; it dissolves in hot water, but assumes the form of jelly on cooling. It is insoluble in the diluted acids, alkaline carbonates, lime, ether, and the fixed and volatile oils, and soluble in concentrated acetic acid, diluted solutions of the caustic alkalis, and in absolute alcohol. It is not precipitated by tannin.

Action, Medical Uses, and Dosage.—Slightly stimulant and diaphoretic. Used for similar purposes with saffron, but less active. Has been reputed useful in *spasmodic affections, strumous maladies, icterus, suppressed menstruation, typhoid febrile conditions, cancer*, etc. Used in infusion or in the form of extract, from 4 to 6 grains, 3 or 4 times a day; also applied locally to *cancerous* and other *ulcers*. Probably overestimated. Its chief use is as a local remedy. Dr. William J. Clary, of Monroeville, Ohio, writes me as follows, in relation to this plant: "As a local remedy after surgical operations, it has no equal in *Materia Medica*. Its *forte* is its influence on *lacerated wounds*, without regard to the general health of the patient or the weather. If applied constantly, gangrene will not follow, and, I might say, there will be but little, if any, danger of tetanus. When applied to a wound it is seldom that any suppuration follows, the wound healing by replacement or first intention. It has been tested by several practitioners, and by one, is used after every surgical operation with the happiest effect. You need not fear to use it in wounds, and I would not be without it for a hundred times its cost. It is to be made into a saturated tincture with whiskey diluted with one-third its quantity of water; lint is saturated with this, applied to the parts, and renewed as often as it becomes dry."

The statement of Dr. Clary has stood the test of time, and now hundreds of advocates of calendula endorse it. It may be used well diluted for the *chafing* and *excoriations* of infants. Michener (*Cal. Med. Jour.*), claims remarkable results from its use in *gangrenous* and *indolent ulcers* with capillary impairment. Use 1 part of specific calendula to 3 parts of water, locally, keeping the parts constantly wet. Teaspoonful doses every 4 hours of a solution of specific calendula flj, in water flziv, are to be given at the same time. He also uses it successfully after *surgical operations* to induce healing by first intention, to wash *abscess cavities*, to prevent cicatrization from *burns* and *scalds*, in *eczematous* and *ulcerative skin diseases*, *vaginitis* (wash or tampon), *endocervicitis*, *gonorrhœa*, *non-specific urethritis*, and *mercurial stomatitis*. Dr. Bradner (*An. of Ec. Med.*, 1890), states that cavities from which *epitheliomatous growths* have been removed, heal quickly under the use of the evaporated fluid extract mixed with petrolatum. Locally, by atomizer, the doctor directs: R Tr. calendula, gtt. x to lx; ol. petrolatum, zi. Mix. In *catarrhal conditions* of the nose and throat, with raw and tender membranes, its action is kindly and soothing. Lamoreaux (*An. of Ec. Med.*, 1890), uses it in mild *conjunctivitis* in the proportion of 5 drops to the ounce of rose water; and as a dressing for *lacerated perineum* he states that it operates to prevent pain and swelling. In obstetric practice it is of value to relieve burning and smarting after delivery, and relieves to some extent the pain and tenderness of *excoriated nipples*. In *vaginitis*, *endometritis*, all *uterine* and *vaginal abrasions*, and *non-malignant ulcerations*, *leucorrhœa*, and as an intra-uterine wash, calendula has received strong endorsement. It is a vaso-motor stimulant, and relieves capillary engorgement of the mucous tissues and skin. Congestion of the nasal membranes and its consequent unpleasantness are removed by it. *Uterine subinvolution* and *vaginal engorgements* are thus relieved. It stimulates *ecchymosed tissues*, and has been recommended in *varicose* of the lower limbs, using it both locally and internally. Locally, it is applied diluted to inflamed conjunctival and aural tissues, and to *traumatic injuries of the eye and ear*. Foltz (*Dynam. Ther.*) employs it in *suppurative otitis media* as follows: R Specific calendula, flj; boric acid, flj. Mix. Ft. chart, No. 1. Use by insufflation. Prof. Webster values it in *superficial skin affections*, even where there are long-standing

inflammatory indurations, as in stubborn *acne*. Use it both locally and internally. Locally, specific calendula (the best form), from 1 to 4 parts of water to full strength; internally in doses 1 to 10 drops.

Specific Indications and Uses.—Locally, to wounds and injuries to prevent suppuration and promote rapid healing. Internally, to aid local action, and in chronic suppuration, capillary engorgement, varicose veins, old ulcers, splenic and hepatic congestion.

Related Species.—*Calendula arvensis*, Linné. A cultivated species, smaller than the preceding, and having lighter-colored flowers, undoubtedly having properties similar to those of the foregoing species, its taste and odor being similar.

CALLITRICHE.—WATER-STARWORT.

The whole plant, *Callitriche verna*, Linné.

Nat. Ord.—Callitrichaceæ.

COMMON NAMES: *Water-starwort*, *Water-chickweed*.

Botanical Source.—This plant is a small aquatic annual herb, which floats upon the water, the stem being 1 or 2 feet in length, and composed of 2 tubes, simple or branched. The leaves are opposite, 3-nerved; upper ones oblong-spatulate, two at each node, crowded above into a star-like tuft upon the surface of the water; lower ones becoming gradually narrower, the lowest quite linear, obtuse or emarginate. The flowers are very minute, white, axillary, solitary, or in pairs, and often monœcious; the anther is a little exserted and yellow; the styles constantly erect; the fruit nut-like, indehiscent, 1-celled, and 4-seeded; the seeds peltate and albuminous (W.).

History.—This plant is common to the United States, growing in shallow streams and muddy places, and flowering from April to September. The whole plant is used; it yields its properties to water, or alcohol. There are several varieties, as *C. autumnalis*, *C. arvensis*, *C. heterophylla*, all of which possess similar medicinal virtues.

Action, Medical Uses, and Dosage.—This plant is a very valuable diuretic, and has been found advantageous in some affections of the kidneys and bladder, *dropsy*, and *gonorrhœa*. A decoction of it may be drank freely, according to its diuretic influence. In dropsy, a tincture made with whiskey is preferred. The plant deserves more attention than it has heretofore received.

CALUMBA (U. S. P.)—CALUMBA.

"The root of *Jateorhiza palmata* (Lamarek), Miers"—(U. S. P.) (*Cocculus palmatus*, Wallich).

Nat. Ord.—Menispermaceæ.

COMMON NAMES: *Colombo*, *Colombo*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 13.

Botanical Source.—Colombo is a climbing plant, with a perennial root, formed of a number of fasciculated, fusiform, somewhat branched, fleshy, curved, descending tubers, of the thickness of an infant's arm, covered with a thin, brown epidermis, marked, especially toward the upper part, with transverse warts; internally they are deep yellow, inodorous, very bitter, filled with numerous, parallel, longitudinal fibers, or vessels. The stems, of which 1 or 2 proceed from the same root, are annual, herbaceous, about as thick as the little finger, simple in the male plant, twining, branched in the female, rounded and green; in the full-grown plant, below, they are thickly clothed with succulent, longitudinal hairs, which are tipped with a gland. The leaves are alternate and large; the younger ones thin, pellucid, bright-green, generally 3-lobed, and upward gradually more numerous; the older ones remote, a span in breadth, nearly orbicular, deeply cordate, 5 to 7-lobed, the lobes entire, often deflexed, wavy on the surface and margin, dark-green above, paler beneath; hairy on both sides; the nerves, according to the number of lobes, are 3, 7, or 9, pale, connected by veins which, in themselves, are reticulated and are prominent beneath. The petioles are about as long as the

leaves, rounded, glanduloso-pilose, and thickened below. The flowers are small, indistinct, arranged in the male plant in solitary, axillary, drooping, compound racemes, covered with glandular hairs, and with small, caducous bracts at the base; in the female they are also axillary, solitary, simple, spreading, but shorter than those of the male. Sepals 6, glabrous; petals 6, in a single row; stamens 6; anthers terminal and 4-celled. The fruit is drupaceous, or berried, about the size of a hazel-nut, densely clothed with long, spreading hairs, and tipped with a black, oblong gland. The seeds are black, striated transversely, and subreniform (L.).

History.—This plant inhabits the forests near the coast of Mozambique, and Oibo in East Africa, and has been cultivated at Madras, and in the Isle of France. It was formerly incorrectly described as *Menispermum palmatum*, and has more recently been properly investigated and classified. It grows abundantly on the southeastern coast of Africa, where in the neighborhood of Mozambique, it is known by the name *Kulumb*. The root is dug up in the dry season in the month of March, and is very fibrous and ligneous, only its spindle-shaped offsets are removed, being cut in slices, strung on cords, and hung up to dry in the shade.

Description.—As met with in commerce, Colombo root consists of transverse sections from $\frac{1}{2}$ an inch to 3 inches in diameter, and from 1 to 8 or 10 lines thick. These sections are composed of a thin, olive-brown and generally rugose cuticle; a thick, bright-yellow, easily detached inner bark; and a pith or spongy ligneous internal structure of a pale-brown or yellowish color, more or less contracted, often exhibiting dark concentric rings with radiated striae. The best pieces are those which are firm, dense, and regular, of a lively color, and not much injured by insects. The root is friable and readily reduced to a pale greenish-yellow powder, having a faintly aromatic odor, and an unpleasant, bitter taste, without the slightest acrimony or astringency. Alcohol, or boiling water, extracts its virtues. The bark has the strongest taste, which is readily taken up by water, alcohol, or ether. The central pith is almost mucilaginous. The powder soon spoils and becomes unfit for use, in consequence of absorbing moisture from a damp atmosphere. It is better to powder the root in limited portions, when required, keeping the powder in closely-stoppered bottles (P.). The U. S. P. describes it as "in nearly circular disks, 3 to 6 Cm. ($1\frac{1}{4}$ to $2\frac{1}{4}$ inches) in diameter, externally greenish-brown and wrinkled, internally yellowish, or grayish-yellow, depressed in the center, with a few interrupted circles of projecting wood-bundles, distinctly radiate in the outer portion; fracture short, mealy; odor slight; taste mucilaginous, slightly aromatic, very bitter"—(U. S. P.).

Adulterations.—The American Colombo (*Fraseria Walteri*, Michaux), which is sometimes added to the genuine article, contains no starch, and is not, therefore, affected by iodine; but it contains tannic acid, and, therefore, becomes blackish-green when sulphate of iron is added to its decoction, and yields a precipitate with a solution of gelatin (P.). White bryony (*Bryonia alba*) root is said to have been an adulterant also. Both this and American Colombo root can be detected by their widely divergent physical characteristics, so different from Calumba. A wood, known as *false Colombo*, or *Colombo wood* (from *Cascinum fenestratum*), also of the Moonseed family, has been received into England from Ceylon.

Chemical Composition.—According to Planche and Buchner, the root contains bitter matter, yellow resinous extractive, volatile oil, wax, gum, starch, vegetable medulla, woody fiber, and water. Wittstock, in 1830, discovered a bitter principle, which he named *colombin*, or *columbin*. If the genuine Colombo be first moistened, it does not become black when in contact with tincture of iron; iodine added to a decoction of the root, forms the blue iodide of starch; a decoction of the root does not redden litmus paper, nor is there any precipitate (tannic and gallic acids) when tartar emetic, gelatin, or sulphate or perchloride of iron are added to it; infusion of nut-galls, or tannic acid cause a precipitate.

Columbin ($C_{24}H_{40}O_{14}$) may be obtained by treating Colombo root twice or thrice successively with alcohol of specific gravity 0.835. Mix these solutions, distill off $\frac{2}{3}$ of the alcohol, and allow the residual liquid to remain at rest for some days. Crystals are deposited which may be collected by throwing the whole on a cloth and allowing the liquid portion to pass. These crystals are to be washed in cold water, dissolved in alcohol, and the solution digested with ivory-black, and filtered. When the solution thus treated is concentrated, it deposits pure crystals

of columbin. The mother liquor still contains abundance of the same principle, which may be separated by mixing it with powdered glass and evaporating to dryness, stirring it constantly when it begins to become concrete. Digest this mixture of powder and glass in ether, which dissolves wax, fatty matter and columbin. Distill off the ether, digest the residue in boiling acetic acid, which takes up only the columbin, then evaporate, and crystals are formed. Sixty grains are obtained from $\frac{1}{2}$ pound of the root. Columbin crystallizes in transparent rhombic prisms, which are inodorous, but very bitter. They are neutral, little soluble in water, alcohol, or ether, at ordinary temperatures, yet give a bitter taste, to them; boiling alcohol dissolves from $\frac{1}{10}$ to $\frac{1}{5}$ of its weight, but on cooling deposits them. Volatile oils sparingly dissolve them. The caustic alkalies dissolve columbin, from which it is precipitated unaltered by acids; nitric and sulphuric acids dissolve it, but hydrochloric acid has very little action on it. Boiling acetic acid of specific gravity 1.04, is its best solvent (T.).

Berberine ($C_{22}H_{17}NO_4$) exists in colombo root to a large extent, being in union with *columbic acid*. Dr. Bodeker obtained it by exhausting the colombo root with boiling alcohol of specific gravity 0.889, removing as much of the alcohol as possible by distillation; and when a yellowish-brown mass of impure columbin had separated after 3 days' standing, the supernatant liquid, together with the aqueous solution arising from the rinsing of the impure columbin, was evaporated to dryness on a water-bath. The residue was exhausted with boiling alcohol of specific gravity 0.863, and this solution again treated as the preceding one. The residue was then treated with boiling water, and the filtered solution mixed with a considerable quantity of hydrochloric acid. The precipitate thus formed was collected on a filter, and well pressed between paper. Owing to its great solubility in pure water and alcohol, it could not be washed. To remove any free adherent acid, it was dissolved in alcohol of 0.863, and precipitated from this solution by ether. The salt obtained was an indistinctly crystalline bright-yellow powder, of an unpleasant bitter taste, and believed to be the hydrochlorate of berberine (*Amer. Jour. Pharm.*, Vol. XX., p. 322). We have not verified these experiments, but, in our opinion, if the resultant salt is, as stated, very soluble in water, it is *not* hydrochlorate of berberine. *Columbic acid* ($C_{22}H_{17}O_7$) is amorphous, but sparingly soluble in water (cold), but dissolves in diluted alkalies and alcohol, is of a pale-yellow color, and bitter to the taste.

Columbine, a white body, has been obtained by Alessandri (1882), who believes it to be an alkaloid. It was prepared by neutralizing an infusion of calumba made with oxalic acid solution (3 per cent) and evaporated to one-third, cooled, ether added, and the solution again evaporated, when pure columbine remains—(*L'Orosi*, Vol. I; *P. J. Tr.*, 1882, p. 995).

Action, Medical Uses, and Dosage.—A pure, bitter tonic, which neither stimulates nor astringes. It acts upon the stomach much like *hydrastis*. Used in *dyspepsia*, *chronic diarrhoea*, and *dysentery*; in convalescence from *febrile* and *inflammatory diseases*, *hectic fever*, *dysentery* and *diarrhoea*; and in the *muscular debility* of young children. It has been efficient in *sympathetic vomiting*, not connected with gastritis, as in *pregnancy*. Like other strong bitters, it occasionally checks the *remittent* and *intermittent fevers* of hot climates. A powerful tonic may be formed of the alcoholic extract of the root. In *dyspepsia* and *vomiting*, it may be advantageously combined with the alkaline bicarbonates, as well as in debility with acidity of the stomach. It is used in various combinations, with aromatics, antacids, cathartics, or other tonics. It is particularly useful in *dyspepsia*, with constipation and hepatic torpor, and should be employed in 5-drop doses of specific calumba associated with a light dose of specific rheum or leptandra, to be given 5 or 6 times a day. In *cholera morbus* it stops the vomiting and purging, and imparts strength; after the active phases of *cholera infantum*, when an unirritating tonic is desired, this agent is to be preferred. Dose of the powder, from 10 to 30 grains, 3 or 4 times a day; of the infusion, from 1 to 2 fluid ounces; of the tincture, from 1 to 2 fluid drachms; of specific calumba, 5 to 30 drops, 3 to 5 times a day. Colombin is highly useful in the treatment of *dyspepsia*, in doses of from $\frac{1}{4}$ of a grain to $2\frac{1}{2}$ grains daily.

Specific Indications and Uses.—Enfeebled stomach, with indigestion, or feeble digestion; anorexia, and general debility.

CALX (U. S. P.)—LIME.

FORMULA: CaO . **MOLECULAR WEIGHT:** 55.87.

"Lime prepared by burning white marble, oyster shells, or the purest varieties of natural calcium carbonate. It should be kept in well-closed vessels, in a dry place"—(U. S. P.).

SYNONYMS: *Calcium monoxide, Caustic lime, Quicklime, Calcii oxidum, Calcaria, Calx usta, Calx viva, Burned lime, Oxydum calcicum.*

Source and Preparation.—Lime does not exist in the pure or caustic state in nature, because if exposed in this condition it would rapidly absorb carbonic acid gas. It is prepared by heating a natural carbonate of calcium, by which process its carbonic acid gas is set free, while the lime is left in the residue. It is found purest in limestone, chalk, marble, and the shells of oysters. That procured from the last two is quite pure and especially suited for the delicate investigations in the chemical laboratory. The Edinburgh College ordered white marble, broken into small fragments, to be heated "in a covered crucible at a full red heat for 3 hours, or till the residuum, when slaked and suspended in water, no longer effervesces on the addition of hydrochloric acid." After the lime has become cool, it should be at once secured in well-closed vessels, to prevent it from absorbing carbonic acid gas from the atmosphere, which it does very speedily. This gives a very pure product. The burning of the limestone on a large scale is conducted in *lime-kilns* in such a manner that a good draught of air passes through the heated lime-stones. The chemical reaction involved is as follows: $\text{CaCO}_3 = \text{CaO} + \text{CO}_2$. If not conducted with a good draught the liberated carbonic acid gas would surround the limestones and prevent them, even at a high heat, from parting with the remaining carbon dioxide. As ordinarily prepared it contains a large amount of impurities, notably ferric oxide, magnesia, alkaline compounds, clay, and silica. The presence of much clay causes it to slack slowly and feebly, or scarcely at all, the cause being the formation of a glaze of calcium silicate, which obstructs the free access of water, and when this is the case it is commonly called "*poor lime*" or "*over-burnt lime*." It may be obtained pure by calcining pure carbonate of calcium in a crucible, moistening the resulting product, and recalcining, by means of which the carbon dioxide will be completely dissipated.

Description and Tests.—The U. S. P. describes lime as "hard, white, or grayish-white masses, which, in contact with air, gradually attract moisture and carbon dioxide, and fall to a white powder; odorless, of a sharp, caustic taste. Soluble in about 750 parts of water at 15° C. (59° F.), and in about 1300 parts of boiling water; insoluble in alcohol. Soluble in diluted acetic, hydrochloric, or nitric acid. When sprinkled with about half its weight of water, lime becomes heated, and is gradually converted into a white powder (calcium hydrate or slaked lime). When this is mixed with about 3 or 4 parts of water, it forms a uniform, smooth magma (milk of lime). Even at the highest degrees of heat, lime remains unaltered and does not fuse. Its aqueous solution gives an intensely alkaline reaction with litmus paper"—(U. S. P.).

Lime, when pure, is a white or grayish solid, moderately hard, but easily reduced to powder, and having a specific gravity of about 3.08. It has a hot, burning, alkaline taste, in some measure corrodes and destroys animal tissues, reacts powerfully on vegetable colors as an alkali, and is difficult of fusion, requiring the oxyhydrogen flame to both fuse and volatilize it. A pint of water at 0° C. (32° F.), dissolves 13.25 grains of lime; at 100° C. (212° F.), it dissolves only 6.7 grains. The dense fluid termed *milk of lime*, is slaked lime suspended in lime water. When water is added to lime, this swells up, cracks, and becomes reduced to powder, with the evolution of a considerable degree of heat; in this state it is called *slaked lime* (*calx extincta*), or the *hydrate of lime* (*calcis hydras*), *milk of lime* (*hydroxide of calcium*). It is white, pulverulent, much less caustic than lime, and is principally used for preparing chlorinated lime. On exposure to the air it falls to white powder known as "*air-slaked lime*." Its ashen-gray color is due to impurities present in the stone from which it is prepared. When perfectly pure it is a white compound. When heated in an oxyhydrogen flame it emits an intensely brilliant white light, and when the flame of the oxyhydrogen

blow-pipe is directed upon a small piece of quicklime the *oxy-hydrogen-calcium light* is produced, and when the oxygen gas is first passed through an alcohol lamp flame, a less brilliant light (the *oxy-calcium light*), is the result. These lights are used for stereopticon exhibitions and for theatrical stage-effects. Lime is one of the alkaline earths, differing from the others in forming an exceedingly deliquescent salt with chlorhydric acid (calcium chloride), and one practically insoluble with sulphuric acid (calcium sulphate).

In 1808, Davy showed that lime was an oxide of calcium. Lime is soluble in hydrochloric acid without effervescence, and the solution gives no precipitate with ammonia. Lime-water reddens yellow turmeric paper, turns infusion of red cabbage green, is rendered milky on the addition of carbon dioxide; forms a white precipitate with oxalic acid or an oxalate, and gives no precipitate with sulphuric acid. "It enters very readily into combination with all the acids, sulphur, and phosphorus, and decomposes the alkaline carbonates, phosphates, fluorides, borates, oxalates, tartrates, and citrates; the ammoniacal acetates, chlorides, and succinates, the sulphates of aluminum and magnesium; the metallic salts, spirituous liquors, and astringent substances" (Coxe). Consequently the above are incompatibles. "Its solution in diluted acetic acid gives, with ammonium oxalate T.S., a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If 1 part of lime be slaked and then thoroughly mixed with 50 parts of water, and the greater portion of the milky liquid decanted, no hard, gritty particles should be found in the residue, nor should the addition of hydrochloric acid to this residue cause much effervescence (limit of carbonate), nor leave more than a slight insoluble residue. If the decanted portion be dissolved in acetic acid and filtered if necessary, a portion of the filtrate should not be rendered turbid by potassium dichromate T.S. (absence of barium). In another portion of the filtrate, the addition of the ammonia water should not produce more than a slight turbidity (limit of aluminum, etc.)."—(U. S. P.).

Laboratory and Pharmaceutical Uses.—Lime is employed to dry gases and to abstract water from alcohol and ether when concentration free from moisture is desired. It forms, under certain conditions, insoluble salts with many acids, *e. g.*, carbonic, phosphoric, and citric acids; hence, it is useful, not only in the preparation of alkaline compounds, as, for example, caustic potash or soda, and alkaloidal products, and certain other principles (santonin, etc.), but also of organic acids (citric acid, tartaric acid, etc.). It is used in making precipitated sulphur (milk of sulphur); in preparing liquor calcis, potassium chlorate, and especially sodium carbonate according to Leblanc's process, and many other chemical materials.

Action and Medical Uses.—Unslaked lime disintegrates animal and vegetable tissues, favoring their solution, and with albumen forms a horn-like substance. Its use by tanners to remove cuticle and hair from hides is well known. It is not so energetic a caustic as the alkalis on account of the fact that it has not so great an affinity for water. Internally, it may act as a violent gastro-intestinal poison. Diluted acids will antidote it. For its internal employment, see *Liquor Calcis*. Externally it is a powerful escharotic. It is generally employed with other agents. *Potassa cum calce*, a powerful caustic for cauterizing the neck of the uterus, or other parts, and also known as *Vienna powder* or *paste*, is made by reducing caustic potash $1\frac{1}{2}$ ounces, and quicklime 2 ounces, each separately, to powder in a heated mortar; then mix them carefully and rapidly, and keep the mixture in a wide-mouthed bottle with a ground stopper. In using this caustic, the powder must be moistened with a little alcohol, so as to reduce it to a soft paste, which is to be applied to the part to be cauterized. In this case the potassa only acts upon a circumscribed portion of skin, instead of spreading, as common caustic potash generally does; but to bound the space still more accurately, it may be surrounded by a ring of diachylon plaster; vinegar will neutralize its action. This caustic is sometimes made with equal parts of the two articles forming it. It is also prepared in sticks. Dr. Filhos has prepared a caustic of the same agents, which is more easily used; it is called the *Caustic of Filhos*. It is made by fusing together 6 ounces of caustic potash, and 3 ounces of quicklime; the mixture is poured into leaden cylinders inclosed in glass tubes, and which are to be sealed afterward at each end. *London paste*, also used as a caustic for destroying

abnormal growths, is made by making a pasty mass with equal parts of caustic soda and unslaked lime, and a sufficient quantity of absolute alcohol; it should not be allowed to remain in contact with the parts more than 5 or 6 seconds. It has been especially recommended for the removal of *enlarged tonsils*.

In cases where diaphoresis is desirable, without disturbing the patient, it may be effected as follows: Take a piece of lime about the size of a Sicily orange, and wrap around it a wet rag, but not too wet; around this wrap several thicknesses of dry muslin or cloth. Place one thus prepared on each side of the patient, and by both thighs; it will soon induce copious perspiration.

Lime is freely used to *arrest putrefaction* in cesspools, slaughter-houses, dissecting rooms, drains, vaults, sewers, etc., and to disinfect the stools in infectious diseases.

Related Preparation.—*CALCI HYDRAS.* *Calcium hydroxide, Calcium hydrate, Slaked lime, Hydrate of lime, Calcaria hydrica.* Formula: $\text{Ca}(\text{OH})_2$. Molecular weight: 73.83. When lime is gradually treated with about one-third of its bulk of water it unites with it to form slaked lime under evolution of much heat. So intense is this heat that fires are said to have resulted from it. For the preparation of this compound the *British Pharmacopœia* directs 2 pounds of lime and 1 pint (Imp.) of distilled water. Introduce the lime into a metallic pot, pour upon it the water, and when vapors cease to arise, cover and set aside to cool. When reduced to the atmospheric temperature, transfer the slaked lime to a wire sieve, and gently agitate to allow the finer particles to pass, rejecting that which remains in the sieve. Keep the powder away from the air by putting it in closely-stoppered bottles. Slaked lime is a pure white powder, strongly alkaline in reaction and taste, and soluble in acids without much effervescence, if but little carbonate is present. A dull, red heat renders it perfectly anhydrous without previous fusion. On exposure to the atmosphere it absorbs carbon dioxide, and forms calcium carbonate. "One hundred parts of water at 15.6° C. (60° F.), dissolve 0.1368 parts, and at 100° C. (212° F.), only dissolve 0.0752 parts." Its solution is known as lime-water (see *Liquor Calcis*). When quicklime is slaked, or when slaked lime is made into a thin paste with 3 or 4 parts of water, it forms *milk of lime*, a preparation considerably employed in chemical manipulations, and as "*white wash*" for ceilings. For uses see *Liquor Calcis* (see also above).

CALX CHLORATA (U. S. P.)—CHLORINATED LIME.

"A compound resulting from the action of chlorine upon calcium hydrate, and containing not less than 35 per cent of available chlorine. This preparation is often improperly called 'chloride of lime.' Chlorinated lime should be kept in well-closed vessels, in a cool and dry place"—(U. S. P.).

SYNONYMS: *Chloride of lime, Bleaching powder, Hypochlorite of calcium, Calx chlorinata, Calcaria chlorata.*

Preparation.—This compound is made essentially on the same principle as when first prepared by Tennant and Knox at the close of the last century. It is prepared by passing thoroughly dried and perfectly slaked lime through a sieve, and spreading the powder so produced upon trays arranged tier upon tier, in proper chambers or boxes. Upon these trays a stream of chlorine gas is directed from the top until the slaked lime has absorbed all the gas it will take up. Care should be taken to prevent a temperature above 25° C (77° F.), so as to guard against the formation of chlorate of calcium ($\text{Ca}[\text{ClO}_3]_2$). It may be prepared so as to contain *available chlorine* (see below) to the amount of 43 per cent. The reaction involved is as follows: $\text{Ca}(\text{OH})_2 + \text{Cl}_2 = \text{Ca}(\text{ClO})_2 + \text{CaCl}_2 + 2\text{H}_2\text{O}$. The compound formed is looked upon by some as being a mixture of calcium hypochlorite and calcium chloride ($\text{Ca}[\text{ClO}]_2 + \text{CaCl}_2$), by others as being a definite compound, $\text{CaCl}(\text{OCl}) + \text{H}_2\text{O}$. The improvements in this process have consisted mainly in the introduction of new methods in the manufacture of the chlorine gas. Efforts are being made, for example, to obtain chlorine gas on a manufacturing scale by electrolysis of chloride of potassium or of the chlorides of heavy metals, such as zinc or copper. For an interesting historical résumé of the progress made in the manufacture of chlorine gas, see paper by L. Mond, read before the B. A. A. S., 1896 (*Pharm. Jour. Trans.*, 1896, p. 282).

Description and Tests.—The *Pharmacopœia* describes chlorinated lime as follows: "A white, or grayish-white, granular powder, exhaling the odor of hypochlorous acid, having a repulsive, saline taste, and becoming moist and gradually decomposing on exposure to air. In water or in alcohol it is only partially soluble. The aqueous solution first colors red litmus paper blue, and then bleaches it."

If the salt be dissolved in diluted acetic acid, an abundance of chlorine gas is evolved, and only a trifling residue left undissolved. From this solution ammonium oxalate T.S. throws down a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If 0.35 (0.354) Gm. of chlorinated lime be thoroughly triturated with 50 Cc. of water and carefully transferred, together with the washings, into a flask, and then 0.8 Gm. of potassium iodide and 5 Cc. of diluted hydrochloric acid added, the reddish-brown liquid, mixed, toward the end of the titration, with a few drops of starch T.S., should require for complete decoloration, not less than 35 Cc. of decinormal sodium hyposulphite V.S. (each cubic centimeter corresponding to 1 per cent of available chlorine)"—(U. S. P.).

Much of the commercial product contains from 20 to 35 per cent of available gas. Chlorinated lime decomposes even when preserved in close containers, and it is recorded that explosions have occurred when so secured. Even carbonic acid gas slowly decomposes this compound with the liberation of hypochlorous acid (ClOH). Oxygen is evolved from its solution in water when mixed with black oxide of manganese, and other oxides. It has active decolorizing properties. Excessive moisture indicates the presence of calcium chloride, and the amount of lime in excess may be approximately determined by its degree of solubility.

By the term *available chlorine*, is understood the amount of chlorine gas which is evolved by bringing chlorinated lime into contact with acids in excess, e. g., sulphuric acid, according to the following equation: $\text{CaOCl}_2 + \text{H}_2\text{O} + \text{H}_2\text{SO}_4 = \text{CaSO}_4 + 2\text{H}_2\text{O} + 2\text{Cl}$. Hydrochloric acid would effect a similar decomposition, the only difference consisting in the formation of calcium chloride instead of sulphate.

The amount of *available chlorine* in calx chlorata may be determined in various ways. By the U. S. P. process (see above), the available chlorine liberates iodine from potassium iodide in acid solution according to the equation: $2\text{KI} + \text{Cl}_2 = 2\text{KCl} + 2\text{I}$. The iodine is then determined by titrating with decinormal volumetric solution of sodium hyposulphite. Another method is that based upon the oxidation of arsenous acid to arsenic acid in alkaline solution by chlorinated lime. A known quantity of a decinormal solution of arsenous acid in excess being employed, this excess is determined by titration with decinormal iodine volumetric solution, starch test solution being used as an indicator. The following formulæ express the principle of this reaction: $\text{As}_2\text{O}_3 + 4\text{Cl} + 2\text{H}_2\text{O} = \text{As}_2\text{O}_5 + 4\text{HCl}$, and $\text{As}_2\text{O}_3 + 4\text{I} + 2\text{H}_2\text{O} = \text{As}_2\text{O}_5 + 4\text{HI}$.

The U. S. P. (1880) demanded a strength of at least 25 per cent, by weight, of available chlorine, which standard was raised to 35 per cent in the 1890 edition. The *French Codex* demands a minimum strength of 90 chlorometric degrees, a degree (established by Gay-Lussac), denoting the number of liters of chlorine gas (reduced to a temperature of 0° C. [32° F.], and the normal atmospheric pressure of 760 Mm.), evolved from 1 kilogram of chlorinated lime. A simple calculation shows 90 such degrees to be equivalent to 28.63 per cent of available chlorine.

Uses in Pharmacy and the Arts.—Chlorinated lime is largely used for its decolorizing action upon organic materials, its solutions, especially in the presence of acids, being powerful bleaching agents. It is employed in pharmacy in the making of chloroform, and the official solution of chlorinated soda (Labarraque's solution), which, as well as chlorinated lime itself, is an excellent deodorizer and disinfectant.

Action, Medical Uses, and Dosage.—Chlorinated lime partakes of the properties of both lime and chlorine, the most valuable constituent being the latter. Large doses produce gastric heat with nausea, vomiting, and purgation. Even moderate doses produce gastro-intestinal irritation. Externally applied, it is actively irritant, and may act as a feeble caustic. In lesser quantities it is desiccant, and counteracts gangrenous manifestations. Internally, chlorinated lime has been of considerable service in *scrofulous affections*, *mesenteric glandular enlargements*, and to control and modify the profuse and purulent secretions in *phthisis* and *bronchitis*, where it may also be used as a spray, and as a remedy in such adynamic states as *low fevers*, *typhus*, *typhoid dysentery*, and particularly in *typhoid fever*, where it is asserted to quiet delirium, moisten and cleanse the foul, dry tongue, and stimulate the dormant cutaneous functions. Externally, it is a stimulant to various indolent disorders, and a remedy for the *itch*. *Purulent ophthalmia*, *gonorrhœa*, *gangrenous*, *scarlatinal*, and *scorbutic ulcerations* of the mouth

burns, frostbites, ulcerated gums, putrid sore throat, and indolent syphilitic ulcers, are all improved by a wash of from 20 to 40 grains to the ounce of water. It removes the foul odors arising from *retained placenta*, uterine and other *carcinomata*, *fetid feet* and *axillæ*, *ozæna*, and *foul breath* due to mercurialization or to altered secretions from the tonsils and faucial glands. For *ulcers*, 4 drachms of the powder may be added to 1 ounce of lard; for *glandular enlargements*, add 1 drachm.

Chlorine is probably the best general germicide known, and chlorinated lime, which evolves it slowly, should be used in sick rooms as a disinfectant. Place it in the vessels into which septic and infectious sputa, and alvine discharges are passed. A little of the powder may also be placed in a saucer and moistened with water, or cloths may be saturated with a solution of it, and hung up in the room for general disinfecting purposes. Like chlorinated soda and its solution, it may be used to deodorize and disinfect vaults, sewers, dissecting rooms, and dead bodies preserved for police investigations should be wrapped in sheets dipped in saturated solutions of this compound. Chlorine, though an active germicide, does not exert its force readily when objects are dry, but in the presence of moisture its action is decidedly energetic. Therefore, in using bleaching powder, steam should also be generated in the room, that the chlorine may better attack the offenders. When it is desired to disinfect unoccupied rooms after sickness or death, a saturated solution of bleaching powder may be placed in the steam-moistened room, and a little sulphuric acid added to the solution, and the room closed. Care should be taken not to inhale the chlorine gas, which is rapidly liberated. The person should get out of the room as soon as possible after adding the acid.

For external use a solution prepared by adding 20 to 40 grains to 1 fluid ounce of water; for internal use the dose should be from $\frac{1}{2}$ to 4 grains, largely diluted with water, and sweetened if desired. For disinfecting purposes, use a saturated solution.

Specific Indications and Uses.—Bad breath and pallid, dirty tongue, with pasty coat, lymphatic glandular enlargements, and slow inflammations with caco-plastic deposits; inflammation of cellular structures with tendency to sloughing. Add calx chlorata, 3j to aqua Oj. Filter. Dose, 10 to 30 drops, largely diluted (Scudder).

CALX SULPHURATA (U. S. P.)—SULPHURATED LIME.

"A mixture containing at least 60 per cent of calcium monosulphide ($\text{CaS} = 71.89$), together with unchanged calcium sulphate ($\text{CaSO}_4 = 135.73$), and carbon, in varying proportions"—(U. S. P.).

SYNONYMS: *Crude calcium sulphide*, *Hepar sulphuris calcareum*, *Hepar calcis*, and improperly as *Monosulphide*, or *Sulphide of calcium*.

Preparation.—This salt, which is usually called *calci sulphidum*, or *sulphuret of lime*, is obtained by heating sulphate of calcium with powdered charcoal, or by passing a mixture of carbon dioxide and the vapor of carbon disulphide over incandescent lime (Schoene); or, by calcining calcium monoxide (lime) or calcium carbonate, with powdered sulphur. In the latter case calcium sulphate is also formed. The following directions are given by Wittstein: "Three parts of finely powdered crystallized sulphate of calcium (native gypsum), are intimately mixed with 1 part of finely powdered wood charcoal, the mixture is well pressed into an earthen or black lead crucible, covered with a thin layer of charcoal powder, and then the cover luted, with the exception of a very small opening on the top; when the luting is dry, heat is applied, at first gently, and afterward strongly, in a good wind furnace for at least 1 hour. When cooled, the crucible is removed from the fire, the upper portion of its contents taken off, the remainder powdered in a mortar, and kept in a well-closed vessel. The yield is nearly $1\frac{1}{2}$ parts." The following is the U. S. P. formula: "Dried calcium sulphate, in fine powder, seventy grammes (70 Gm.) [2 oz. av., 205 grs.]; charcoal, in fine powder, ten grammes (10 Gm.) [154 grs.]; starch, two grammes (2 Gm.) [31 grs.]. Mix them thoroughly, pack the mixture lightly into a crucible, cover this loosely, and heat it to bright redness, until the contents have lost their black color. Allow the crucible to cool, reduce the product to powder, and at once transfer to small, glass-stoppered vials"—(U. S. P.).

Description.—Pure calcium monosulphide (formula, CaS ; molecular weight, 71.89) forms a white mass, almost insoluble in water, to which, however, it gives an alkaline reaction and hepatic taste. As usually prepared, it inclines toward a gray or red tint, from iron or manganese contained in the materials, or (gray) from the presence of unconsumed charcoal. In moist air it is slowly decomposed, evolving sulphide of hydrogen. The final result of the action of the atmosphere is complete decomposition of the calcium monosulphide, with formation of calcium carbonate (CaCO_3), calcium sulphate (CaSO_4), and free sulphur. It is essential, therefore, that the salt be either freshly prepared, or else carefully preserved in glass-stoppered bottles, which should be nearly filled. The following describes crude calcium sulphide (calx sulphurata) and gives the tests of the *U. S. P.*: "A pale-gray powder, exhaling a faint odor of hydrogen sulphide, having a nauseous, alkaline taste, and gradually decomposed by exposure to air. Very slightly soluble in cold water, more readily in boiling water, which partially decomposes it; insoluble in alcohol. Sulphurated lime is decomposed by diluted acetic acid, and converted into calcium acetate and hydrogen sulphide gas which escapes, while a residue of calcium sulphate remains. The filtrate from this yields, with ammonium oxalate T.S., a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If 1 Gm. of sulphurated lime be gradually added to a boiling solution of 2.08 Gm. of cupric sulphate in 50 Cc. of water, the mixture digested on a water-bath for 15 minutes, and filtered when cold, no color should be imparted to the filtrate by 1 drop of potassium ferrocyanide T.S. (presence of at least 60 per cent of pure calcium monosulphide)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Calcium sulphide is a valuable remedy on account of its power over cellular and cutaneous inflammations, with suppuration or tendency to suppurate. Not only does it influence glandular and lymphatic structures, proving a good remedy in *suppurative adenitis*, but it undoubtedly has some control over the body fluids, such as to prevent suppuration from inflammations of the soft structures. In cases tending to the formation of pus, resolution will take place if the condition be recognized early enough and the drug administered; if past the stage for resolution suppuration will be hastened by it, though the amount of broken-down tissue and consequent quantity of purulency will be less than if the suppurative process proceeded without its aid. It is the best antissuppurative known when the condition is not due to syphilis, and even in the secondary stage of the latter it is not without good effects, but other agents, notably berberis aquifolium, are regarded more efficient. The mucous surfaces (the internal integuments) are also influenced by it, and suppurative action checked as in the purulent stages of *bronchitis* and *pneumonia*. It is a well-established remedy for certain forms of *nasal catarrh*—those in which secretion is abundant with a tendency toward purulency, and where the patient readily takes repeated colds. In this condition the 2 x trituration is to be preferred. It is a remedy in *chronic pharyngitis* and in *diseases of the larynx*, with impairment of voice; also after *pneumonia*, where small suppurative points or deposits linger in the wake of the disease. Prof. Locke (*Syllab. Mat. Med.*) commends it in the *cough of phthisis* following *syphilis*. In *chronic skin diseases* it is adapted where the epidermal tissues undergo a change, and also in those forms in which *suppurative pimples* form. *Eczema*, in scrofulous subjects, is amenable to it, and, while it tends to check suppurative action in *acne*, it does not always check the disease. As a remedy for successive crops of *boils* no agent is superior, though alnus is a close second.

Sulphide of calcium, in order to be of therapeutical value, must possess the odor peculiar to sulphides, which is very similar to that of rotten eggs. This remedy is particularly valuable in *boils*, *carbuncles*, *suppurating scrofulous ulcers* in the neck, *scrofulous sores*, *soreness of the throat* with glandular enlargement, occurring in *measles* or in *scarlatina*, *enlarged testes*, *indolent* and *suppurative buboes* and *soft chancres*, *acne*, *mammary abscess*, *anal fistula*, etc. Its influence on the suppurative process, as stated by Prof. S. Ringer, is as follows: A thin, watery, unhealthy discharge, becomes, at first, more abundant, then diminishes, and becomes thicker and healthier, like "laudable" pus, the condition of the sore improving correspondingly, and its healing being promoted. In some cases, any pain that exists is temporarily aggravated, but, as a rule, it is speedily mitigated. The general

health improves, and the debility and malaise, so frequently attending these maladies, promptly passes away. In cases where inflammation and severe pain are present, he advises the smearing of the parts with a mixture of equal parts of belladonna extract and glycerin, covering this with a small poultice, at the same time protecting the surrounding skin from the tendency of the poultice toward the production of a fresh crop of boils, etc., by the application of a piece of leather with a hole in it large enough to contain the boil or affected portion. The dose varies from $\frac{1}{16}$ grain to $\frac{1}{2}$ grain, every 2 or 3 hours, and the treatment requires to be continued for several weeks. Ordinarily $\frac{1}{2}$ of a grain rubbed up with 2 or 3 grains of sugar of milk, will be a sufficient dose. Dr. S. Sexton, of New York, and others have derived much benefit from sulphide of calcium in cases of *furuncular inflammation of the external meatus auditorius*, when suppuration was threatened, or had already occurred. Foltz gives 1 grain of the 1 x or 2 x trituration to prevent suppuration in *acute otitis media*, and continues its use if suppuration becomes established. He uses it also (1 grain of 1 x or 2 x trituration, every 3 hours) in *dacryo-cystitis*, in crops of *styes*, which it will generally prevent, *ciliary blepharitis*, with tendency to pustulation, and declares it the drug in *suppurative affections* of the cornea, conjunctiva, and deeper eye structures (*Dynam Therap.*) Dr. Solomon, of Birmingham Hospital, England, has found the sulphide of calcium efficient in cases of *chronic vascular keratitis* (strumous), when accompanied with cold extremities and other indications of impaired circulation; he dissolves 1 grain of the sulphide in $\frac{1}{2}$ pint of water, and administers the solution in doses of from 1 to 4 fluid drachms, repeated every 2, 3, or 4 hours. In acute cases, he has found it injurious, and, in patients of a sanguine temperament, it acts as a stimulant. In doses of $\frac{1}{2}$ of a grain, rubbed up with 3 grains of sugar of milk, and repeating the dose 3 or 4 times daily, this agent is reported to have been successful in the treatment of *diabetes*; but further experiments are required before much confidence can be placed in this statement. Larger doses of the sulphide of calcium than those stated above, are apt to derange the digestive functions; with children they should be less.

The dose of calcium sulphide ranges from $\frac{1}{16}$ to 2 grains; many, however, prefer 2 to 5-grain doses of the 1 x or 2 x trituration, given every 2 or 3 hours. Calcium sulphide gives the best results in chronic cases, and a disagreeable feature of its administration is the eructation of sulphuretted hydrogen, the drug being decomposed in the stomach.

Specific Indications and Uses.—Inflammation of areolar or connective tissue, with tendency to suppuration; to prevent suppuration, or to hasten it after once established, thus saving extensive tissue destruction; successive crops of boils or styes; pustular eruptions; lymphatic torpor, with tendency to purulency; feeble recuperative powers after exhaustive purulent diseases; suppuration of the ear or eye and appendages; purulent catarrhal states; scrofula and struma.

Related Compounds and Preparations.—**CALCII OXYSULPHURETUM.**—This is *sulfure de calcium* of the French, and is a mixture of oxy-sulphide and sulphate (or thiosulphate) of calcium, in variable proportions. It occurs in grayish-green or gray masses, and should be securely kept in glass-stoppered vials. It is prepared by boiling, with frequent stirring, calcium hydroxide (300 parts), sulphur (100 parts), and water (500 parts). When of the proper consistence to solidify, it is poured upon a slab of marble until cool, when it is at once transferred to bottles.

MARTIN'S DEPLATORY.—When a current of hydrogen sulphide is passed into a mixture of calcium hydroxide (2 parts) and water (3 parts), until no more will be absorbed, a semi-solid mass of pronounced sulphurous smell, and known by the foregoing name, is produced. Its depilatory action is so perfect that but a very few moments' application suffices to remove the hair. Upon standing it is separated into 2 parts which, before using, must again be mixed. This preparation contains calcium hydrosulphide ($\text{Ca}[\text{HS}]_2$).

CAMBOGIA (U. S. P.) GAMBOGE.

"A gum-resin obtained from *Garcinia Hanburii*, Hooker filius"—(U. S. P.). (*Garcinia Morella*, Desrousseaux, var. *pedicellata*, Hanbury).

Nat. Ord.—Guttiferæ.

COMMON NAMES: *Gamboge*, *Camboge*, *Gutti*, *Gummi-resina gutti*, *Cambodia*, *Gutta gamba*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 33.

Botanical Source and History.—This plant differs from that of *Garcinia Morella* (*G. pictoria*), described below, in having *pedicellate* male flowers. It has glossy leaves resembling those of the laurel, and bears yellow flowers.

Gamboge was first brought to Europe by Admiral Van Neck, in 1608, who gave a specimen of it to Prof. Clusius, of Leyden (*Amer. Jour. Pharm.*, 1837). In relation to the plant from which this gum-resin is derived, there was formerly much confusion. By some it was laid down as coming from *Stalagmitis cambogioides*, upon the authority of Murray, but Dr. Graham has satisfactorily determined that there is no such plant in existence. It was then supposed to be derived from trees of Ceylon, which produce gum-resins agreeing closely or entirely with the official gamboge (the *Garcinia Cambogia* and the *Hebradendron cambogioides*, which last was supposed to be the tree from which it was principally collected), though on merely presumptive evidence. The latter tree is not now recognized under the name *Hebradendron*, but is regarded by botanists as identical with *Garcinia Morella* of Desrousseaux. Hanbury also regards the *G. elliptica*, Wallich, as identical, the product of which is certainly identical with commercial gamboge. The matter was best presented by Mr. Hanbury, who investigated the subject, finding that the gum was the product of a variety of the above mentioned *Garcinia Morella* of Desrousseaux (*Garcinia pictoria*, Roxburgh; *Hebradendron cambogioides*, Graham), and to that variety he gave the name *Garcinia Morella*, var. *pedicellata*, on account of its pedicellate, male flowers. The younger Hooker, however, regarded it as sufficiently distinct from the *Garcinia Morella* to entitle it the rank of a species, and accordingly gave it the title, *Garcinia Hanburii* (see Hanbury, "On the species of *Garcinia* which affords Gamboge in Siam," *Tr. Linn. Soc.*, Vol. 24, p. 487).

The *Garcinia Morella*, Desrousseaux, is a moderate-sized tree, with opposite petiolate, obovate-elliptical, coriaceous, smooth, entire, abruptly-acuminate, shining leaves, which are dark-green above and paler beneath. The flowers are unisexual, sessile, and axillary; the calyx membranous and persistent, consisting of 4 sepals; the corolla is 4-petaled, while the fruit is a pleasant, saccharine, quadrilocular berry, about the size of a cherry, crowned with a sessile stigma, containing 1 seed in each division (L.). In order to obtain the gum-resin incisions are made into the tree, or a large slice is pared from the bark, from which the juice flows thick, viscid, and bright-yellow, which is scraped off and dried in the sun. If left on the tree, it speedily concretes into dry tears or irregular masses. It is more generally collected, however, by making incisions into the bark, into which bamboo joints are inserted to catch the oozing fluid, which subsequently solidifies. It is removed from the bamboo by slowly rotating them over a fire until the water has dried out sufficiently to allow the receptacle to be detached from the hardened gamboge. The first process described is that by which the Ceylon gamboge is collected. The best kinds are the *pipe gamboge* and *Ceylon gamboge*, which last is seldom found in our country. The pipe gamboge consists of cylindrical pieces, often cohering together, forming irregular masses weighing several pounds. *Lump or cake gamboge* occurs in masses of several pounds weight; it differs from the best pipe gamboge in containing between 5 and 10 per cent of starch, and fragments of wood, twigs, and air cells. Gamboge is used in painting as a yellow pigment, known in Europe as *gummigutt*. It is collected in Siam and Cochin-China, and principally in Cambodia, and sent to Singapore, Saigon, and Bangkok, from which places it is imported into this country.

Description.—Gamboge, to meet the official demands, should conform to the following description and tests: "In cylindrical pieces, sometimes hollow in the center, 2 to 5 Cm. ($\frac{1}{2}$ to 2 inches), in diameter, longitudinally striate on the surface; fracture flattish-conchoidal, of a waxy luster, orange-red; in powder bright yellow; inodorous; taste very acrid; the powder sternutatory. Gamboge is partly soluble in alcohol and in ether. When triturated with water it yields a yellow emulsion, and forms, with solution of potassium or sodium hydrate, an orange-red solution, from which, on addition of hydrochloric acid, a yellow resin is precipitated. Boiled with water, gamboge yields a liquid which, after cooling, does not become green with iodine T.S. (absence of starch)"—(*U. S. P.*). Ether and water when used alternately, dissolve the whole of pure gamboge. Alcohol dissolves all the resin, leaving the gummy matter, and ammoniated alcohol forms a solution with it which is not changed by water.

Chemical Composition.—Gamboge consists mainly of resin (71.6 to 74.2 per cent), gum (21.8 to 24 per cent) moisture (4.8 per cent), traces of starch and woody fiber (Christison). The resin has the nature of an acid (*gambogic acid*), and is the active principle of the gum. Its specific gravity is 1.221. It forms soluble salts with alkalies, and insoluble precipitates with salts of heavy metals; this class of compounds has been called *gambogiates*. The resin is obtained by extracting gamboge with ether (whereby the gum is left behind), and evaporating the solution to dryness. It occurs in brittle masses of a deep orange color, insoluble in water, but soluble in alcohol, ether, chloroform, carbon disulphide, and caustic alkali, with which it forms an orange-red solution, from which acid again precipitates the yellow resin. Gambogic acid imparts a perceptible yellow hue to 10,000 times its weight of spirit or water (C.).

Pereira gives the following as the tests for distinguishing gamboge: "Gamboge emulsion becomes transparent and deep-red on the addition of potassa, forming *gambogiate of potassium*. Digested in alcohol or ether, gamboge yields orange-red tinctures (*solutions of gambogic acid*). The ethereal tincture dropped on water yields, on the evaporation of the ether, a thin, bright-yellow, opaque, film or scum (*gambogic acid*), soluble in caustic potash. The alcoholic tincture dropped into water, yields a bright, opaque, yellow emulsion, which becomes clear, deep red, and transparent, on the addition of caustic potash. The *gambogiate of potassium* (obtained by any of the above processes), gives, if the alkali be not in excess, with acids, a yellow precipitate (*gambogic acid*); with acetate of lead, a yellow precipitate (*gambogiate of lead*); with sulphate of copper, brown (*gambogiate of copper*); and with the salts of iron, dark brown (*gambogiate of iron*)."

Hlasiwetz and Barth (1866), in fusing the purified resin of gamboge with potassium hydroxide, obtained several acids, among them *acetic*, *pyro-tartaric* ($C_4H_4O_6$), and *isovitinic* ($C_6H_4CH_2[COOH]_2$) acids; also *phloroglucin* ($C_6H_3[OH]_3$). The vapor given off during fusion had the odor of balm and lemons. The presence of wax has also been indicated by Hurst, in 1889 (Flückiger).

Action, Medical Uses, and Dosage.—In large doses gamboge is a powerful irritant, causing gastro-enteritis and death; it is said to produce diffuse inflammation of the cellular tissue, when applied beneath the skin. On account of its severity of action, and its liability to cause serious symptoms, it is seldom employed singly as a purgative; yet when combined with other cathartics it forms a safe and excellent physic. It may, however, be safely administered alone in moderate doses, by reducing it to a state of fine division with other comparatively inert powders, as sulphate or bitartrate of potassium. It thus operates effectually as a hydragogue, without occasioning much tormina or constitutional exhaustion. In medicinal doses, it is a drastic, hydragogue cathartic, causing nausea, griping, and copious watery stools, on which account it is often used in *dropsy*, in combination with squills, cream of tartar, etc. It has also been used for the expulsion of *tapeworm*, in *torpor of the bowels*, *dysmenorrhœa*, etc. Two grains of sulphate of quinine combined with $1\frac{1}{2}$ grains of gamboge, and administered 3 times a day, have been highly recommended in cases of long-continued *constitutional debility*, with constipation. United with an alkali, it proves diuretic.

Its use is contraindicated in gastritis, enteritis, during pregnancy, menorrhagia, hemorrhoids, in excited, irritable, or diseased uterus, and where there is irritation or disease of the urinary organs. When taken in large doses, or when it acts with severity, the best remedy to counteract its dangerous effects is a solution of some alkaline substance, as sodium bicarbonate, to be followed by general treatment if inflammatory symptoms be present. Dose, in pill, powder, or alkaline solution, from 1 to 15 grains; the larger doses given in small quantities, and repeated at short intervals until it operates.

CAMPHORA (U. S. P.)—CAMPHOR.

FORMULA: $C_{10}H_{16}O$. MOLECULAR WEIGHT: 151.66.

"A stearopten (having the nature of a ketone) obtained from *Cinnamomum Camphora* (Linné) Nees et Ebermaier, and purified by sublimation (U. S. P.); (*Laurus Camphora*, Linné; *Camphora officinarum*, C. Bauhin)."

Nat. Ord.—Laurineæ.

COMMON NAMES: *Laurel camphor*. (Tree) *Camphor laurel*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 222.

Botanical Source.—The *Cinnamomum Camphora* is a large tree with lax, smooth branches. The leaves are evergreen, alternate, on long, slender, smooth petioles, somewhat coriaceous, oval, acuminate, attenuate at the base, bright-green and shining above, paler beneath, triple-nerved, with a sunken gland at the axils of the principal veins, projecting at the upper side and opening by an oval pore beneath. The flowers are small, smooth, yellowish-white, in axillary and terminal, naked corymbose panicles. The leaf-buds are scaly. The fertile stamens are 9 in 3 rows; the inner with 2, compressed, stalked glands at the base; the anthers 4-celled; the outer ones turned inward; the inner ones outward. Three sterile stamens are placed in a whorl alternating with the stamens of the second row; 3 others are stalked, with an ovate glandular head. The fruit is placed on the obconical base of the calyx (L.).

History.—Camphor, obtained from the *Cinnamomum Camphora*, and, in the crude state, is imported into this country, principally from Canton, where it undergoes purification by sublimation, before it is in a state adapted to medicinal use. The camphor tree inhabits the eastern and warmer latitudes of Asia. It thrives in warm countries and is cultivated by the Italians for ornamentation. It is an aromatic tree, all parts of it yielding the odor and giving the taste of camphor. Camphor is obtained in Japan by cutting the wood, roots, etc., of the tree in small pieces, boiling them in water, in large iron stills, fitted with earthen heads, containing straw cones. The water is kept boiling for about 48 hours, the camphor sublimes and concretes upon the straw in the head, in the form of a gray powder. It appears in commerce as whitish, dry, granular cakes, slightly tinged with red, and is known as *Japan camphor*, or *Tub camphor*, on account of being imported in a double tub. It was once commercially known as *Dutch camphor*. The Chinese pursue a different process. They steep the chopped branches in water, then boil it, continuing the ebullition until a stick placed in the fluid will, when cooled, be covered with the camphor. The liquor is then strained, and by cooling, the camphor solidifies. This is then placed alternately in layers, with powdered dry earth, in a copper vessel, over which another one is placed, and the camphor, being sublimed by heat, attaches itself to the upper inverted vessel. It is of a dirty grayish color, and is known as impure or crude camphor. Though prepared by the Chinese and known as Chinese camphor, it is manipulated in Formosa. None is made in China. It sometimes appears in the market like the preceding in appearance, but oftener of a darker hue, in smaller particles, and in a moist condition. It is packed in chests, covered inside with sheet-lead or tin, and is known as *Chinese camphor*, or *Formosa camphor*. In Formosa, camphor is also prepared by allowing the camphorated steam to collect on earthen receivers placed over the vaporizing troughs. Camphor is now refined in this country. Vessels similar to the *bombaloes* of Europe (large globular glass vessels), are sometimes used, differing, however, from the European apparatus in being made in sections, so that they can be readily taken apart and the camphor removed. To remove the sublimate from the *bombaloes* (of Europe) the latter must be broken. It may also be sublimed slowly and cautiously from retorts into a receiving chamber, as "*flowers of camphor*," a fine crystalline state which, by powerful pressure, may be made to form cakes. Japan, since the acquisition of Formosa, now has a monopoly of Chinese camphor.

The camphors are closely related to the different varieties of turpentine. Two species are known in the East, viz.: *Borneo camphor* ($C_{10}H_{16}O$), obtained from a very large tree, the *Dryobalanops Camphora*, Colebrooke, which is so highly prized by the natives that it rarely finds its way to our markets; and the *Laurel camphor* ($C_{10}H_{16}O$), from the *Cinnamomum (Laurus) Camphora*, and which is the ordinary camphor of commerce. Many other plants furnish camphor by oxidation of their essential oil, as lavender, rosemary, marjoram, pennyroyal, peppermint, feverfew, etc. Amber and the oils of valerian, sage and tansy, also yield it when treated with nitric acid.

Description.—"White, translucent masses, of a tough consistence and a crystalline structure, readily pulverizable in the presence of a little alcohol, ether, or chloroform; having a penetrating, characteristic odor, and a pungently aromatic

taste. Specific gravity: 0.995 at 15° C. (59° F.). Very sparingly soluble in water, but readily soluble in alcohol, ether, chloroform, carbon disulphide, benzine, and in fixed and volatile oils. When camphor is triturated, in about molecular proportions, with menthol, thymol, phenol, or chloral hydrate, liquefaction ensues. It melts at 175° C. (347° F.), boils at 204° C. (399.2° F.), and is inflammable, burning with a luminous, smoky flame. On exposure to the air it evaporates more or less rapidly at ordinary temperatures, and, when moderately heated, it sublimes without leaving a residue. Camphor should be kept in well-closed vessels, in a cool place"—(U. S. P.).

Camphor is somewhat unctuous to the touch and, besides being pungent to the taste, it imparts an after-sense of coolness. It is so tough and elastic as to almost defy pulverization, which may be readily accomplished, however, by adding a few drops of alcohol or any of the agents above mentioned. Besides the above-named solvents, acetone dissolves it. It requires about 1300 parts of water for solution; sugar, magnesia, carbonic acid, corrosive sublimate, or spirit of nitrous ether render it more soluble in water. Resins and fats, when heated with it, unite in all proportions. Three isomeric modifications of camphor are known; they can not be distinguished from each other, except by their action upon a ray of polarized light; one of the varieties produces rotation of the ray to the right; the second variety produces left-handed rotation; whilst the third has no sensible effect upon polarized light. The common camphor of commerce, and that obtained by the action of nitric acid upon *borneol*, is the right-handed modification. The camphor contained in the oil of *Pyrethrum* (*Matricaria*) *Parthenium* exerts a left-handed rotary action upon a ray of polarized light (Chautard); whilst, according to Biot, the camphor deposited by oil of lavender is destitute of any such rotary effect upon a polarized ray. By the application of polarized light, the smallest portion of natural camphor may be distinguished from the artificial camphor (hydrochlorate of camphene). If small fragments of each be placed separately on glass slides, and a drop of alcohol added to each, they dissolve, and speedily recrystallize. If the crystallization of the natural camphor be watched by means of the microscope and polarized light, a most beautiful display of colored crystals is seen, while with the artificial camphor nothing of the kind is witnessed. Camphor is lighter than water, and keeps up a constant rotary motion when small pieces are placed on that fluid.

When camphor is triturated with dragon's blood, guaiacum, galbanum, or asafoetida, the mixture preserves the pilular consistence indefinitely. With benzoin, tolu, mastic, and ammoniac, the mixture becomes soft when exposed to the air. With olibanum, gamboge, euphorbium, amber, and myrrh, the mixture remains pulverulent, though grumous. Asafoetida, galbanum, sagapenum, tolu, dragon's blood, olibanum, mastic, benzoin, tacamahac, guaiacum, and ammoniac, destroy to a greater or less extent the odor of camphor (M. Planché).

Chemical Composition.—The class of substances known as camphors, of which *Japan camphor* ($C_{10}H_{16}O$) is a representative, are products of oxidation of the group of hydrocarbons, known as *terpenes*. These are mostly all isomers of the formula $C_{10}H_{16}$, and, in turn, are hydrogen addition products of the hydrocarbon, *cymol* (*cymene*) ($C_{10}H_{14}$), or para-methyl-iso-propyl-benzene, having the graphic formula $C_6H_4.(CH_3).(C_2H_5)$.

Japan camphor may be converted into *cymol* by distillation with zinc chloride, or with phosphoric anhydride, which agencies abstract from camphor the elements of water, thus: $C_{10}H_{16}O - H_2O = C_{10}H_{14}$. On the other hand, camphor may be obtained (in small amounts) by the oxidation of terpenes. When heated with iodine, ortho-oxycymol (*carvacrol*), an isomer of thymol is formed. These various reactions point to the following graphic formula for Japan camphor:

Borneol ($C_{10}H_{18}O$), the camphor obtained from *Dryobalanops Camphora*, stands to Japan camphor in the simple relation of a secondary alcohol to a ketone. Consequently, borneol, by mild oxidation, yields Japan camphor, and from the latter, inversely, Borneo camphor may be obtained by reduction with sodium in alcoholic solution. When Japan camphor is heated with nitric acid on a boiling water-bath, *camphoric acid* ($C_{10}H_{16}O_4$) is formed; upon continued oxidation, cam-

phoronic acid ($C_{10}H_{16}O_5$) results. When treated with concentrated sulphuric acid, Japan camphor yields a black solution, from which, upon dilution with water, an oily body, *camphene* ($C_{10}H_{16}$), is precipitated. This substance, which is an isomer of the terpenes, forms, with hydrochloric acid, a crystalline compound, which has the smell of camphor, and is known as *artificial camphor*. It is obtained by passing into oil of turpentine dry hydrochloric acid gas and cooling the compound formed. Artificial camphor melts at $125^{\circ}C.$ ($257^{\circ}F.$) and boils at $210^{\circ}C.$ ($410^{\circ}F.$).

The *camphresinic acid* of Schwanert (1863) has been shown to be a mixture of camphoric and camphoronic acids. *Oxycamphor* ($C_{10}H_{14}O_2$) in white, acicular crystals, possessing the characteristic taste and odor of camphor, results from treating camphor with the weaker oxidizing agents (notably hypochlorous acid), and acting upon the bodies thus formed with a solution of caustic potash in alcohol (Wheeler, 1868). With bromine, camphor forms unstable garnet-red crystals, having the composition $C_{10}H_{14}OBr_2$, which yield, on being heated to between 80° and $90^{\circ}C.$ (176° to $194^{\circ}F.$), an amber liquid, and evolve hydrobromic acid. On cooling, the liquid congeals, yielding crystals of monobromide of camphor, which may be purified by means of boiling alcohol. Chlorine also unites with camphor, forming monochlorine and dichlorine camphors, while iodine forms with camphor a substitution product.

ACIDUM CAMPHORICUM.—*Camphoric acid* ($C_{10}H_{16}O_4$). Camphoric acid is an oxidation product from boiling camphor and nitric acid, or permanganate of potassium, usually the former. It may be prepared by heating camphor with 10 times its weight of concentrated nitric acid. It presents odorless needle-like crystals, having a faintly acid taste. It is soluble in boiling, but very sparingly soluble in cold water. Fats, essential oils, ether and alcohol also dissolve it. It is a bibasic acid, fuses at $70^{\circ}C.$ ($158^{\circ}F.$), and may be rendered anhydrous by sublimation. There are 3 isomeric modifications of it, determined by their action upon a ray of polarized light.

Action, Medical Uses, and Dosage.—In large doses camphor is a narcotic and irritant; in small ones, sedative, anodyne, antispasmodic, diaphoretic, and anthelmintic. Very small doses stimulate and large doses depress. Large doses cause oesophageal and gastric pain, vomiting, slow and enfeebled and subsequently intermittent pulse, dizziness, drowsiness, dimness of sight, pallid, cold skin, muscular weakness, cyanosis, spasms, muscular rigidity, and convulsions. Several deaths have resulted from its use, other circumstances contributing somewhat to the fatal issue, but cases of death in a healthy individual have been reported. Mental confusion may follow its excessive use. Its effects in small doses are transient, but are not followed by depression or exhaustion. It exerts an influence on the brain and nervous system, exhilarating and relieving pain, is an excitant to the vascular system, and irritates mucous tissues which are in proximity with it. When given in the solid form, it is capable of producing ulceration of the gastric mucous membrane. It is used to allay nervous excitement, subdue pain, arrest spasm, and sometimes to induce sleep. In the delirium, watchfulness, tremors, and starting of the tendons in *typhoid conditions*, it is of much utility as a *nervo-stimulant*. *Occipital headache*, from mental overwork, is relieved by small doses, and the external application of camphor. Large doses (grs. xx) are required in *maniacal excitement*. In *inflammatory affections*, as *remittent and intermittent fevers*, *acute rheumatism*, etc., it acts beneficially as a diaphoretic and sedative; and is also valuable in *gout*, *neuralgia*, *dysmenorrhæa*, *after-pains*, *puerperal convulsions*, and *painful diseases of the urinary organs*, acting as a sedative, anodyne, and antispasmodic. It is often advantageously combined with opium in *chordee*, and *hysterical nymphomania*, and all *irritations of the sexual organs*. It relieves the *strangury* caused by the use of cantharides. By some physicians it is said to act as an aphrodisiac, exciting the reproductive organs, causing considerable heat in the urethra, and nocturnal emissions; others, again, use it as an ant-aphrodisiac, and to diminish urino-genital irritation. For the first purpose small doses are effectual; for the second, large sedative doses are requisite. It is said to be an antidote to *poisoning by strychnine*, and has been used in *poisoning from illuminating gas*. An oleaginous injection of camphor in the early stages of *gonorrhæa* often allays urethral irritation, as well as the tenesmus caused by *thread-worms*, *flux*, etc., when injected into the rectum. It enters into many embrocations and

liniments for *rheumatic, neuralgic, and deep-seated pains, cynanche tonsillaris, contusions from blows, sprains, chilblains, chronic cutaneous diseases*, and as a stimulant for *indolent and gangrenous ulcers*. The itching of *smallpox pustules* is said to be relieved by it. It has been found beneficial in *asthma and spasmodic cough*; and the powder may be used as a snuff for the relief of *nervous headache*, and *catarrh* in its commencing stages. Camphor is a remedy of marked value in many *bowel troubles*, and is usually used in combination with pain-relieving agents for that purpose. Evidence is strong in its favor as an agent in *Asiatic cholera*. The nervous manifestations of *la grippe* seem to be controlled by small doses of camphor. Spirits of camphor and camphorated oil are well known to allay the pain attending *acute mastitis*, and to check the lacteal secretion. The spirit, on cotton, sometimes allays *toothache*. The best form of using an aqueous solution of this agent is the aqua camphoræ. The administration of opium will best neutralize the evil effects of an overdose of camphor. Small and repeated doses of alcohol may also be given. Dose of the powder, 1 to 10 grains; aqua camphoræ, ℥iij to ℥iv; spirits of camphor, 1 to 30 drops.

CAMPHORIC ACID is sedative and antiseptic. It has been lately advocated as an efficient remedy for the *night-sweats of pulmonary consumption*. It is considerably employed in 1 per cent solution in *catarrhal diseases*, both acute and chronic, good results being reported from its use in *sore throat, acute nasal catarrh, acute bronchitis, irritable bladder, cystitis* (acute and chronic), *strangury, enuresis*, and *nocturnal seminal emissions*. It has made some impression for good in *spasmodic states*, as *epilepsy, hysteria, and chorea*. For local use it may, if desired, be combined in solution with borax, or boric acid. The dose is from 10 to 25 grains in solution or in capsules. Solutions of from 1 to 4 per cent are locally employed.

Specific Indications and Uses.—"Insomnia and restlessness, the pulse being soft and tongue moist; diarrhœa" (Scudder). Low grades of inflammation and fevers, particularly typhoid, with great restlessness, morbid watchfulness, muttering delirium, subsultus, dry skin, and quick, irritable pulse (Locke); *strangury*; urination frequent, difficult, and tenesmic. For specific use $\frac{1}{2}$ to 1 grain doses. In minute doses in burning pain in stomach; dizziness, nausea, and vomiting; weak, husky voice; cyanotic countenance, with cold extremities.

Related Camphors and Camphor Oils.—Many essential or volatile oils, when subjected to distillation, yield a product liquid at ordinary temperatures, which is a hydrocarbon (usually of the terebenthene class or series $C_{10}H_{16}$), often termed an *eleopten*, and a portion solid at ordinary temperature, an oxidation product known as a *stearopten*. The latter often exists as a vegetable exudate, or may be derived from vegetation by proper treatment. It has a higher boiling point than the *eleopten*. The *stearoptens* are known under the general and elastic term *camphors*, and have the general composition $C_{10}H_{16}O$, and, though obtained from many plants, it is altogether probable that they are identical with laurel camphor.

BORNEO CAMPHOR. *Camphol, Borneol, Malayan camphor, Camphyl alcohol, Sumatra camphor, Barus camphor, Dryobalanops camphor*.—Composition $C_{10}H_{16}O$. Found under the bark and in fissures of the trunk of *Dryobalanops Camphora*, Colebrooke (*Dryobalanops aromatica* of Gaertner), of the natural order *Dipterocarpaceæ*. India, Sumatra, and Borneo.

Borneo camphor contains 2 atoms more of hydrogen than common camphor. It is an alcohol yielding ethers with acids. It requires a heat of $198^{\circ}C.$ ($388^{\circ}F.$) to melt it, is less volatile, but denser and harder than ordinary camphor; it boils at $211.6^{\circ}C.$ ($413^{\circ}F.$). Its smell, solubility, and general appearance are like those of common camphor, and it exerts a somewhat more feeble right-handed rotary action upon polarized light. On account of its crystallizing in the regular system, however, it is stated by Descloizeaux (1870) and confirmed by Flückiger (1874), that it displays no colors under the polarization microscope. Its taste differs from that of ordinary camphor in being both camphoraceous and hot and peppery. It crystallizes in small, transparent, regular, colorless, 6-sided prisms, and is converted into ordinary camphor when gently heated with nitric acid of moderate strength, which causes a loss of 2 atoms of its hydrogen. It is naturally associated with an oil termed borneène ($C_{10}H_{18}$), which is isomeric with oil of turpentine and with *valerene*, and which is removed by distillation in order to obtain the camphor free from it. *Dryobalanops camphor* is a little heavier than water and falls to the bottom, while the laurel variety floats. It does not possess the gyratory movements of the laurel camphor; has generally a tabular form; is an amorphous odor, and is usually accompanied with foreign substances, among which are amorphous resin, neither acid nor volatile, but which, when heated, gives out an odor of colophony. Borneol may be made artificially by hydrogenating laurel camphor. Borneo camphor is sold at an excessively high price in the East and is never found in our markets.

NGAI CAMPHOR, Blumea camphor.—A camphor identical in composition ($C_{10}H_{16}O$) with borneol, but different in turning the ray of polarized light, as much to the left as borneol does to the right; derived from a southeastern Asia composite plant, known to the Chinese as *Ngai*,

and to botanists as *Blumea balsamifera*, De Candolle. By oxidation with nitric acid it yields a camphor identical in composition with laurel camphor ($C_{10}H_{16}O$), but still retaining its levogyre behavior. It is prepared in Canton and the Hainan Isle, and used by the Chinese as a medicine and in perfuming choice Chinese inks. Its price being about tenfold higher than that of common camphor, prevents its occurrence in European and American commerce. Its physical appearance, after sublimation, is identical with that of borneol.

Blumea lacera is used in India as an insecticide. It yielded Dymock, a pale-yellow essential oil of extraordinary left-rotating power. Its density, at $28.6^{\circ}C$. ($80^{\circ}F$.), is 0.9144.

CHAMPACA CAMPHOR.—*Champacol* ($C_{17}H_{26}O$). A new camphor from champaca wood. Isolated by Merck (1893).

FORMOSA CAMPHOR OIL. *Camphor oil of Formosa, Oleum camphoræ* (U. S. P., 1870), *Camphor oil*.—This oil is drained off the crystals of crude camphor in the preparation of the latter, and prepared to some extent when camphor is refined. It is a brownish-colored liquid, holding in solution quite a quantity of camphor, which crystallizes out of the oil when the latter is subjected to a reduced temperature. It has the taste of common camphor and a sassafras-like odor, by which it may be readily distinguished from Borneo camphor oil (*Pharmacographia*). It has a density of 0.940; its boiling point is near $180.5^{\circ}C$. ($357^{\circ}F$.). Like laurel camphor it is dextrogyre in behavior. Flückiger (*Pharmacognosie*, 1891) mentions as the constituents of this oil the following: *Dipentene* (cinene) ($C_{10}H_{18}$), a hydrocarbon boiling at $182^{\circ}C$. ($359.6^{\circ}F$.), capable of yielding addition products with bromine ($C_{10}H_{18}Br_2$), fusing point $126^{\circ}C$. ($255.2^{\circ}F$.); also with hydrochloric acid ($C_{10}H_{18}[HCl]_2$), and with water ($C_{10}H_{18}[H_2O]_2$). Besides, Schimmel & Co. (*Report*, Oct., 1888) made known the following constituents: Pinene, phellandrene (both $C_{10}H_{18}$), cineol ($C_{10}H_{18}O$), safrol, eugenol, and a considerable amount of a hydrocarbon, identical with that obtainable from cubeba.

BORNEO CAMPHOR OIL. *Camphor oil of Borneo, Sumatran camphor oil, Bornéene*.—An oil derived from the tapped or felled trees (*Dryobalanops Camphora*, Colebrooke) which yield Borneo camphor. It has been said to be secreted in such great quantities in old trees, and to exert such great pressure as to disrupt the trunk of the tree, the bursting causing a report like that from a cannon. A similar phenomenon is said to take place in the tree furnishing copaiba balsam (*Pharmacographia*). Bornéene ($C_{10}H_{18}$) is isomeric with pure turpentine, and is a volatile, viscid, brownish-red oil, composed of borneol and resin dissolved in borneene, a liquid having a turpentine-like odor, and identical with the *valerene* of valerian oil. It does not deposit Borneo camphor on standing even when subjected to a very low temperature. In its optical properties it is dextrogyre.

Camphor Preparations.—**VINUM CAMPHORATUM.** *Wine of camphor*.—This is a turbid, whitish fluid, prepared according to the *German Pharmacopœia*, by dissolving 1 part of camphor in 1 part of alcohol and incorporating gradually, and with agitation, 3 parts of mucilage of acacia and 45 parts of white wine. Its use is the same as that of spirits of camphor, and it must be shaken before dispensing and administering.

CAMPHORA CARBOLISATA. *Camphora phenolata, Carbolated camphor, Phenol camphor, Camphorated phenol*.—An oily or colorless liquid, having a camphoraceous odor, practically insoluble in glycerin and water, but soluble in alcohol, fixed oils and ether. Hager prepares it by dissolving 100 parts of camphor and 36 parts of carbolic acid in 4 parts of alcohol: Bufalini, by allowing 2 parts of camphor and 1 part of phenol to liquefy. A local anæsthetic and antiseptic. Ten-drop doses of an olive-oil solution have been given in *catarrh of the stomach*, and the same applied has arrested *erysipelas*. *Wounds, ulcers, boils, and herpetic skin affections*, as well as *diphtheric membranes*, have been painted with it, and *ulcerine leucorrhœa* locally treated with it, with asserted relief. It is said to relieve the pain of *ingrown nails* and *dental caries*.

CAMPHORA SALICYLATA. *Salicylated camphor*.—Heat, by means of a water-bath, to $90^{\circ}C$. ($194^{\circ}F$.), a mixture of 65 parts of salicylic acid and 84 parts of camphor until liquefaction takes place (Guirleo). An oily fluid, devoid of color, and becoming a solid opaque mass which, when triturated, assumes an unctuous consistence. Fixed and volatile oils dissolve it, while it is much less soluble in water or glycerin. Useful, locally, in *syphilitic phagedæna* and *ulcerations*. Suppositories are sometimes made of it by combining it with 10 to 15 parts of petrolatum, with a little paraffin added to give hardness.

CAMPHORA MONOBROMATA (U. S. P.)—MONOBROMATED CAMPHOR.

FORMULA: $C_{10}H_{15}BrO$. **MOLECULAR WEIGHT:** 230.42.

SYNONYM: *Bromated camphor*.

Formation and History.—Camphor unites directly with bromine in the cold without evolution of gas, forming bibromide of camphor ($C_{10}H_{15}OBr_2$), which was discovered by Laurent in 1840. This compound is unstable, being decomposed even by the atmosphere. In 1861, Th. Swartz found, that when bibromide of camphor is heated in sealed tubes, decomposition ensues, whereby hydrobromic acid is split off and a monobromated camphor compound remains, thus, $C_{10}H_{15}OBr_2 = C_{10}H_{15}OBr + HBr$. It was also shown that camphor and bromine heated together for 8 hours in sealed tubes, would accomplish the same result, and doubtless in this instance also bibromide of camphor is first formed. In 1865, W. H. Perkin,

independent of former investigators, prepared monobromated camphor while experimenting upon Laurent's bibromide of camphor, and named it bromo-camphor (*Jour. Chem. Soc.*, 1865).

Monobromated camphor was first experimented with, as a therapeutic agent, by Prof. Deneffe, of Ghent. In 1872, an article in its favor appeared in the *N. Y. Med. Jour.*, May, p. 522, from W. A. Hammond, M. D., and from this time numerous articles in the various medical journals created a demand for it.

Preparation.—The fact that sealed tubes were unnecessary for the practical preparation of the article was shown by Prof. Maisch, in the *Amer. Jour. Pharm.*, August, 1872. The writer recommends the following process, which varies somewhat, in certain respects, from that by Prof. Maisch, as one which he has employed quite extensively in his laboratory work: Take of camphor, in small pieces, 15 troy ounces; cold bromine, 16 troy ounces. Place the camphor in a tubulated retort, of not less than $\frac{1}{2}$ -gallon capacity, and connect the exit by means of a rubber tube, with a glass tube extending into ammonia water; then, through a funnel, pour upon the camphor 4 troy ounces of bromine. As soon as the temperature begins to rise, stop the tubulure of the retort, and occasionally agitate the contents. The mixture will partially liquefy, and the temperature will increase spontaneously, with evolution of gas, until about 71.1°C. (160°F.), is reached; from which point the heat must be continued by means of a steam or water-bath to 93.3°C. (200°F.). The flow of gas will now cease, and the stopper of the retort must be immediately removed, in order to prevent the ammonia being drawn into the retort by absorption of hydrobromic acid and the contraction of the cooling gas. When the contents of the retort have become cool, cautiously pour into it 4 troy ounces of the bromine, care being taken that the contraction caused by the bromine vapor coming into contact with the gas within the retort, followed by subsequent expansion, does not throw a part of the bromine upon the operator. Now repeat the preceding operation, and when the reaction ceases, cool as before. In like manner, add the remainder of the bromine in successive portions of 4 troy ounces, raising the temperature, as in the previous instances, to 93.3°C. (200°F.), after each addition. Lastly remove the stopper, and permit the contents to cool to about 10°C. (50°F.), and remain for 24 hours, when there will be a mass of crystals formed. Invert the retort, and permit the thick liquid to drain from the crystals; then pour upon them 16 fluid ounces of alcohol, and dissolve by means of a gentle heat and agitation; then decant the solution into an evaporating basin, and cool gradually, when crystals of monobromated camphor will separate; these should be purified by dissolving again and recrystallizing from their solution in 16 fluid ounces of hot alcohol. The yield will about equal the weight of the camphor employed. By-products are generated also by other reactions, so that the theoretical amount of monobromated camphor is never obtained. If the temperature of the bibromide be retained at about 10°C. (50°F.), by means of ice, no decomposition of bibromide follows. After the addition, each of the first and second portions of 4 ounces of bromine, in the foregoing process, decomposition of the bibromide ensues when the temperature reaches 68.3°C. (155°F.). It is not advisable to permit the temperature, at any time during the reaction, to exceed 93.3°C. (200°F.), as the reduction of the bibromide will have occurred at this point, and when too great heat is employed volatilization of the contents of the retort ensues, and to some extent, destructive decomposition, with formation of a black oil (perhaps containing finely divided carbon), difficult to remove from the crystals. The hydrobromic acid forms bromide of ammonium with the ammonia water, and this salt may be obtained by evaporating the solution of ammonia after the reaction.

Description.—"Colorless, prismatic needles or scales, having a mild, camphoraceous odor and taste, permanent in the air, unaffected by light, and neutral to litmus paper. Almost insoluble in water, freely soluble in alcohol, ether, chloroform, hot benzin, and fixed and volatile oils; slightly soluble in glycerin. It is also soluble, without decomposition, in cold, concentrated sulphuric acid, from which it separates again unaltered, when the solution is poured into water. It melts at 76°C. (168.8°F.), and sublimes at a slightly higher temperature. At 274°C. (525.2°F.), it boils without decomposition, and is finally volatilized without leaving a residue"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Monobromated camphor was first introduced to the profession, as a sedative to the nervous system, by Prof. Deneffe. M. Bourneville, who experimented with it upon different animals, as cats, rabbits, guinea pigs, and frogs, concluded, from the results obtained, that this article diminished the number of pulsations and determined a contraction of the auricular vessels; that it diminished the number of inspirations, reduced the temperature in a regular manner, and that it possessed undeniable hypnotic properties, appearing to act principally upon the cerebral system. Its continued use, at least with cats and guinea pigs, determines a rapid emaciation. The diseases in which it has been extolled as a remedy, are certain forms of *mental alienation* with excitation, *chorea*, *paralysis agitans*, *fevers*, and *acute diseases*, *hysteria*, *delirium tremens* (when wild, and the temperature is increased), *convulsions of children*, especially when due to *dentition*, *insomnia*, *satyriasis*, *nymphomania*, *spasm of the glottis*, *nervous palpitation of the heart*, *pertussis*, *headache*, and *dyspnoea of asthmatic or cardiac origin*. In fully developed *mania* it is less useful than chloral, but may be employed where the mania is less pronounced and there is slight nervous derangement, with increase of temperature. Give 2 or 3 grains every 2 or 3 hours. In the *convulsive disorders of children* it is less valuable than chloroform to check the spasms when severe, but may be used in mild cases. One grain in mucilage may be given every hour to a child, and 15 or 20 grains are admissible in a day. According to Prof. Locke, it is a better agent to prevent the return of convulsions than to arrest them. It is likewise stated to have proved beneficial in *spermatorrhœa* with great nervous excitability. M. Lannelongue prescribed it with benefit in painful *cystitis*, when the pain is not the result of any organic lesion—*neuralgic cystitis*. Also in *cystitis* of the neck of the bladder, of congestive origin and associated with a vascular lesion of the neck, the result of various causes; if *vesical catarrh* be combined with the cystitis, the effect will be nearly null. If the vesical catarrh be slight, even when a more or less *acute prostatitis* is associated with the inflammation of the vesical neck, the effects will be well marked.

While many experimenters have highly praised this agent as a successful remedy in the affections above referred to, many others have repudiated it as being much less efficient than the alkaline bromides. This discordance of opinions, together with its disagreeable taste, has, in a measure, prevented its coming into more general use. The dose of monobromated camphor is from 3 to 30 grains per day, in form of pills, dragees, or elixir. An elixir has been proposed as follows: Take of alcohol (90 per cent), 4 fluid ounces; glycerin, 3 fluid ounces and 3 fluid drachms; water, 2½ fluid ounces; mix together, and then add monobromated camphor, 46 grains. Gently heat the mixture until the camphor is dissolved.

Specific Indications and Uses.—Simple insomnia, headache; mental excitement; delirium; hysteria: mild infantile convulsions.

CANELLA.—CANELLA BARK.

The bark of *Canella alba*, Murray (*Canella Winterana*, Gaertner; *Winterania Canella*, Linné).

Nat. Ord.—Canellaceæ.

COMMON NAMES: *White wood tree*, *Wild cinnamon tree*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 26.

Botanical Source.—*Canella alba* is a straight tree, from 20 to 50 feet high, with erect branches at the summit only. The bark is yellowish-white; the inner bark thick, smooth, and pale, with a biting, aromatic taste. The leaves are scattered, shining, and yellowish-green, obovate, cuneate at the base, dotted when young, opaque when old, and petioled. The flowers are terminal, small, and borne in clusters, and of a purple color; the petals are concave, erect, thick, and deciduous. Berry the size of a pea, fleshy, smooth, blue, or black, hot and biting while green; seeds generally 2. Stamens combined in a tube; anthers 15, resembling furrows; stigmas 3 (L).

History.—This is a South American tree, being indigenous also in sections of south Florida, and in many of the isles of the West Indies. The bark was introduced into Europe early in the seventeenth century. The corky layer of

the bark, which is of a silver-like color, is removed by beating and cutting, after which the commercial bark is obtained. The drug is exported only from the Bahama isles.

Description.—The bark is of a pale yellowish-white color (externally slightly yellowish-red with elongated scars disposed transversely), occurring in quills or hard, twisted pieces, with an acrid, peppery taste, an aromatic, clove-like, or cinnamon-like odor, and a short, white, granular fracture. On breaking the bark, numerous resin cells, appearing as orange-yellow specks, are scattered throughout the whiteness of the internal structure. Alcohol extracts its properties, the tincture being of a yellow color, and becoming white when water is added. It pulverizes readily, yielding a powder of a pale-yellow color.

Chemical Composition.—When the bark is distilled with water an essential oil may be had, of a dark-yellowish color, having a powerful aroma and intense acidity; a pound of the bark yields about a drachm of oil. Besides, analysis has discovered in it gum, starch, bitter extractive, resin, albumen, and various saline substances. Analyses were made by Henry (1821), and Petroz and Robinet (1822), the latter observers finding a body to which they gave the name *canellin*, subsequently (1843) shown, by Meyer and Von Reiche, to be identical with mannin, which exists to the extent of about 8 per cent. The last-named chemists showed the presence of *eugenol* in the volatile oil, and also demonstrated the presence of another oil bearing a close resemblance to the principal constituent of oil of cajuput. Two other oils were found, but have not been thoroughly studied. The ash was found to be largely calcium carbonate. No tannin is present in the bark.

Action, Medical Uses, and Dosage.—Canella bark is an aromatic stimulant and tonic, useful in *enfeebled conditions of the stomach and alimentary canal*. It is generally used in conjunction with other tonics. It is employed in the West Indies as a spice, and has been advised in *scurvy*, and in *chlorotic, post partum*, and *carcinomatous menorrhagia*. Some smokers add this bark to their smoking tobacco to remove the unpleasant odor from the tobacco, and to impart a degree of fragrance to their smoking-rooms. Dose, 10 to 40 grains.

Related Species.—*Cinnamodendron corticosum*, Miers; Jamaica. Used by the natives for the same purpose as the canella bark, for which it is frequently sold. *Cinnamodendron* bark contains tannin; hence its decoction yields a black coloration with ferric salts, thereby differing from canella bark, which it is thought to resemble in other respects chemically. The bark is grayish-brown or ferruginous in color, the corky warts leaving a nearly circular scar, instead of the elongated, transverse scar of the true bark.

Cinnamodendron macranthum, Baillon; Porto Rico. Yields a bark resembling the preceding, and is substituted for canella bark.

The barks of the above species and canella bark itself have been sold as Winter's bark (see *Winters*).

CANNABIS INDICA (U. S. P.)—INDIAN CANNABIS.

"The flowering tops of the female plant of *Cannabis sativa*, Linné: grown in the East Indies"—(U. S. P.).

Nat. Ord.—Urticacæ.

COMMON NAME: *Indian hemp*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 231.

Botanical Source.—*Cannabis sativa* is a herbaceous annual, growing from 4 to 9 feet high, covered with a very fine, rough pubescence, scarcely visible to the naked eye. The stem is erect, branched, bright-green, and angular. The leaves are alternate or opposite, on long, lax petioles, digitate and scabrous, with linear-lanceolate, sharply serrated leaflets, tapering into a long, smooth, entire point; the stipules subulate. The flowers are borne in axillary clusters, with subulate bracts; the males are lax and drooping, and branched and leafless at the base; the females are erect, simple, and leafy at the base. The calyx of the male is downy; of the female, covered with short, brownish glands. The fruit is an ovate, 1-seeded achene; the seeds are roundish-ovate, slightly flattened, 1 or 2 lines long, without odor, of a sweetish, oleaginous, unpleasant taste, and glossy, and grayish in color (L).

History.—Hemp (*Cannabis indica* of Lamarck), is indigenous to Persia and northern India, and is cultivated in many other countries. It is naturalized in North America, Brazil, and Europe. The hemp of this country (the preparations of which are often referred to as *Cannabis sativa* in contradistinction to *Cannabis indica*, an error which should not be continued), is identical with the Eastern plant in its botanical characters, but differs somewhat from it in its physical qualities, the India plant being more powerful in its effects on the system, and which is probably owing to the influence of climate, cultivation, etc., or perhaps, from the absence of some ethereal ingredient. In the Eastern countries an infusion of hemp, prepared with cold water, is much employed as an intoxicating drink.

Several native names are applied to different parts or products of this plant. Thus the leaves and smaller stalks, dried and broken coarsely, and intermixed with a few capsules, is known as *bhāṅg* (Hindustan), *siddhi* (Bengal), *sabzi* (Bombay), and *hashish* (Arabia). Our modern term *assassin* is said to have arisen from this word, the name *Hashhashin* (assassin), having been applied to a murderous Persian sect, which, in its religious rites, used hemp (hashish) to intoxication. *Bhāṅg* is almost tasteless, and is of a dark-green color. It is smoked with tobacco, or without the latter, but usually is incorporated into a sweetmeat known as *majun*. The flowering and fruiting tops, from which the resin has not been removed, are known as *ganja*, *ganjah*, or *gunjah* in India, and as *guaza* in London and other drug markets. These occur as compressed, brittle, brown-green shoots, or as stiff, ligneous stems with flowering and fruiting shoots attached, both varieties having a glutinous aspect. Like *bhāṅg*, it is without a pronounced taste.

The concrete resinous exudation of the plant is known in India by the name of *churrus* or *charas*. This is peculiar in being the production of those plants, scarcely more than 3 feet high, growing in elevated situations (6,000 to 8,000 feet, Jameson). The natives, clothed in leather apparel, run among the hemp plants, beating them, and thus gather the resin which adheres to their garments, from which it is afterwards removed by scraping. Or it may be obtained by rubbing the ripened fruit-tops between the hands, from which it is afterward scraped and formed into balls. This kind is most valued, and is known as *momeea* (waxen *churrus*). A third and more dangerous method is that of stirring dried *bhāṅg* and collecting the dusty, resinous powder shaken therefrom. Hemp has long been raised for its textile fibers and for its oily seeds. The fibers are largely used in making cordage, and the seeds for feeding birds, and for the expression of oil of hempseed, mostly prepared in Russia, which is used in mixing paints, and manufacturing varnish and soap, and has been used as an illuminating oil, though not well suited for this purpose. The Poles and Russians, it is said, eat the roasted seeds with bread as a condiment (*Amer. Ency.*, Hemp).

Description.—CANNABIS INDICA. "Branching, compressed, brittle, about 5 Cm. (2 inches) or more long, with a few digitate leaves, having linear-lanceolate leaflets, and numerous sheathing, pointed bracts, each containing 2 small, pistillate flowers, sometimes with the nearly ripe fruit, the whole more or less agglutinated with a resinous exudation. It has a brownish-green color, a peculiar, narcotic odor, and a slightly acrid taste"—(*U. S. P.*).
